Holman.	2-in. piston	1½	2.40	1.45	1½	0.99	2.99	58.7	58.0
Chersén.	2½-in. piston	1½	1.76	1.60	1½	0.99	1.63	43.7	127.0

which has already appeared in this JOURNAL, seems to show that in piston machines this ratio may be with advantage a very high one, the limit being reached only when the drill bends and breaks. But with hammer drills this limit is reached much earlier owing to the breakage of bits, pistons, anvil blocks and shanks of the drill steel. The Chersén machine with piston having a diameter of 2¾ in. and a 6-in. stroke exceeded this limit for 78-in. steel even when the air pressure was only 50 lb. per sq.in., and bent drill steel and broken bits resulted.

EFFECT OF SIZE OF BIT ON DRILLING SPEED

Nothing is more striking than the great increase in drilling speed corresponding to a reduction in the diameter of the cutting edge. With piston of the same size while using the same air pressure, the speed of drilling bears a fairly definite ratio to the size of bit used, the area of hole excavated, and the amount of rock broken. This is shown by comparing the speed attained by competing machines on the water holes when boring with starters and with finishing bit. Table I accompanying this article shows a remarkable rate of increase in drilling speed corresponding to the reduction of the diameter

drill and the Little Wonder and the Holman piston drills, all having a piston diameter of 2 in. and a 5- and 6-in. stroke, respectively, were hopelessly handicapped from the start by the mistake made in selecting wrong sizes of bits, for the Kimber machine had to excavate 67 per cent. more ground than the Gordon drill. The Little Wonder drill, whose performance in the test disappointed its agents, had to excavate 17.6 cu.in. more rock to gain only 3.7 in. extra depth of hole, and the Little Holman drill had to excavate 24 cu.in. more for a hole only 3 in. longer. The Gordon hammer drill put in holes 40.7 in. deep with only 52 cu.in. excavated. Of

I thought before the test that, owing to the use of an arm, bar and clamp being necessary, the difference in the ratios of actual boring time to total working time for hammer and piston drills would not be so marked on these fields as in America. On the surface in these trials, the highest average for a hammer drill was about 86 per cent. of the actual time and for the piston drill about 79 per cent. In narrow underground stopes the difference would be greater in actual practice, but chucks of piston drills have been so much improved lately that drills are changed almost as rapidly as with hammer drills.

*Brakpan, South Africa.

COMPARATIVE MERITS OF HAMMER AND PISTON DRILLS

I must again, in the light of the results of this competition and other later evidence, review the comparative merits of hammer and piston drills for work in hard rock under the conditions existing on the Witwatersrand. Generally these trials are held to have shown that the hammer drill is a more efficient machine than the piston drill: in other words a larger percentage of the total kinetic energy of the blow is spent in the useful work of cutting rock. This may be true, but in a hammer drill quite a large percentage of the total kinetic energy of the blow is spent in heating the steel and in overcoming the elasticity and inertia of the drill steel and of the striking pin or anvil block. The longer the steel, the greater is this loss, though in a piston drill it is not noticed so much as it otherwise would be since on the longer drill steel the cutting edges are narrower and

wear. There is the friction of the drill-steel during its stroke on the sides of the hole which prevents rapid reciprocation and causes a portion of the force of the blow to be uselessly expended against the side of the hole. This wears away the wings of the drill bit and causes more loss by these vibrations' increasing the vibration of the mounting, that was originally caused by a variation between the axis of the drill bit and the true axis of the machine. This vibration causes a bit on starting a hole to strike every time in a different place, thus throwing bending stresses upon everything and causing more rock to be cut than is necessary. This tends to cause rifled holes and increases the losses in friction. The chief causes of friction losses are bad design and undue wear of the chuck, chuck bushings and guides. Speaking from experience in Australia and on the Rand these losses are appalling; machines are allowed to remain be-

ready broken from the bottom of the hole and to churning up mud or dry cuttings in a hole. Working too long with blunted tools is another cause of loss for it causes the rock to be crushed rather than to be chipped from the bottom of the hole. The amount of this loss has to be balanced against the time lost in changing steel more frequently, and the cost of providing and sharpening extra steel. The amount of these losses in a piston drill is great, and it is said that a piston drill indicating 5 h.p. in cylinder uses only $1\frac{1}{2}$ h.p. in useful work cutting the rock.

Difficulties in using air expansively are not so great in hammer drills, as in piston drills, and indeed in many of the valveless drills expanding air causes the forward stroke, but it was not until recently that a piston machine had succeeded in combining the necessary drilling speed and power to reverse the stroke with the use of air expansively. That is another loss of power, as is the fact that the length of stroke in the piston drill is controlled by the operator.

LOSS OF POWER IN HAMMER DRILLS

Now the hammer drill as exemplified in the best types has not so many possible sources of lost power. Besides the loss of power due to the fact that greater expansion of the air is not effected, more power is required to produce rotation in a hammer than a piston drill, as the bit is pressed against the bottom of drill hole all the time. In most hammer drills there is not much room for improvement in theoretical efficiency, for the rock cuttings are ejected either by air, or by air and water, as soon as detached so that the bit meets solid rock every blow. Drills can be changed oftener with less loss of time and thus during drilling the bits are on the average sharper. The bit is kept cool. Friction on the sides is reduced as the bit is not withdrawn at each blow struck. In addition, there appears to be a better chance of applying the more efficient and economical force of electricity in the hammer than in the piston type of drill; indeed, the Box drill has been devised on this principle. Various practical difficulties, however, have so far retarded the successful development of electric drills.

I have now reviewed the chief losses of power in piston and hammer drills, but before inquiring how the work of the piston drill can be improved I must refer to the hammer drill as a practical economic machine for use in hard ground. The hammer drill is evidently a success in certain mining districts in North America, but so far as I know, the large size has not been able to gain and keep a place in competition with piston machines in the hard-ore mines of Australia, Rhodesia and the Transvaal. Improved types are, of course, always coming out, and I do not wish for a moment to state that it cannot compete successfully. But I have with me

KONOMAX AUTOMATIC PISTON DRILL

so have less work to do in excavating the hole. That this loss is serious is well shown in Table I.

It will be noted that the increase of drilling speed of the Gordon drill with $1\frac{1}{8}$ -in. bits is not nearly as marked as with the piston drills owing to this loss being greater with long steel. This increase amounts to only 16.7 per cent. in the Gordon drill against 90.7 per cent. with the $2\frac{1}{4}$ -in. Ingersoll. What the actual amount of these losses is with hammer and with piston drills is hard to determine experimentally. Gillette states that in driving piles 60 per cent. of the energy of the blow of the falling hammer is lost.

LOSSES OF POWER IN PISTON DRILLS

The losses of power are many in piston drills. There is friction in the machine itself, due to bad fit, poor lubrication, tappets, auxiliary valves and piston rings as well as slackness and leakage owing to

low month after month until, many times, a starter placed in the chuck and tightened up tends to describe a circle having a diameter $\frac{1}{2}$ in. or more larger than that of the bit. This is no exaggeration. A rigid inspection of all chuck bushings should take place every fortnight, and a starter should be tested for its eccentricity in all machines when tightened up.

Another cause of rubbing against the sides of the hole is unequal length of the wings of the cutting edge. Machine sharpening and the introduction, if practicable, of detachable bits tend to remedy this. The accompanying illustrations, taken from a paper by Mr. Mills in the *Journal of the Mechanical Association of the Witwatersrand*, show these conditions well. There is also loss due to lack of rigidity of the striking tool in the shaft and shank, as shown by Mr. Anderson's experiments which will be referred to later. Loss of power is also due to pulverizing rock al-

letters from mine superintendents in Victoria, Australia, and others in Rhodesia, and all tell a story of failure. In the 1903 trials held in Johannesburg, the Leyner drill failed to cut hard granite with the same relative air consumption as the best piston drills. When I last made inquiries it was in use in only two mines on the Transvaal and that in a small way. The trouble has been said to be that on the Rand the air pressures in use were not high enough for the attainment of maximum efficiency. Yet even with the low air pressure there has been much breakage of chucks and other parts, resulting in much lost time and increased cost of maintenance.

foremost engineering firm in its line in the world, and then brought back. It performed well in the recent trials, showing a good boring speed and was introduced to Rand rock and Rand mining conditions after the trials. The results so far have been disappointing so that at the present time the Gordon drill is used in very few, if any, mines on the Rand. As far as I can learn the troubles have arisen partly from drills' breaking and sticking in the holes and from unfinished holes, but mainly, however, from valve troubles, such as sticking, wearing and breaking of the valves, and from the breaking of striking pins, anvil blocks and even the pistons under the blows delivered with high velocity.

which, when many machines are used, becomes in time a considerable item. The drill appears as simple as it is possible to make it; but I believe strenuous efforts are being made to improve the drill and eliminate the weak points. Personally I think that it was a mistake to use a light piston hammer, weighing $1\frac{1}{4}$ lb., and working under a high velocity due to a long stroke (8 to 10 in.), which delivers its blow on a tappet or anvil block having a diameter of only $1\frac{3}{16}$ in. Indeed, one leading engineer on the Rand has figured that the force of this blow is more than any steel can bear. A shorter stroke and heavier hammer is, I believe, mechanically and theoretically a better arrangement, but the other arrangement had to be adopted to give the drill the shape and form it has.

WAYS OF IMPROVING PISTON DRILLS

Here on the Rand we are turning to our old friend the piston drill, and are asking where it can be improved and what can be done to increase its efficiency and reduce the losses mentioned. Friction in the machine itself can be reduced by improved design and by introducing some scheme for automatic or more continuous lubrication. This can be done. It is being tried in America by the Western Lubricating Valve Company, while here on the Rand one machine has an attachment which uses a semi-solid lubricant, and in the machine described later there is a special oil chamber. The Ingersoll ball-valve attachment makes lubrication when set up for running easier; but the kind of "miners" that are often intrusted with the running of machines on the Rand is shown by the remark: "I want an Ingersoll, as you can give it one dose of oil and it will run for the rest of the shift while the other must be oiled often," made by a former employee of the company for whom I am working when he refused to work with any other make of machine than an Ingersoll. This is no doubt a compliment to the Ingersoll, but the remark serves more to show the conditions under which too often rock drills have to work.

In machine drilling loss by vibration of the mounting must always exist, but it can, I think, be reduced by shortening the stroke and by increasing the number of blows per minute, and also by increasing the rigidity of the boring tool. This last can be effected by increasing the diameter of shanks employed by making all shanks up to $1\frac{1}{4}$ -in. diameter; by doing this, it is said that a gain in boring amounting to 20 per cent., as compared with ordinary steel, can be attained. Using a very solid turned-steel shank and shaft and a mathematically true detachable bit of his own invention, Mr. Anderson obtained results better than this. He claims to have increased the boring speed at the property of the May Consolidated Gold Mining Company from 6 holes to 12

PHOTOGRAPHS OF BOTTOMS OF DRILL HOLES; 1, WINGS OF BIT OF UNEQUAL LENGTH; 2, DRILL STEEL, SLIGHTLY BENT; 3 AND 4, DRILL STEEL BADLY BENT

Nor has our experience with small hammer drills on the Rand to date been a satisfactory one. There is no field for its use "Cripple Creek style" with solid steel and vertical or nearly vertical up holes. Here it must have a water or an air-and-water feed. The Leyner small drill (Rock Terrier) came and has apparently gone again. The No. 3 Murphy drill with water feed a year ago was going to solve our problem, but I cannot find any number in use anywhere here; so with the Hardsocg Wonder and others. The Gordon drill was tried, condemned and then improved with parts made by perhaps the

city necessitated by the long stroke. Trouble regarding the supplying of water to the drill has not been wanting; not only because the mines could not always supply water free from grit and at just the right pressure, for excessive pressures cause leakage, but also because the water in the mine is acid and it always manages somehow to get into the machine with which it is used. The results of corrosion are most surprising even after a relatively short time. Then there was the added expense of hollow steel and of water pipes and water hose which are a nuisance in stopes, and of the water itself

A New Plan of University Development

Details of Scheme for Amelioration of Social Conditions at Columbia
Submitted to the Applied Science Alumni and Graduates in Architecture

B Y J A M E S F. K E M P *

The alumni of the School of Mines of Columbia University and of the allied Schools of Engineering and Architecture held a joint dinner at the Hotel Astor, Feb. 17. Between 200 and 300 graduates were present, and addresses were made by Professors Van Amringe, Chandler, Munroe, Hutton, Hamlin and Kemp, and by Dean Goetze, and John B. Pine, of the board of trustees. The contribution of Professor Kemp touches upon some hitherto neglected phases of the university problem and as it may involve points not without interest to the many graduates of our other technical schools and universities, the paper is placed before the readers of the JOURNAL.

A PLAN FOR IMPROVING CONDITIONS IN COLUMBIA UNIVERSITY

For a long time past I have been impressed with some anomalous features in the social life of Columbia University, and after serious meditation upon the subject, I have concluded to maintain silence no longer, but to submit to the Applied Science alumni and especially to the graduates in architecture a plan for improvement. We are very much in the position of the shoemaker's children who go unshod—or, expressed in another way, we are confronted with abundant charity and yet none of it beginning at home—or in still different form, we have a dozen or so of preachers and no one of them practicing his doctrines in his own parish. Thus, year after year our professor of sociology discusses the amelioration of conditions downtown, or in the crowded quarters of London or in Mostar, Herzegovina, but whoever heard him refer to the Columbia faculty and its present disadvantages.

We have, again, several professors of economics and political science, all of whom and with some repetition among themselves discuss at great length tariff and free trade in China, Thibet and German New Guinea, but who never utter a syllable about the principle of protection as applied to their fellow members in the teaching staff. Therefore, as we all know the severity of conditions involving food, lodging, clubs and amusements in this city, I have addressed myself to the problem, and I now have the honor to present to this august and influential body the aforesaid plan for betterment.

In order to improve the conditions of living I have passed in review all sorts of schemes. We might consider, for example, transplanting the teaching staff in a body

to the heights of the palisades in New Jersey, just across the river, and starting a colony in the woods of the neighboring State. One or two of our courageous pioneers have already gone thither and the movement might appeal to our manliness in that it resembles the work of forefathers who cleared the wilderness. But it has the disadvantage of taking some people to the frontier who are not accustomed to its methods of life! What success, for instance, could my colleague the professor of dramatic literature expect to have, if he were forced to wield a real ax instead of a figurative one? And how could our grubbers after Greek and Latin roots make headway with those of an oak tree? Worst of all, how could we still maintain existence, even though our physical health were greatly improved if we were cut off from the life of the metropolis by the waters of the Hudson and nobody knows how many feet of silt and gravel on its bottom? When we turn to the hills of Westchester the same objections arise, or if we look toward Brooklyn—but of course Brooklyn would not answer.

Therefore Manhattan island alone remains, and on Manhattan the only available site is the southwest corner of the university grounds. Therefore, secondly, I propose the erection upon this site of a 45-story apartment house to be called the Cosmos. With the actual details of size I will not trouble you beyond saying that it should be 150 ft. (46.15 m.) square, and should have a well or hollow space in the center 50 ft. (15.3 m.) square, leaving thus a hollow rectangle 50 ft. (15.3) wide all around. The ceilings should be 10 ft. (3.07 m.) from the floors, and this height with a 1-ft. (0.3 m.) thickness of floors would call for a building only 500 ft. (153.8 m.) high, a very moderate altitude as buildings now go in this city. There is an excellent rock foundation, a magnificent view, nearness to the university, subway, trolley cars, Pabst's in Harlem—in fact all the advantages one could desire. Into the Cosmos I propose that all the teaching staff of the university and the librarian and president be gathered as a part of the terms of their appointments, and that they be provided with quarters rent free, but in accordance with the following general scheme. In the scheme the reward of good service is constantly held out in the form of advancement in the social scale. This advancement, always upward, takes place with one or two exceptions in a regular and systematic way,

and is suitably recognized and recorded in official titles.

At the bottom we should naturally begin with the assistants and the necessary space in the form of individual suites of two rooms each should be assigned to them. The senior assistants should have, of course, the outside rooms, and especially those in front. The newly appointed should have the darker rooms opening into the central well. This has the great advantage of making the home surroundings of these young men not too attractive. It is very bad policy to constantly tempt away from their duties those whom the weight and experience of years have not yet steeled into habits of industry. At present I have often observed that the fine views from the windows of the two dormitories, Hartley and Livingston, lead these young persons to spend too much of the day dreamily puffing a pipe and gazing off into space, without I have felt confident, having their minds fixed on eternal verities of science or mathematics, but presumably on the eternal feminine. If a young and impressionable instructor could look only into a well 500 ft. (153.8 m.) deep he would remain by preference at his desk in the laboratory or museum where anxious seekers after knowledge or fossils or minerals could find him.

OFFICIAL TITLES

The official titles of these young persons should also correspond. Thus we would have duly recorded in the catalog used in our official relations: First-Floor-Back-Entry-Assistant Rogers, Second-Floor-Front-Entry-Assistant Kirk, etc. As we rise in the scale to the tutor's and instructor's grade, on the next floors it would be necessary to have larger suites, in fact, those of sufficient extent to give each man at least one outside window. Instructors in particular should be provided with suitably commodious and extensive quarters. In official life titles similar to those just mentioned would, of course, be employed. Thus, Third-Story-One-Front-Window-Tutor Morrison; Third-Story-Two-Front-Windows-Tutor Doctor Jouet; Fourth-Story-Two-Back-Windows-Instructor Judd; Fifth-Story-Front-Bay-Window-Instructor Berkey, etc. You all see how it would naturally develop—just like the Mandarin of the yellow button, Cheng Fong Wing, or the Mandarin of the three green buttons and the yellow jacket, Ting Tang Tong. We have abundant familiar precedents.

*Professor of geology, Columbia University.

Next above would come the adjunct-professors with properly expanding accommodations. If you should hear, for example, Eighth-Floor-Front - Adjunct-Professor Campbell, you would know at once that said incumbent was in his second year as adjunct-professor and had reached the front apartments. Tenth-Floor - Front - Adjunct - Professor Mayer would imply quite long service.

Next above would come the professors again with expanding quarters and, of course, with fewer to the floor. Thus if we heard the title Sixteenth-Floor Five-Back - Windows - and - Portico - Professor Walker, we would know that Professor Walker was new at the business, but that he had one of the finest suites assignable under the rules. Twenty-Fifth-Floor-Southern-Exposure-Professor Peele would imply a moderate number of years, but of distinguished service. And so on to the top of the professors' stories.

Now all of these apartments thus far mentioned being assigned by seniority, it would be necessary when anybody was promoted, or died or resigned, to all move up one, two, or five places as the case might be. Within the grades care would be exercised to have the apartments sufficiently similar in size and arrangements to facilitate the removal of furniture, since, of course, with promotion from a lower grade to a higher every man naturally expands. Statistics show that an assistant has, as a rule, two ordinary chairs, a morris chair, three sectional bookcases, three framed photographs, and an iron bed. A tutor adds a rocking chair, two ordinary chairs and three sectional bookcases, but usually the framed photographs by some strange process are now reduced to one, and almost always the occupant of the frame is a girl. An instructor adds various articles of furniture often including a high chair; an adjunct-professor still more, while a professor has a notable quantity especially of bookcases, which he seldom, if ever, opens. By a little ingenuity a scheme could be readily devised whereby the rooms could be divided off into imaginary squares like a map in an atlas, so that a tag on a chair reading G 12, would enable the skilled force of janitors to put the chair away at once.

ADVANTAGES OF THE SYSTEM

There is one additional great advantage in this progressive system of titles which makes them infinitely superior to the one now prevailing. We have, as you know, the Lieber professor of history, the Jay professor of Greek, and others of similar character. Now when in the faculty meetings the president calls upon the Lieber professor of history, it is objectionable for two reasons. In order to have his German correct the president ought to say, "the Lieber herr professor," and not so doing he sets a bad example to those pro-

fessors who, not being well trained in German, might make the mistake outside. In the second place it draws objectionable comparisons. Why should one individual be the president's or university's one Lieber professor and all the other be grouped in a bunch not dear to him or it? How much better to say, "The Thirty-ninth-Story-Front-Professor of History."

Again, imagine the distressing experience of our colleague who is addressed month after month and in the most public way, as the Jay professor. How much better to say, the Fortieth-Story Front-Corner Professor of Greek.

There are thus many minor arguments in favor of the plan and others would doubtless occur to one on reflection. But you will say no mention has been made of the deans of the several faculties. That is true, and at the outset I was much puzzled myself. If they were placed on the floors above the professors what could we do with them when they resigned and now that so many terms of office are so short, how could we provide for them in a plan that is fundamentally progressive? How provide, moreover, for our numerous acting deans? But all these difficulties have recently been dissipated because, as we all know, the deans, like the snakes in Ireland, have begun to swallow each other, and in a year or two there will not be any at all.

The Theodore Roosevelt professors on their return ought, however, to have the 41st floor, and with them should be quartered the Kaiser Wilhelm professor in a fine and suitable suite, the best the university could provide. Somewhere in this region should be the librarian. I have hardly known where to classify him; but then, for that matter, neither did the president and trustees for quite a good many years. Next above should naturally be placed the president with the entire front of the house and so much of the sides as might be necessary. In the rear might be placed the secretary of the university.

THE CROWNING FEATURE

There remain still two or three stories, and these are, of course, to be reserved for those venerable men of emeritus grade who have retired on the Carnegie foundation. At present they are forced to seek the fresh air, fine views and reduced rents of the country. But in the upper stories of the Cosmos they would have all the fresh air and the views without any rent whatever. It is but proper to recognize long service by assigning to these officers the most desirable quarters in the entire structure. Besides this arrangement leads naturally to the final feature in the plan; I am led to suggest this feature by three important considerations: (1) From deep interest in the work of my colleagues in archeology, Egbert, Wheeler and Gotthelf, I desire to see their successors a few millenniums hence provided with good and significant records for the study and re-

production of these times. The records should take the forms with which archaeologists are generally familiar and which they understand. (2) I have often been impressed as I have walked round and round this campus with the anomalous condition that now prevails, in that we have a long row of cinerary urns and not a sinner in them. (3) All the philanthropists and benefactors of today have been so exclusively wrapped up in aiding people to live that they have overlooked the extremely serious situation which arises when a man in New York is confronted with the bills for his funeral and interment. Cemeteries are fearfully expensive things, and there is no Carnegie foundation on which we may fall back. Therefore I propose that every person on accepting an appointment in Columbia University should express his or her approval of cremation. A crematory should then be constructed on the roof of the Cosmos building to which all should naturally come. The department of metallurgy should be requested to compound an absolutely resistant and indestructible alloy, such as phospho-molybdenum bronze or several others which will occur to some of you. From these, suitable cylinders can be prepared with caps that screw tightly on. Upon the outside is to be engraved a sketch of the life and services of him whose ashes repose within. The inscription should be so expressed as to throw light on the history of the times.

I propose to recompense the department of metallurgy for their invention by turning over to them all the gold and platinum which would be caught in the crematory furnace from the fillings of teeth, etc. The cylinders are then to be stored away as follows: Presidential ashes in the bowls of the fountains in front of the university; Theodore Roosevelt professors and librarians in the urns on One Hundred and Sixteenth street; professors and adjunct professors in the urns on Amsterdam avenue and Broadway; instructors in the urns on One Hundred and Twentieth street. Holes are to be drilled in the granite and the cylinders, which would be naturally about a foot long by an inch in diameter, will be hermetically sealed therein by some indestructible cement. The funeral services will be simple. For presidential funerals all the staff would be ordered out. For others only their colleagues in rank. They would march in gowns and with hoods either inside out, or upside down, like reversed muskets, and the chaplain would perform a service like laying a corner stone on a small scale.

But some one remarks what about the ashes of the tutors and assistants? Well that does not seem to me a very serious question, but I would suggest that they be strewn on the grass of the campus, so that after decease everybody could continue to walk all over them, just as has always been the case in life.

The Coal Mining Industry in Bengal

The Indian Miner Is Paid 12c. per Day and Can Save 4c. from this Income. With Help of His Wife and Family, He Mines 96 Tons per Year

B Y G L E N - G E O R G E *

Coal occurs in India over a widespread area, ranging from the hill coalfields of Assam in the north to that of Hyderabad in the south. The coal measure formations are exposed over a large part of this area. There are some 37 fields having an estimated approximate area of 30,000 square miles. But of these, only 8 are worked to any extent, while of the total output of India 85 per cent. is raised from the three coalfields in Bengal, those of Raneeunge, Jherria and Giridih. In view of the importance of these three Bengal fields compared with other districts, the following remarks will refer primarily to them.

Regarding the geological horizons on which coal occurs in India, the adopted classification of Indian strata differs from that of Europe and America, so that any correlation must be approximate. The

HISTORY AND GROWTH

Coal was worked in Bengal in the Raneeunge field as far back as 1777, while by 1830 several small collieries had been opened out. In 1843 the Bengal Coal Company was formed, which, from a small beginning has risen to an output of 800,000 tons a year and holds a large area of coal lands. In 1868 a railway line was carried to the Giridih field, which was then opened up chiefly by the East Indian railway, which company now produces about 750,000 tons per annum. The third field, that of Jherria, is of more recent development and the growth of its output has been a remarkable feature in recent years.

The situation of these Bengal coalfields near Calcutta and the cost and the better quality of the coal have been factors

The seams are almost always inclined, but not at steep angles, the dip being, as a rule, 1 in 10 to 1 in 5. Faults are not so frequent as to be vexatious. Igneous dikes, on the other hand, give a great deal of trouble and a considerable area of one of the best seams has been spoiled by them. They are of two types, dolerites, and mica-peridotites. They vary in thickness from 3 to 100 ft. or more, burning the coal on either side. Mica-peridotites have a tendency to flow along under the seam and consequently are more destructive.

As regards quality, the best Bengal coals are good. The defect of Indian coal is the rather high percentage of ash. On the other hand, the percentage of sulphur is low. The seams with the best reputations are the Sanctoria, Desherghur and Seebpore, of the Raneeunge field, Giridih

SURFACE PLANT AT BENGAL COAL COMPANY'S NO. 5 MINE

A NATIVE OWNED AND MANAGED MINE IN BENGAL

following is taken from a paper of T. H. Holland, Director of Geological Survey of India:

Indian Strata.	European and American Equivalents.
Jubbulpore series.	Jurassic
Rajmahal series.	Triassic
Panchet series.	Permian
Damuda series.	
Talehir boulder bed.	

The great coal-bearing strata is the Damuda series, called from the river Damuda, in whose valley the coalfields of Bengal lie. The total thickness in these fields is 8400 ft. The Damuda series in Bengal is subdivided as follows:

Upper or Raniganj (coal bearing, 5000 ft. in Raniganj field.	
Ironstone shales (no coal seams) 1400 ft.	
Lower or Barakur (coal bearing) 2000 ft. in Raniganj.	
3800 ft. in Jherria.	
114.	

*Deputy chief mining engineer, Raneeunge, Bengal, India.

which have caused their rapid development in the last decade. In 1898 their total output was:

	Tons.
Raneeunge	2,216,000
Giridih	653,000
Jherria	750,000
Total	3,619,000
In 1907, Raneeunge	3,980,035
Giridih	750,374
Jherria	5,179,185
Total	9,909,594

Development is still in progress and the output must farther increase.

GENERAL CHARACTERISTICS OF INDIAN COALS

The seams are thick on the whole, the majority of the seams worked being 12 to 18 ft. In a few cases beds 30 ft. thick are being developed, while in limited areas, seams 60 to 90 ft. thick exist, owing to the amalgamation of several beds.

coal and Nos. 14 and 17, of Jherria. Then follow a considerable number of seams slightly inferior, but still of fairly good quality. Following are some typical analyses, the figures representing percentage content:

(a) DESHERGHUR SEAM.

(1) Proximate analysis:	
Fixed carbon	54.33
Volatile carbon	33.77
Ash	9.47
Moisture	2.43
(2) Ultimate analysis:	
Carbon	69.19
Hydrogen	5.10
Oxygen	11.83
Nitrogen	1.59
Sulphur	0.37
Moisture	2.43
Ash	9.47

Calorific value, 6580 B.t.u.
Evaporating capacity, 8.8 lb. water per lb. of coal.
Specific gravity, 1.321.

(b) SANCTORIA SEAM.

(1) Proximate analysis:	
Fixed carbon	55.15
Volatile carbon	32.76
Ash	9.65
Moisture	2.44

(2) Ultimate analysis:

Carbon	71.93
Hydrogen	5.00
Oxygen	8.76
Nitrogen	1.82
Sulphur	0.40
Moisture	2.44
Ash	9.65

Calorific value, 6884 B.T.U.

second-class coals by picking, so far no systematic system of cleaning has been adopted.

DESCRIPTION OF COALFIELDS

The Raneegeunge coalfield lies 130 miles

coalfield. On the south, west and north the coal measures abut against metamorphic rocks. In shape the field is an irregular rectangle—the large diameter lying east and west—40 miles long by 5 to 17 miles in width. The coal deteriorates in quality in the extreme east.

The Raneegeunge coalfield is nearer to Calcutta and the seaboard than those of Jherria and Giridih by some 40 miles and being well served by railways, has a slight advantage in the matter of freight. The Upper or Raneegeunge measures are well developed (5000 ft. in thickness) and contain the best seams, the Deshergur, Sanctoria and Seepore, besides a number of seams not quite as good in quality. The Barakur series also contain a few seams of fairly good quality. The Ironstone shales yield a fair amount of iron ore.

While the exhaustion of the Raneegeunge field is far off, yet outcrop coal specially in the better seams has gone a long way to that stage. Future workings must be deeper, which will necessitate working larger areas from a single shaft or pair of shafts, and the employment of better machinery. All of this will tend to increase the capital expenditure and working costs.

GIRIDIH OR KURHURBARI COALFIELD

The Giridih field is situated some 70 miles or so northwest of Raneegeunge on the Barakur river, a tributary of the

THE BENGAL COAL COMPANY'S NO. 7 MINE SURFACE PLANT

Evaporating capacity, 8.55 lb. water per lb. of coal.
Specific gravity, 1.366.

(c) SEEPORE SEAM.

(1) Proximate analysis:

Fixed carbon	56.73
Volatile carbon	29.65
Ash	8.69
Moisture	5.02

(2) Ultimate analysis:

Carbon	70.67
Hydrogen	5.02
Oxygen	8.48
Nitrogen	1.62
Sulphur	0.55
Moisture	5.02
Ash	8.69

Calorific value, 6781 B.T.U.

Evaporating capacity, 8.43 lb. water per lb. of coal.

The above are probably the best seams in the Bengal coalfield. An average analysis of the second-class coals in the eastern half of the Raneegeunge field, is about as follows:

Fixed carbon	46.70
Volatile carbon	31.65
Ash	16.60
Moisture	5.05

A considerable number of seams coke well, but the percentage of ash in the coke is high. The method of coke manufacture is crude and wasteful—burning in open kilns—and yields only some 40 tons of coke per 100 tons of coal. A range of by-product ovens is being erected by the East Indian railway at its Giridih collieries. Although a great deal could be done to improve the sale and price of

WORKING ON THE OUTCROP OF AN 18-FT. SEAM, REMOVING THE OVERBURDEN

northwest of Calcutta, and the exposed area is approximately 500 square miles. On the east, the coal measures dip under newer rocks and their exact extent is unproved. That they soon reach unworkable depths has been shown by a recent deep bore hole some 10 miles east of the

Damuda. It is 11 square miles in area, only 7 of which are productive coal measures. In spite of its small area, this field had an output of 830,000 tons in 1905. Of this production, 700,000 tons came from the collieries of the East Indian Railway Company.

The main seam is 18 ft., while there are several other beds less in thickness. The quality of the coal is good and it ranks among the best Indian coals.

JHERRIA COALFIELD

The Jherria field, although the youngest of the Bengal districts, is now the first as regards output. It is situated on the Damuda river, some 40 miles west of Raneeungee. It is an irregular rectangle, about 17 miles east and west, 7 to 9 miles north and south, and is 200 square miles in area. The Lower or Barakur division is here greatly developed, being 3800 ft. in thickness and containing 18 seams. This field being comparatively new, only the shallow coal is at present worked, and costs are low. The quality of the fuel is good as Indian coals go.

The Upper or Raniganj series is not so well developed and contains four or five seams, none thicker than 8 ft., one of which—the lower—is considered first-class coal. The Jherria coalfield is well served by railways and a new Chord line, lately opened, has given it a greatly improved access to the up-country districts.

METHODS OF WORKING

The usual method of working is simple. The poor quality of available labor, the high cost of timber, the thickness of the seams render longwall out of the question, or even any method of taking out a very large proportion of the coal is difficult. The almost unvarying method consists in driving two sets of galleries at right angles, splitting up the coal into square pillars. The usual width of the galleries is 12 to 16 ft., while the size of the pillars varies from 30 to 70 ft. square, according to the depth. Roofs are good and timbering is the exception. On reaching a boundary, or in any favorably situated area, the pillars are split and worked as much as possible before the area collapses. The average percentage of extraction is about 60 to 70 per cent. of the seam.

During this operation, spontaneous combustion is apt to occur, and in several cases considerable areas have been lost by fire. In the Giridih coalfield the exceptionally good roof has led to a more scientific method:

When the pillar, say 40 ft. square, is to be worked, the lower 5 ft. of the 20-ft. seam is worked with the exception of four blocks or "chowkidars," each 6 ft. square, one at each corner of the pillar. Any timber is then withdrawn and the four "chowkidars" are blasted out, causing the upper 15 ft. over the whole pillar to come down, and bringing 1000 tons of coal on the ground. Where this method is used, the wastage of coal is as low as 2 per cent. So far workings are of a moderate depth only, a 400-ft. shaft being considered deep. However, some 800-ft. shafts are at present being sunk and the exhaustion of shallow coal will soon lead to deeper

workings and to some rearrangement of the system of working.

The occurrence of firedamp is rare, and safety lamps are the exception. The large size of the galleries and the number open, make the drag of the air currents small and in almost all cases natural ventilation, or turning the exhaust steam from pumps into a shaft, is found sufficient. In eight cases only have fans been erected, but soon deep workings must lead to a large increase in their number. Water is usually met with in fair, but not great quantities. In brief, it may be stated that coal mining in Bengal, so far, has presented no great difficulties from the engineering point of view.

The death rate of persons employed is low—0.76 per thousand miners above and below ground, as compared with the American 1.69, and the English 1.24.

Steel headframes are preferred to wood, good timber being expensive. Tipplers and screens are comparatively rare, hand loading into wagons (the coal is carried in baskets by women) being the usual method. Some of the large companies, however, are using tipplers, and an elaborate sizing and screening plant is being erected at one of the East Indian railway's Giridih collieries.

The factor of safety in winding and haulage ropes is high owing to the poor class of men (natives) looking after them. Underground haulage is not common, while horse haulage is almost unknown—the miners pushing their tubs long distances. Outputs of collieries are small in comparison with their individual area. A production of 200 tons a day per shaft would be a fair output. When the exhaustion of shallow coal necessitates

The Engineering & Mining Journal, N.Y.

From the point of output, the death rate is high—7.47 per million tons, as compared with the 2.85 of America and 4.4 of the United Kingdom. Methods in the past have not been economical, large areas of pillars having been abandoned, owing to unskillful working. A great improvement has taken place in recent years.

MACHINERY AND EQUIPMENT

Concerning mine equipment, India presents the most startling contrasts. Alongside a fairly modern colliery owned by a European company, will be found a native-owned concern, winding its coal in bows by means of a woman gin. In the European companies the equipment is fair. As the depths are moderate and quick winding unnecessary, geared winding engines are the rule. There is a considerable number of direct-acting engines.

deep shafts, larger outputs per shaft must be obtained.

The solution will probably lie in the adoption of coal-cutting machinery. Such a machine for India must be simple, strong, and as light as possible. A long-wall machine is probably out of the question. The successful machine will undoubtedly be of the drill or puncher type. In two cases (at the Bengal Coal Company's Santoria colliery and at the East Indian railway's Giridih colliery) electricity is used for pumping, while a 500-kw. plant has just been erected by the Bengal Coal Company at its Sodepur collieries for pumping and haulage purposes.

In view of the large number of new collieries being opened, there is a large field for manufacturers of mining machinery, pumps, hauling engines and gen-

eral mining equipment. All machinery must be simple as the class of labor employed is poor, and engines must be designed to bear ill usage. A company has just been formed to supply electrical power from central stations and a large amount of electrical machinery will be required in the future.

LABOR

While Indian coal mining presents no great engineering difficulties as yet, the problem of securing intelligent labor is most perplexing. Labor is obtained locally and consists chiefly of the two low castes—the Bowries and Santhals—who are an aboriginal race. The Indian native is an agriculturist and has an almost passionate attachment to the land, and regards coal mining only as a disagreeable necessity, in spite of the fact that he can earn four to six times as much at the latter as at the former. This has led to the absence of the formation of any craft skill and the Indian miner is as bad a workman today as he was 40 years ago. He cuts only 96 tons per year, as compared with 572 of the American, and the 279 of the English miner.

The ordinary laws of wages and supply of labor do not affect him, as the idea of saving and accumulating money is altogether beyond him. He and his family can live on 3 or 4 annas a day (6 to 8c.), and as long as he has a little over for "grog" he has no thought for the morrow. In spite of the large increase in the number of mines, there has been but little increase in the amount of labor available and the competition between the various companies is keen.

The Indian miner takes down with him, his wife and family. He hews or rather beats out the coal and his wife and children carry it in baskets on their heads to the nearest tram line and tubs—often 500 ft. away. He gets paid 6 annas (12c.) per car of about 13 cwt., and while he could cut 4 to 6 cars per day, he refuses, as a rule, to cut more than one. He works on an average, 3 or 4 days a week. The present Indian mines, without any further development, if assured of a full and regular supply of labor, would probably be able to increase their output 50 per cent.

Working costs are fairly low, ranging from 48 to 56c. per ton exclusive of royalty. Where royalty has to be paid, it is usually 4 annas (8c.) per ton. Prices until of late have been low—as low as 64c. per ton at the pit's mouth. During the past two years, prices have risen considerably and \$1.60 at the pit's mouth is probably the average at present.

The coal trade suffers greatly from the lack of rolling stock of the railway companies and the complaints in Calcutta are loud and insistent at present. To give an idea of the magnitude of the industry, it may be stated that the capital of the lim-

ited liability coal companies (excluding private concerns) is \$17,000,000, while the present market value of their shares is nearly \$90,000,000.

A National Bureau of Mines

During the recent annual convention held in Indianapolis, by the Mine Workers of America, a resolution was passed favoring the establishment of a national bureau of mines and mining. It was said that the dominant political parties had placed in their platforms strong declarations favoring such a bureau, but nothing had been done by the United States Senate to ratify the House bill passed in that body last May. The miners claim they have had reason to believe the measure would come through the Senate immediately upon the convening of Congress. Meanwhile, it is asserted that the death rate in mining is steadily increasing and the growing frequency of disasters due to poorly equipped mines are discreditable to the nation.

The plea of the miners is that congress inaugurate this work without further delay and restore confidence in political declaration as well as to accomplish what is universally believed should be done. It will be the duty of the bureau to investigate the causes of disasters and to seek out and enforce the means by which they can be prevented.

Coal Mining in Nevada

The principal supply of fuel used in the State of Nevada has heretofore been shipped from the mines in Utah and Wyoming; however, the new coal operations at Coaldale, Nev., are showing up so well that it is probable the State will soon have a considerable fuel output to supply part of its own needs. At one of the Coaldale operations a shaft is down 208 ft., and at the bottom shows about 42 in. of coal. It is stated that a thorough analysis made of this coal shows 57 per cent. carbon, 0.5 sulphur, and about 25 per cent. volatile matter.

The seams are not uniform in composition, since there are several streaks of good coal varying in thickness from 3 to 5 ft., and separated by partings of less desirable coal. On the surface in this same district, there are seven parallel seams which average in width from 8 to 80 feet.

If the Nevada operators succeed in producing a good grade of fuel, there is no question as to a ready home market. It is estimated that the Coaldale mines can transport coal to Blair Junction, the nearest railway point, for not more than \$2 per ton; the railroad will haul the coal to Tonopah and Goldfield for \$1.50 per ton. This would, therefore, enable the consum-

ers to purchase coal at a price of approximately \$10 per ton, which would be considerably less than the average price now paid.

There are many indications of coal throughout the entire region, and when the many oil concerns that are now drilling in the district have finished their borings, it is almost certain that their development work will disclose good coal seams of considerable area. It is stated by those who have visited the region that the coal here found will make a good grade of coke, and that the product will not slack when exposed to the elements.

The Instruction of Miners in Rescue Work

At the experimental station established by the United States Geological Survey at Urbana, Ill., the miners are taught how to escape from a mine when an explosion occurs and breathing is made impossible. Escape is effected by using a helmet which is kept near at hand, and a jar of oxygen, which is strapped on the back.

In making experiments the Government experts burn a quantity of sulphur in an air-tight room, which makes the atmosphere so obnoxious it is impossible for anyone to breathe. Men who enter wear helmets on their heads and carry enough oxygen in jars on their backs to last for two hours. As long as this oxygen lasts they are able to remain in the room without discomfort. Without this preparation a man could not enter the room and live to exceed one minute. Those who have entered the "death chamber" with helmet and oxygen breathed freely all the time.

The Indiana officials and operators are greatly interested in the rescue apparatus and will go to Urbana and visit the experimental station.

According to T. H. Holland, director, Geological Survey of India, coal is the most valuable mineral product of India. Fully 90 per cent. of the output is consumed in developing home industry, in 1906 the total valuation of the output at the mines being above \$9,000,000. With the exception of about 5 per cent., all the coal produced comes from the Peninsula region where it occurs in the lower division of the Gondwana system. This corresponds approximately to the upper Carboniferous horizon. In other parts of India small bodies of coal are found in rocks of Tertiary age. The eastern Himalayan fields are the only known occurrence of Gondwana coal not in the peninsula.

Such items as government taxes, etc., that are out of the control of the technical management should be segregated from the operative costs that are used for comparisons of working costs.

Working Costs on the Rand

By W. FISCHER WILKINSON*

There was at the Transvaal mines during the year 1908, a general reduction in the cost of working calculated on the tonnage basis. The statistics of the mines probably exaggerate the improvement in the economic conditions. In comparing, for instance, the working costs of any mine with those of previous years, it will be noticed that in many cases part of the improvement is due to charging a lower amount than formerly for development redemption. The average grade of ore worked was lowered and consequently a larger tonnage is available for mining for the same cost of development. The cost per foot may not have been reduced during the year, but the cost per ton has declined automatically owing to the lower grade extracted. It is important to re-

during the early months of the year an interesting series of articles.

The accompanying table, compiled from the monthly statistics of the Chamber of Mines, shows the reduction in costs that was effected between January and September. This is the first year in which the Chamber has published costs and profits. They are, of course, costs and profits on working account and must not be taken to represent net profits.

There is, as remarked above, generally a wide difference between the working profits and the dividends, owing to deductions for profit tax, depreciation, interest on loans, debenture interest, etc. The real working costs are rather difficult to arrive at, owing to variations in practice in bookkeeping, but they are considerably more than the costs on working account, and have been estimated on an average at about 75 per cent. of the working profits.

An accompanying table, compiled from

In order to illustrate the effect of large outputs in reducing costs, an accompanying table has been compiled from the returns for the month of August. The Randfontein mines are omitted:

REDUCTION IN GRADE, WITWATERSRAND MINES.

	Value per Ton.	Costs per Ton.	Dividend per Ton.
1897	39 7s	29 6s	10 1s

member, in considering the industrial situation, that the ton of today is not the ton that was mined last year or in former years. Part of the reduction, too, shown in the statistics is due to the increased scale of operations, the fixed charges, for example, being proportionately less per ton.

Making allowance, however, for these points, which made a reduction in costs more apparent than real, there was no doubt a general reduction in the costs due to increased efficiency. The policy now generally adopted of working on a large

40,000 and upward	7	32 6	14 8	17 8

scale and of mining ore down to a minimum of profit certainly produces very low costs. Whether equally good results or better could not be obtained by raising the grade is an open question upon which the *South African Mining Journal* published

the returns of the Witwatersrand mines only, i.e., exclusive of the outside mines, illustrates the reduction in grade that has taken place since 1897 and gives the dividend profits per ton and the cost of working calculated as the difference between dividend and yield. It is, of course, not an accurate figure, as no allowance is made for profits appropriated to capital, and the figures have, therefore, only a relative value.

remembered that the total available ore supplies of the mine are increased by the lowering of the grade. The figures are instructive and indicate that it is uneconomical to lower costs too far at the expense of grade.

The City Deep and Brakpan mines developments (*Aust. Min. Stand.*, Dec. 23, 1908) clearly demonstrate that the Rand may confidently anticipate the recovery of high values from great depths. In the City Deep the reef was intersected at a vertical depth of 2865 ft., and to date the average reef width disclosed is 22 7 in.; the average value is 1 oz. 17 dwt. per ton. At Brakpan the conglomerates were cut in the No. 1 shaft at a depth of 3800 ft., and in the No. 2 shaft at 3695 feet.

*Mining engineer, London, England.
NOTE.—This is a part of the article reviewing mining conditions on the Transvaal, published in the *JOURNAL* of Jan. 9, 1909; it was omitted from that issue on account of lack of space.

The Verde Mine, Arizona

By GEORGE W. MAYNARD*

Doctor Douglas' interesting and instructive article in the *JOURNAL* of Feb. 20, 1909, on the early history of the Copper Queen, suggests that a statement about the beginnings of another great mine in Arizona may prove of interest.

In September, 1879, I went to Arizona to examine a number of mines and prospects which Gen. Jno. C. Fremont, at that time governor of Arizona, had brought to the attention of New York capitalists. The Southern Pacific railroad then had no connection with eastern roads at the south, so that to reach Arizona one had to travel via San Francisco through California to Yuma and then east to Tucson which, for many months, was the terminus.

My destination was Prescott, at that time capital of the territory, the nearest railway point to which was Maricopa, about 150 miles away. The stage was a canvas-covered hack of the variety known as a "jerky." We pulled out at 8 o'clock at night. The one other passenger was a Wells-Fargo messenger who produced a rite after crossing the Gila, the reason being that the stage had been held up there a few nights before. The town of Phoenix, now the capital, consisted of about half a dozen adobe houses and the "Palace Hotel" a combination of canvas and planks. In comparison with other western mining towns Prescott was really attractive with its spacious plaza, court house and a general air of neatness.

For about two months my time was taken up in visiting neighboring mining districts and in the examination of more or less developed properties and prospects.

General Fremont accompanied me in nearly all of my trips, which were made with exceptional comfort due to the kindness of General Wilcox, then in command of Fort Whipple, who loaned us a roomy army ambulance, a span of big mules and a driver. The daily intercourse with General Fremont enlivened by his accounts of his early explorations will always be treasured as the most delightful experience of my early western work.

The work in the field was followed on our frequent returns to Prescott during the long evenings by the brilliant conversation and Washington reminiscences of Mrs. Jesse Benton Fremont, the daughter of Senator Benton. Taken altogether that two months in Arizona was equivalent to a liberal education.

MAKES EXAMINATION

On the completion of the work for my New York clients and as I was about leaving Prescott, I was asked by one of the Prescott merchants if I would go into the

Black Hills about 30 miles north of Prescott and look at a copper prospect which he owned there. As the statement about the property appealed quite strongly to General Fremont we made an early start one morning, the General's son Frank accompanying us. We reached the foot of the mountain in the evening and camped that night. The following morning we took to the saddle and soon reached the summit of a ridge from which we had a view of the Verde valley made brilliant by the rising sun, an experience which can never be blotted from one's memory.

As all of my note books and copies of reports bearing upon my Arizona work at that time are buried in a store house I have to rely upon my memory for the following details of the examination. The outcrop and definition of the vein on the narrow plateau on the summit of the ridge was most impressive from a miners standpoint. The outcrop projected well above the surrounding surface, and was made up of malachite, azurite, chrysocolla and cuprite, a veritable flower garden, for a width of 15 ft. There had been but little surface stripping. For a short distance down the hillside the outcrop was readily traced but was finally lost sight of under a heavy growth of chaparral. The strike of the vein was apparently across a gulch but could not be definitely traced without tools for cutting down the undergrowth and breaking up the surface. About 100 ft. vertically below the outcrop an adit about 50 ft. in length had been driven 5 or 6 ft. into the vein at right angles to the strike. My impression is that it had not passed through the vein. In this cross-cut there was considerable chalcocite and some chalcocite.

The outcrops and also the ore in the adit were sampled, in the latter case the copper sulphides being separately assayed. The assays showed no precious metals in the oxidized ores, but did give to oz. silver (with no gold) in the sulphides.

On my return to Prescott I informed the owner that he undoubtedly had the making of a good mine but that as it was a smelting proposition nothing could be done at present, for the reason that there was no fuel in the country and ore could not be shipped when the nearest railway was 180 miles distant. As the Atlantic & Pacific road, now the Santa Fe, was beginning to be talked about I advised him to hold on. To this he responded "I am hard up and if you can let me have \$10,000 within the next 60 (?) days I will deed you a half interest in the mine."

On the strength of this proposition I sent a statement of my investigation to a party in New York, who with others was to pay me in about 90 days a considerable sum of money for some steel patents, asking for an advance of \$10,000 on account for the purpose of securing the half interest in the mine.

The telegraphic answer to my letter

read; "Take my advice and have nothing to do with mines."

That mine is the "United Verde."

Multi-Cipher Device

James Trevor in the *Aust. Min. Stand.* Nov. 18, 1908, describes a multi-cipher device devised by him and shown in an accompanying illustration. This device consists of two cylinders mounted loosely on an axle, but so arranged that they can be securely clamped together in any position. The axle rests in standards on a base board. In the illustration, *A* is the cylinder on which are the code words; *B* the one on which is the key to the code. *C* is a handle for aiding in turning the cylinders. In case one pair of cylinders is not enough other pairs of cylinders can be mounted on the same axle. A certain

MULTI-CIPHER DEVICE

phrase in the key is always selected as the one opposite which the keyword of the code is to be clamped. Each message is prefaced by a key word so that for each message the code is changed. This prevents easy deciphering of the code used, and the message can be read more easily than if a book has to be used.

The rock temperature in Bendigo mines, according to the report for 1907 of A. H. Merrin, chief mining inspector for Victoria, Australia, increases at the rate of 1 deg. F. for each 75 ft. below the zone of invariable temperature. At 4000 ft. the temperature due to the heat of the rocks is 110 deg. F. At this depth the temperature of the water issuing from the rocks is 114 deg. F. Under average underground conditions, when there is water in the downcast shaft, the actual temperature in the stopes will be somewhere between 75 deg. and 110 deg. F., depending upon the quantity of air entering the stope and the length of time the air is in contact with the rock before entering the stope.

*Consulting mining engineer, 20 Nassau street, New York.

Conserving Labor

Nothing could be more hopeful than the awakened interest in the preservation of our natural resources. We could not wish to discredit it; but it may be pertinent to ask, says *The Evening Post*, whether we understand what our real resources are, and whether we are not overlooking our most destructive forms of waste. Corresponding to the economist's three factors of production, there are three conspicuous forms of waste—waste labor, waste land, and waste capital. The greatest of these is waste labor, but it is the form of waste which is least understood and appreciated. It is the most important because it is the human factor which is being wasted, and the human factor has always and everywhere been the greatest factor in the production of wealth. Communities have grown rich in poor environments, and poor in rich environments, but no community ever grew rich while wasting its human energy; and it is doubtful if any community ever remained poor which utilized and conserved its labor power. Labor power, of course, includes mental as well as physical energy. That waste labor power is the form of waste least considered is shown by the fact that a great many people, perhaps a majority, not only do not deprecate it, but actually think it a good thing. A leisure class to consume the products of the workers is thought by many to be an economic necessity.

Of waste labor there are four principal kinds—the unemployed, the improperly employed, the imperfectly employed, and the voluntarily idle. Of these the least important is the unemployed, though it alone has received much attention. It is the least important because, first, it is normally and on the average the least efficient labor which remains unemployed; second, because the utilization of the labor power which is now going to waste at the upper end of the social scale will go a long way toward solving the problem of unemployment at the lower end of the scale.

By improperly employed labor is meant that which is engaged in acquiring rather than producing wealth. Enterprises whose sole purpose is to cause two dollars to emerge from the pockets of other men where one had emerged before, absorb a considerable fund of energy which ought to be concerned with blades of grass and similar things. It is unnecessary to mention the thief, the counterfeiter, the confidence man and the blackmailer. Their activities are already regarded as predatory rather than productive, and the law is doing what it can to stop them. From the economic point of view, however, there is no great difference between the counterfeiter and the adulterator of food and drugs, or the

manufacturer of shoddy; between the confidence man and the promoter of over-capitalized corporations; or between the blackmailer and a certain type of advertising agent who persuades you to advertise with him, not because it will do you any good, but because it will save you from harm. A really productive enterprise carried on by purely productive methods increases the wealth in the hands of other people in proportion as it is successful; and in proportion as a man grows rich in such an enterprise by such methods, he makes the country richer instead of poorer. The law-giver who can turn all our labor power, mental and physical, into such channels, will make the country so productive that nothing short of a foreign invasion or a geological cataclysm could prevent us from becoming rich, even if our material resources were as meager as those of New England.

By imperfectly employed labor is meant that which is employed productively, but less productively than it might be. Whenever there is a man doing unskilled work who might, had he received the proper training, be doing skilled work, or doing skilled manual work who might be doing the more highly skilled and more needed work of managing and directing, there is a case of imperfectly employed labor. It is as great a waste of productive energy as it would be to have good garden land used for pasturing long-horned steers. Here, again, is a statesman's opportunity for enriching his nation, by providing the means for economizing to the greatest degree the labor power of the people. Much of it is now going to waste, in the sense that it has to be utilized in ways which are of little value, merely because of its over-supply, while other kinds of work are suffering because of the scarcity of competent men. An industry can expand only so far as its rarest factor will permit. The rarest factor is managing ability, and any policy, educational or moral, which will increase the supply of managing ability will enable industry to expand and to absorb greater numbers of the unemployed.

The voluntarily idle are of two classes—those who have retired on a well-earned competence, and those who live on wealth which they themselves have never earned. The first class does not trouble us much in America. The American business man's habit of continuing to work after having accumulated enough to provide for all his possible wants is singularly economical of human energy, provided, of course, that his is a productive or really useful business. The longer he remains active, the greater the fund of productive energy at work in the community and the richer the community will grow. It is, of course, unnecessary to say that no one is idle who is fully occupied with some useful work, even though he be not actually

earning his living by it. Until recently, we have not been very much troubled with the second class, but our own prosperity is creating it and we need to look to the future. Here is another challenge to the constructive statesman. The loss of this kind of labor power is especially regrettable, because it is usually labor power of the very highest type which goes to waste in this form. It is the kind of power, which, if set to work, would increase the supply of the scarcest factor in the creation of wealth, both material and immaterial, and which would, therefore, strengthen society precisely where it is now weakest, and contribute most to our national prosperity.

The Arizona Copper Company, Ltd.

The annual statement for the year ended Sept. 30, 1908, of the Arizona Copper Company, Ltd., submitted to the stockholders in Edinburgh on Feb. 24, 1909, covers the operations of the Arizona Copper Company, Ltd., the Arizona Copper Company, of Arizona and the Arizona & New Mexico Railway Company. Profits for the year amounted to £288,138; and the surplus, after deducting preferred dividends, was £173,607. The balance brought forward from the previous year increased this surplus to £222,064 after carrying £90,000 to the reserve account. Out of the surplus the directors recommend that \$180,987 be paid in additional dividends.

The production of copper was 33,980,291 lb., which is greater than that of any previous year. The total ore mined amounted to 751,220 tons, 43.3 tons of ore being required for the production of one ton of copper. The first-class smelting ores yielded 6.64 per cent. copper while the concentrating ores gave 2.1 per cent.

Improvements included the installation of a new dust flue at the smelter and development work during the last half year amounted to 17,095 ft., exposing a large tonnage of low-grade ore and a fair amount of higher grade.

Some stocks of French coal companies sell at high prices. Thus a recent market report shows sales of Courrières, par value 100 fr., at 2900 fr. per share; the dividend for last year being 80 fr. Douchy, par 200 fr., dividend 50 fr., brought 1055 fr.; Ostricourt, par 500 fr., dividend 50 fr. sold for 2375 fr.; Grand Combe, par 250 fr., dividend 50 fr., sold for 1465 fr. The returns on the selling price at the rate of last year's dividends ranged from 2.1 to 4.7 per cent. Only expectations of a higher dividend rate would warrant some of the quotations.

Mine Labor and Accidents in the Transvaal

The number of laborers of all classes, skilled and unskilled, employed at mines and mills in the Transvaal at the close of 1908 was as follows:

Mines:	White.	Negro.	Chinese.	Total
Gold.....	19,605	104,826	12,275	136,706
Cool.....	426	9,018		9,444
Diamonds.....	739	7,803		8,542
Other.....	447	3,776		4,223
Total.....	21,277	145,453	12,275	219,005

White labor was 9.7 per cent. of the total; Kafir, 84.7; Chinese, 15.3 per cent. In December there were 159 separate accidents reported, the casualties from which were as follows:

Number:	White.	Negro.	Chinese.	Total.
Killed.....	8	69	2	79
Injured.....	25	94	3	120
Total.....	33	161	5	199
For 1000 employees.				
Killed.....	0.38	0.37	0.16	0.36
Injured.....	1.17	0.49	0.24	0.91
Total.....	1.55	0.86	0.42	1.27

During the year 1908, there were 777 persons killed and 1231 injured, a total of 2008 persons. Of the killed 65 were white men, 615 negroes and 97 Chinese; the respective proportions being 8.3 whites, 79.2 negroes and 12.5 per cent. Chinese.

Mr. Matthewson and the Smoke Case

By F. T. HAVARD*

In the conference of the counsel with Judge Hunt in the Anaconda smoke case, Mr. Matthewson described in detail and with much lucidity, the processes in use for recovering arsenic from the smelter fumes and dealt with the advantages, and the more numerous disadvantages of the methods proposed for overcoming what the farmers style the "smoke nuisance." Mr. Matthewson said that the arsenic in the ores varied all the way from minimum quantities to 2½ per cent., usually occurring in but small quantities. He stated further, that 90 per cent. of the ore which come to the smelter is sent to the concentrator where 50 per cent. of the arsenic is removed and thrown on the dump. Of the arsenic which reaches the smelter in the ore, some is dumped with the furnace slags, a part is recovered in refinery drosses, and the rest goes into the flue in the form of white fume, consisting principally of the oxides. He told how the arsenic is recovered from the fumes by redistillation and recovery, and advanced the statement that the method employed at Washoe is the most thorough known. In reply to a question from Mr. Kelley, the attorney of the Amalgamated, Mr. Matthewson said that there are only two other smelters

in the United States which collect the arsenic from the fume, one being at Everett and one at Salt Lake.

In telling the court of the methods by which arsenic might be extracted, Mr. Matthewson classified the methods used as follows: A—Cooling processes: (1) water spray; (2) admission of air; (3) radiation; (4) freezing. B—Filtering processes: (1) bag house; (2) friction; (3) centrifugal gas cleaners. C—The Cottrell method. In commenting on the spraying method he emphasized the difficulty of disposing of the acid mud formed, and stated that a plant sufficient for the Washoe smelter would cost \$3,000,000. He disposed of the bag-house method by saying that a sufficiently capacious plant would cost \$2,750,000, that the expense of its operation will amount to \$1850 per day, with a recovery of arsenic to the value of \$204, and that the life of the bags would be short. The installation of a radiation-cooling system would cost, in his estimation, \$1,200,000, and would not be efficient. For the freezing system the pipes alone would cost \$4,000,000, and the cost of operation would amount to \$10,800 per day. The system, further, has not proved practicable. A plant using zinc oxide as a neutralizer would cost \$3,000,000, and would require 500 tons of zinc ore daily. With regard to the Cottrell method, Mr. Matthewson said that its application was not practicable on a commercial scale, except under very peculiar conditions.

He concluded that if the friction system now used at Great Falls were successful, Anaconda would adopt it, although its installation should cost \$2,000,000. Judge Hunt and Mr. Matthewson both stated that they had received many letters embodying schemes for collecting the arsenic, but in Mr. Mathewson's opinion, the men who had made the suggestions seldom realized the quantity of fume to be treated, and that consequently the ideas are of little value.

Steel Production in 1908

The production of open-hearth steel in the United States in 1908, as collected and published by the American Iron and Steel Association, was as follows, in long tons, comparison being made with the returns for 1907:

	1907.	1908.	Changes.
Acid.....	1,270,421	696,304	D. 574,117
Basic.....	10,279,315	7,084,568	D. 3,194,747
Total.....	11,549,736	7,780,872	D. 3,768,864

The total decrease in 1908 was 32.6 per cent. Acid steel was 8.9 per cent. of the total, and basic 91.1, in 1908; the proportions in 1907 being 11 and 89 per cent., respectively. Included in the totals for 1908 are 311,777 tons of direct castings, of which 156,772 tons were acid and 155,005 tons basic steel. This quantity of direct castings was 434,748 tons less than in 1907.

While the open-hearth production in 1908 was considerably smaller than in 1907, it was much larger than the production of bessemer-steel ingots and castings in 1908, the output of open-hearth steel in that year exceeding that of bessemer steel by 1,664,117 tons, or over 27 per cent. This is the first time that the production of open-hearth has exceeded that of bessemer steel.

The production by States for two years past was as follows:

States.	1907.	1908.
New England.....	239,797	158,417
N. Y. and N. J.....	706,019	350,348
Pennsylvania.....	7,808,353	6,266,372
Ohio.....	819,042	625,171
Illinois.....	1,019,451	483,101
Other states.....	902,674	997,460
Total.....	11,549,736	7,780,872

Pennsylvania made over 67.2 per cent. of the total production of basic-steel ingots and castings in 1908, and over 71.8 per cent. of the total production of acid steel against over 66.4 per cent. of basic and over 82 per cent. of acid ingots and castings in 1907. Ohio, Illinois, Alabama, Colorado and New York, in the order named, were the next largest producers of open-hearth steel in 1908.

The open-hearth steel made in 1908, including both ingots and castings, was produced by 125 works in 21 States and the District of Columbia. In 1907 there were 137 works in 20 States and the District of Columbia, which made open-hearth steel. During 1908 there were 40 open-hearth steel works which did not make steel, as compared with 25 works in the preceding year.

TOTAL STEEL PRODUCTION

The total steel production of the United States disregarding crucible steel, which has never exceeded 1 per cent. in any one year, has been as follows for 10 years past, in long tons:

	Bessemer— Tons.	Per Ct.	Open-hearth— Tons.	Per Ct.	Total Tons.
1899.	7,586,354	72.0	2,947,316	28.0	10,533,670
1900.	6,684,770	66.3	3,308,135	33.7	10,082,905
1901.	8,713,302	65.2	4,656,309	34.8	13,369,611
1902.	9,138,363	61.6	5,687,729	38.4	14,826,092
1903.	8,592,829	59.6	5,829,911	40.4	14,422,740
1904.	7,859,140	57.1	5,988,166	42.9	13,847,306
1905.	10,941,375	55.0	8,971,376	45.0	19,912,751
1906.	12,275,830	52.8	10,980,413	47.2	23,256,243
1907.	11,667,549	50.2	11,549,736	49.8	23,217,285
1908.	6,116,755	41.0	7,780,872	56.0	13,897,627

The make of bessemer steel in 1908 was smaller than that of any other year given in the table. The production of open-hearth steel, on the other hand, though less than that of any given year since 1904, was greater than that of 1904, or any preceding year. The total steel output was less than that of any year since 1901, with the sole exception of 1904.

The ratio of the total steel to pig-iron production was 87.2 in 1908, against 90.1 in the preceding year.

During the first 11 months of 1908, an average of 8081 stamps were dropping on the Rand, and the average duty per 24 hours per stamp was 6.21 tons.

*Mining engineer, Helena, Mont.

The Mineral Production of Canada in 1908

Total Mineral Production of Dominion in 1908 Valued at \$87,323,-849. Gain in Silver, Gold and Copper. Other Substantial Advances

B Y J O H N M c L E I S H *

The following tables and comments give a full preliminary report on the mineral production of Canada in 1908. The figures of production given are, of necessity, subject to revision, since at this time, in many instances, producers of metallic ores have not themselves received complete returns from smelters. For these and other reasons estimates have to be made. It is hoped, however, that this preliminary statement may give a fair idea of the gross output of the mineral industry during the year. Acknowledgments are due to the various operators who have promptly furnished statements of their production, to the provincial mineralogist of British Columbia for a complete preliminary statement of mineral production in that Province, and to the other provincial mining bureaus for assistance rendered.

The value placed upon the mineral production of the Dominion since 1886, when complete reports were first prepared, has been as follows:

1886	\$10,221,255	1898	\$38,412,431
1887	10,521,331	1899	49,334,065
1888	12,518,894	1900	64,420,983
1889	14,013,113	1901	65,804,611
1890	16,763,353	1902	63,211,634
1891	18,976,616	1903	61,740,513
1892	16,623,415	1904	60,073,897
1893	20,035,082	1905	69,525,170
1894	19,931,138	1906	79,057,308
1895	20,505,917	1907	86,812,765
1896	22,474,256	1908	87,323,849
1897	28,485,023		

The total value in 1908 was, approximately, $\frac{8}{7}$ times that shown in 1886. The increase in 1908 over 1907 was 0.5 per cent.; over 1906, it was 10.4 per cent.

This preliminary review of the mineral production in Canada in 1908 shows that the industry has in the aggregate more than held its own despite the large decreases in the prices of metals. That this falling off in prices has been an important and serious question for the metal-mining industries, will be better realized when it is stated, that had the metals, copper, silver, lead and nickel, maintained as high average prices in 1908 as in 1907, their total production in Canada in 1908 would have been worth over \$8,000,000 more to the producers than was actually the case.

The important feature of the mining industry during the year was undoubtedly the silver production, a total increase of over 72 per cent. being shown in the number of ounces produced. The metals, copper and gold, also show the important increases in quantity produced

MINERAL PRODUCTION OF CANADA IN 1908.

while iron, lead and nickel were produced in slightly smaller quantity than in 1907.

In the non-metallic class, decreases in gypsum and petroleum are more than counterbalanced by increases in coal, asbestos, natural gas, salt, etc. The portland-cement industry shows a small increase in sales and a large increase in quantity of cement made with large stocks on hand at the close of the year.

It should be noted that the valuation of the metals is based on New York prices, as reported by THE ENGINEERING AND MINING JOURNAL.

Some remarks are added on the details of production of the leading articles for the year.

GOLD

For the first time in nine years the gold output shows an increase over the previous year. The Yukon output in 1908 is estimated at about \$3,600,000, as compared with \$3,150,000 in 1907, while a considerably increased production is also shown in the province of British Columbia, derived chiefly from the Trail Creek ores, the placer workings having shown a smaller output. In Nova Scotia the output in 1907 was \$282,686. Complete returns are not yet available for 1908, but the output was probably not over \$225,000. Of the total gold output in 1908, over 44 per cent. was obtained from placer and hydraulic workings and 56 per cent. from sulphuret and quartz ores.

SILVER

The estimated silver production of Canada in 1908 was 22,070,212 oz., shipped as fine bars, silver bullion, and obtained in matte, ore, etc., as compared with 12,779,799 oz. in 1907, an increase of over 72 per cent. Owing, however, to the much lower price received in 1908, the total value shows an increase of only 40 per cent. Over 87 per cent. of the output was obtained from Ontario, and the increase is all to be credited to this province, since there was a slight falling off in the silver output of British Columbia.

The output from the Cobalt district in the province of Ontario again shows a very large increase over the previous year, nearly twice as much silver having been produced. Returns from 39 shipping mines show the ore and concentrates shipped, as approximately 25,497 tons, containing 19,296,430 oz. silver, as compared with 14,644 tons containing 9,082,363 oz. in 1907. Valued at the average price of refined silver for the year, the production in 1908 would be worth \$10,200,865, and it represents an average return of 756 oz. of silver or \$100 per ton of ore shipped as compared with an average return of 681 oz. of silver, or \$445 per ton of ore shipped in 1907.

If the output of this district continues to increase at the present rate, Canada will in the immediate future, become one of the chief silver-producing countries of the world. In 1908, it held probably the third place and furnished about 12 per cent. of the world's output.

COPPER

Statistics of copper production in 1908 show a total output of 64,361,636 lb., an

*Chief of Division of Mineral Resources and Statistics, Mines Branch, Ministry of Mines of Canada.

increase of over 14 per cent. over the production of 1907. There was an increase of over 900,000 lb. in the copper from the Sudbury mines, while preliminary statistics of production in British Columbia appear to show an important increase in production of over 7,000,000 lb. The total exports of copper in ore, matte and blister, were 25,568 tons.

LEAD

All of the lead production shown in the general table, 45,725,886 lb., was obtained in the province of British Columbia. The production in 1907 was 47,738,703 lb., valued at \$2,542,086; a decrease in quantity being shown of about 4 per cent. The total amount paid as bounty on lead production was, during the twelve months, \$139,064. The exports of lead in ore, etc., during the year were 2256 tons, and of pig lead 6971 tons, or a total of 9227 tons.

NICKEL

With the exception of the nickel contained in the ores shipped from the Cobalt district, the production of nickel in Canada is derived entirely from the well-known nickel-copper deposits of the Sud-

bury district. Previous to 1906 the output had been increasing steadily for a number of years. During the past three years, however, the production has not varied very greatly. About 815 tons less matte was shipped in 1908 than in 1907. The nickel contents were also somewhat lower in 1908, averaging about 45.1 per cent. as compared with 48.1 per cent. in 1907. On the other hand the copper contents were higher in 1908.

These figures do not include the nickel contents of the silver-cobalt ores from the Cobalt district, of which it is difficult to obtain satisfactory returns. The shippers of silver-cobalt ores receive little or no return for the nickel contents, although this metal forms an important constituent of the ore.

IRON AND STEEL

The total shipments of iron ore from mines in Canada in 1908 were 203,490 short tons, valued at the mine at \$486,857 as compared with 312,496 tons valued at \$666,941 in 1907. The greater part of this production was from the Helen mine, Michipicoten, delivered to Midland and Hamilton. During 1908 very little Canadian ore was exported.

Pig Iron—The total production of pig iron in Canada in 1908, from both Canadian and imported ores, according to direct returns from nine plants comprising 16 furnaces, was 630,835 short tons, valued at \$8,111,194, as compared with 651,962 tons, valued at \$9,125,226 in 1907. These figures do not include the output from the two electric furnace plants, making ferro-products, which are situated at Welland, Ont., and Buckingham, Quebec. Of the

stone flux charged was 483,065 tons. The plant of the Atikokan Iron Company, Ltd., was out of commission throughout the year, while a number of others were operated for a part of the year only. The blast furnace at Londonderry was in blast for little over a month and the furnace of the Deseronto Iron Company, Ltd., for about two months.

Steel—The returns from eight companies making steel showed a total output as in the accompanying table.

A statement of the bounties paid on iron and steel during the calendar year, furnished by the Trade and Commerce Department, is also given.

The rates of bounty issued were the same in both years.

ASBESTOS

Returns of shipments of asbestos from the eastern townships, province of Quebec, were received from 12 operating companies, which employed 2643 men in mine and mills and paid in wages \$1,002,768. Several other companies were engaged in development work and preparing to make shipments during the coming year. The total shipments divided into crude and mill stock in 1907 and 1908 are given in the accompanying table.

Exports of asbestos from Canada were: 1906, 59,864, value, \$1,689,357; 1907, 56,753, \$1,669,290; 1908, 61,210 tons, of \$1,842,763 value.

COAL AND COKE

Each of the coal-mining provinces except British Columbia, contributed an increased output to the coal production in Canada in 1908. The total shown includes colliery consumption and coal used in making coke. Of the total, Nova Scotia contributed over 59 per cent. Saskatchewan and Alberta over 19, and British Columbia 21 per cent. The production by provinces is given in the accompanying table, in short tons.

The total production of oven coke in 1908 was approximately 865,257 short tons, valued at \$3,668,074, being an increase of about 3 per cent. over the quantity pro-

NICKEL EXPORTS.

	1906.	1907.	1908.
To Great Britain	2,716,892	2,518,338	2,554,486
To United States	17,936,953	16,857,907	16,865,407
Total	20,653,845	19,376,335	19,419,893

Two companies are carrying on active operations: the Mond Nickel Company, at Victoria Mines, and the Canadian Copper Company, at Copper Cliff. The ore is first roasted and then smelted to a bessemer matte containing from 77 to 80 per cent. of the combined metals, copper and nickel, which is shipped to the United States and Great Britain for refining.

The accompanying table gives the results of the operations on the nickel-copper deposits of Ontario in 1906, 1907 and 1908, in short tons.

According to Customs returns exports of nickel in matte, etc., were, for twelve months ending Dec. 31, as shown in an accompanying table.

total during 1908, 6709 tons, valued at \$171,383, were made with charcoal as fuel, and 624,126 tons, valued at \$7,939,811, with coke.

The amount of Canadian ore, including mill cinder, etc., used was 219,266 tons, while the quantity of imported ore was 1,051,445 tons. The total amount of coke

STEEL PRODUCTION.

	1907.		1908.	
	Tons.	Value.	Tons.	Value.

used during the year was 817,746 short tons valued at \$1,770,320. The total amount of charcoal used was 1,121,920 bu., valued at \$85,738. The quantity of lime-

duced in 1907. The coke was made in the provinces of Nova Scotia, Alberta and British Columbia and entirely from Canadian coal. At the end of the year there

were in Nova Scotia about 659 ovens in operation and 173 idle; in Alberta and British Columbia on the same date 916 in operation and 528 idle, not including the ovens at Hosmer and Comox in British Columbia, from which no returns have yet been received.

PETROLEUM AND NATURAL GAS

The production of crude petroleum is, as usual, practically all derived from the Ontario peninsula. Direct returns from the producers have not been obtained, but the production has been estimated on the basis of the bounty of $1\frac{1}{2}$ c. per gal. paid by the Dominion Government. The total bounty paid in 1908 was \$277,193, representing a production of 527,987 bbl., com-

ASBESTOS PRODUCTION.

	1907.		1908.	
	Tons.	Value.	Tons.	Value.
Crude.....	4,327	\$830,633	3,346	\$692,232
Mill stock.....	57,803	1,654,135	62,188	2,855,275
Total asbestos.....	62,130	\$2,484,768	65,533	\$2,547,507
Asbestic and asbestic sand.....	28,296	20,275	25,239	25,829
Total products.....	90,426	\$2,505,043	90,772	\$2,573,386

ending November, 1908, were 1,600,934 cwt. valued at \$530,209. This is equivalent to 457,408 bbl. of 350 lb. at an average price per barrel of \$1.16. The imports in 1907 were equivalent to 672,630 bbl. valued at \$837,520, or an average \$1.24½. The duty is 12½ c. per 100 lb. There is very little cement exported from Canada, the consumption is, therefore, practically represented by the Canadian sales together with the imports.

COAL PRODUCTION IN CANADA.

Province.	1907.		1908.	
	Tons.	Value.	Tons.	Value.
Nova Scotia.....	6,354,133	\$12,764,999	6,539,866	\$13,138,124
New Brunswick.....	34,584	77,814	60,000	135,000
Saskatchewan.....	151,232	252,347	130,000	214,500
Alberta.....	1,591,579	3,856,286	1,845,000	4,890,011
British Columbia.....	2,364,808	7,390,306	2,329,600	7,280,000
Yukon.....	15,000	60,000		
Total.....	10,511,426	\$26,381,842	10,904,466	\$25,567,235

pared with a bounty of \$414,158 in 1907 representing 788,872 bbl. A decreased production of 33 per cent. is, therefore, shown.

Natural gas was produced in the counties of Welland, Haldimand, Norfolk, Kent, Essex and Bruce, in Ontario and at Medicine Hat, Alberta; the sales from the Ontario fields constituting over 95 per cent. of the total. The total receipts from gas sold in 1908 show an increase of about 24 per cent. over the receipts of 1907 and are now larger than at any time since the gas was first used.

CEMENT

Complete statistics of cement production in 1908 have been received from 23 operating plants. The total daily capacity of the 23 plants was about 27,500 bbl. as compared with an operating capacity of 14,300 bbl. in 1907. The operating plants were distributed as follows: One each in Nova Scotia, British Columbia and Manitoba, the latter manufacturing a natural portland, two in Alberta, three in Quebec province and 15 in Ontario. Of the 23 operating plants, 12 use marl and clay, 10 use limestone and clay, and one blast-furnace slag.

Detailed statistics of production in 1907 and 1908 are as follows:

	1907.	1908.
Barrels.	Barrels.	
Portland cement sold.....	2,436,093	2,665,289
Portland cement manufactured.....	2,491,513	3,495,961
Stock on hand, Jan. 1.....	299,015	383,849
Stock on hand, Dec. 31.....	354,435	1,214,011
Value of cement sold.....	\$3,777,328	\$3,709,063
Wages paid.....	956,080	1,274,638
Men employed.....	1,786	3,029

The average price per barrel at the works in 1908 was \$1.39 as compared with \$1.55 in 1907. The imports of portland cement into Canada during the 12 months

An estimate of the Canadian consumption of portland cement for the last five years follows: 1904, total, 1,694,988 bbl., of which 784,930 bbl. were imported; 1905, 2,264,106, imported 917,558; 1906, total, 2,814,267; imported, 694,503; 1907, total, 3,108,720, imported 672,630; 1908, total, 3,122,697 bbl., of which 457,408 bbl. were imported.

EXPORTS OF MINERAL PRODUCTS

Exports of metals and minerals from Canada for the year are reported by the Customs Department as follows:

Arsenic.....	Lb.	1,913,732	\$43,493
Asbestos.....	Tons.	61,210	1,842,763
Barrytes.....	Cwt.	3,509	13,690
Chrysotile.....	Tons.	4,571	56,864
Coal.....	Tons.	1,729,833	4,661,377
Feldspar.....	Tons.	9,524	34,045
Gold.....	Tons.		7,740,918
Gypsum.....	Tons.	280,091	324,574
Copper, fine in ore, etc.....	Lb.	51,136,371	5,934,559
Lead in ore, etc.....	Lb.	4,511,931	153,394
Lead, pig, etc.....	Lb.	13,942,663	469,060
Nickel, in ore, etc.....	Lb.	19,419,893	1,866,624
Silver, in ore, etc.....	Oz.	20,884,451	12,403,482
Platinum, in ore concentrates, etc.....	Oz.	43	937
Mica.....	Lb.	580,195	198,839
Mineral pigments.....	Lb.	249,635	4,850
Mineral water.....	Gal.	8,953	3,659
Ore, refined.....	Gal.	25	297
Ores, antimony.....	Tons.	149	5,647
Ores, iron.....	Tons.	4,334	72,260
Other ores.....	Tons.	13,910	509,779
Phosphate.....	Tons.	1	30
Pyrites.....	Cwt.	7,706	10,159
Pyrites.....	Tons.	17,283	96,600
Salts.....	Lb.	527,229	3,840
Sand and gravel.....	Tons.	298,954	161,387
Slate.....	Tons.	10,709	2,539
Stone, ornamental.....	Tons.	1,314	28,777
Stone, building.....	Tons.	4,009	14,034
Stone, for manufacture of grindstones.....	Tons.	661	5,991
Other products of the mine.....	Tons.		176,007
Total value.....			\$36,850,474

In addition there were manufactures exported to a total value of \$2,940,379; the important items of value being \$1,169,673 for manufactured steel; \$399,785 for 194,540 lb. aluminum; \$248,759 for 58,708 tons coke.

February Dividends

The accompanying table shows the dividends paid in February, 1909, by mining and industrial companies in the United States and by some foreign mining companies:

U. S. MINING COMPANIES.	LOCATION.	Amt. per Share.	Amount Paid.
Amal. Copper.....	Mont.	\$0.50	\$769,439
Bunker Hill Sulf.....	Ida.	0.25	75,000
Camp Bird.....	Colo.	0.24	196,800
Colorado.....	Utah	0.08	80,000
Elkton Cons. and M.....	Utah	0.014	37,500
Homestake.....	S. Dak.	0.50	109,200
International Nickel, pfd.....	N. Y.	1.50	133,689
Mohawk.....	Mich.	2.00	200,000
United Verde.....	Ariz.	0.75	225,000
Utah (Fish Sp's).....	Utah	0.02	2,000
Total.....			\$1,828,628

FOREIGN MINING COMPANIES.	Location.	Amt. per Share.	Amount Paid.

Total.....			\$205,230

U. S. INDUS-TRIALS.	Location.	Amt. per Share.	Amount Paid.
Cambria Steel.....	Penn.	\$0.75	\$675,000
Jeff. & Ctf. C. & I., pfd.....	Penn.	2.50	37,500
Phila. Gas, com.....	Penn.	0.75	498,600
Total.....			\$1,211,100

New Zealand Gold and Silver

Exports of gold and silver from New Zealand for the full year are reported by the Mines Department as follows:

	1907.	1908.	Changes.
Gold, value.....	\$9,867,118	\$9,743,275	D. \$122,843
Silver, ounces.....	1,562,663	1,731,536	I. 169,733
The gold bullion reported in 1908 was 506,381 oz. bullion, equivalent to 471,373 oz. fine gold.			

West African Gold Mines

Gold production in West Africa—including the Gold Coast and Ashanti—in January was 24,844 oz. bullion in 1908, and 22,817 oz. in 1909; a decrease of 2024 oz. The bullion reported this year was equal to \$442,804, or 21,810 oz. fine gold.

Colliery Notes

With reference to the observation of gas caps on safety lamps, the best authorities speak favorably of the use of a piece of blue glass in the foreground as a refinement that will enable the early detection of a blue gas cap on a small lighted oil wick.

Miners have a dislike for anything "new fangled," and consequently they view the advent of the rescue apparatus with feelings of distrust. When once they realize the true value of such apparatus, they will undoubtedly enter into the study of it whole-heartedly.

It is the habit of a gas to depart from the air currents and take up its abode in cavities along the airways. This is one reason why the reduction of pressure indicated by a fall in the barometer is dangerous; such an occurrence causes the pent-up gas in the cavities to expand in volume and mix with the air currents.

Henry Louis has called attention to the fact that our methods of testing for gas should be brought to a point of greater sensitiveness. The ability to see a cap is unequal among different men and consequently, the officials responsible for such testing should be required to undergo an examination. Colliery managers themselves may carry on such an examination by having a half dozen lamps burning in atmospheres of different kinds, and requiring the men to pass by one at a time and state what they can see. This test should be repeated at intervals, especially as the men grow older.

It is generally conceded that winding ropes constructed of steel wire are the best for colliery winding purposes. There is a divergence of opinion, however, as to whether the locked coil or the flattened strand ropes are best. Plough-steel locked coil ropes contain no hemp cores, consequently this class of rope is more rigid than the flattened strand variety. The latter class of rope possesses practically all the advantages of the former, and, furthermore, has no tendency to spin or kink. The flattened strand rope also exhibits less tendency to become brittle. Ropes of this construction are also easier to cap and to lubricate than locked coil ropes.

Warnings are of great benefit to colliery operators in enabling them to know when atmospheric conditions are dangerous. Henry Louis, before the Royal Commission on Mines in England, suggested that each colliery subscribe a small amount, say \$2, to defray the expense of a center, from which warnings could be sent to adjacent collieries stating the likelihood of a great atmospheric depression approaching the district. The warnings should be sent as far in advance as possible, because the atmospheric conditions of mines differ so much. Many mines will in-

dicate a change of the barometer before the barometer itself does, and others will answer much more slowly.

Basing his suggestion on the fact that a mixture of one-seventh of its volume of carbon dioxide to a mixture of firedamp at its most explosive point, will render the resulting atmosphere non-explosive, one mining engineer has proposed that a large furnace be erected near the mouth of each coal mine, and that sufficient carbon dioxide be generated to entirely fill the mine in a couple of hours, after which, all shots are to be fired. It is asserted by the same authority that this scheme will do away with the possibility of a dust explosion due to blow-out shots. The shots are to be fired by electricity, and after this has been accomplished, the fan is turned on full force so as to clear the mine of the gases that have been introduced. Mine operators will soon be dizzy trying to absorb the many ideas suggested to make their mines safe.

There is a certain amount of natural ventilation in all mines, and those with a temperature of more than 60 deg. at the working face probably contribute about 25 per cent. of the total volume of the ventilating current. It is always advisable to conduct the fresh air to the lowest point in the mine, and finish at the highest. Ascensional ventilation should be adopted so as to aid the fan wherever possible. One of the disadvantages of sprinkling in a mine is that the more vapor there is in the air the greater the strain on the work of the fan. Along this line it should be remembered that a waterfall in an up-cast shaft greatly retards a ventilating current. Instances have been recorded where an accidental fall of water in an up-cast shaft has been sufficiently detrimental to overcome the action of the fans and reverse the ventilation.

There has been much discussion of late as to the best standard of ventilation. The only practical method is to fix definitely the maximum percentage of marsh gas to be allowed in the return airway. Whenever the air contains a greater percentage of this gas than the amount prescribed, the ventilation should be considered foul. In dealing with ventilation in this way, the reason for fixing the standard, by prescribing a certain percentage of marsh gas, as the maximum permissible, is due to the fact that when a dangerous amount of carbon dioxide is present, the lamp would be extinguished before the gas would become dangerous to life. The greatest difficulty in fixing a certain standard of ventilation is the recognition that 1 per cent. of gas will create a condition of danger in a dusty mine, whereas 2 per cent. would not be any more dangerous in a mine free from dust. Any rules, therefore, will have to be modified in accordance with such conditions.

New devices and schemes for enabling the detection of small quantities of fire-

damp in a mine atmosphere, are being presented in rapid succession. One of the latest ideas advanced is to apply the microphone, by connecting this latter instrument in series with a telephone; when firedamp is present in the mine air, beats are sounded in the telephone located on the surface. The theory on which the scheme is based depends on the fact that if sound waves of two pipes of equal pitch impinge on microphones connected in series with a telephone, a clear note is heard, but if one of the pipes emits a slightly different note, there will be beats heard in the telephone. The practical arrangement is to have one pipe on the surface and the other underground; if firedamp is present in the mine, air of a different density will be blown into the underground pipe, which latter will emit a different note. The apparatus has already been tested in an atmosphere containing coal gas, and showed great sensitiveness. An admixture of but 0.1 per cent. firedamp gave three beats in twenty seconds, and an admixture of 1 per cent. gave 30 beats in twenty seconds.

Considerable care must be exercised when we attempt to dispose of gunpowder or dynamite. The *Engineer* suggests that the best way to destroy ordinary black gunpowder is to throw it into a stream under conditions that prevent any harm coming to human beings or animals through the dissolving of the saltpeter. If no suitable stream is available, the gunpowder may be poured out on the ground in a long thin line and ignited with a fuse at one end. To destroy dynamite cartridges, the paper wrappings should be carefully removed, the bare cartridges laid in a row with their ends in contact, and the first cartridge ignited with a fuse without a cap. Even with these precautions a simultaneous explosion of the entire mass may occur, so that it is wise to retire to a safe distance. The row of cartridges should be laid parallel with the wind and ignited at the leeward end, so that the flame will be driven away from the mass. Frozen dynamite should be handled with especial care, as its combustion is peculiarly liable to assume an explosive character. A small quantity of dynamite may be destroyed by throwing it, in very small bits, into an open fire, or the cartridges may be exploded one by one in the open air with fuses and caps. Dynamite should never be thrown into water, as the nitro-glycerine which it contains remains undissolved and capable of doing mischief. Other explosives which contain nitro-glycerine should be treated in the same way as dynamite. Ammonium nitrate explosives may be thrown in small fragments into an open fire, or, if they do not contain nitro-glycerine, may be destroyed by means of water. Explosive caps should be exploded singly with pieces of fuse.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Prop. and Pres. ROBERT McKEAN, Sec'y.
605 Pearl St., New York.
London Office: 6 Bouverie Street, London, E. C., Eng.
Cable Address "ENGINEERING, N. Y."

Subscription, payable in advance, \$3.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs. Notice to discontinuance should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsmen generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for February, 1909, was 42,000 copies.

March 6..... 12,000

March 13..... 10,000

None sent free regularly, no back numbers. Figures are live, net circulation.

A Tariff on Zinc Ore?

Our advices from Washington indicate that the Ways and Means Committee is likely to recommend a tariff on zinc ore. It will be a very serious matter if such a tariff be established, and the committee should consider it carefully. In the first place let it discard the mass of memorials and statistics by which it has been overwhelmed from both sides. To a large extent they reflect only brief periods when commercial conditions, always fluctuating, were especially favorable to one side or the other, viz., miners or smelters. The matter of cost of production is so intricate that two experts of long experience in the business might discuss it for a month without coming to an agreement. A committee of laymen can expect no result other than confusion in dipping into the technics of such a business. Consequently it should confine itself to viewing the broad principles.

The average price for spelter at St. Louis during the last 10 years has been about 5.05c. per lb. Under existing conditions, aside from any tariff change, there is reason to anticipate a higher range in the years immediately to come, perhaps 5.25c. On the latter basis a price of \$40 per ton for 60-per cent. ore at Joplin would leave but a narrow margin to the smelter. Yet, such a price for ore in the case of many operators at Joplin only meets the cost of production if all things be considered. Nevertheless, even so the mining of zinc ore is immensely profitable, inasmuch as the annual output of the Joplin district, about 250,000 tons, worth \$10,000,000, pays a royalty of about \$1,000,000 (in one form or another) to the owners of the land, who reap their profit while the operators may get none.

Now during the last decade there have been four years (of which three were successive) when spelter has averaged higher than 5.5c. per lb., and ore has fetched more than \$40 per ton without leading to a material increase in the production of the Joplin district. The smelters have had to go elsewhere for the supply of raw material necessary to meet the requirements of domestic consumption, first to Colorado and then to Mexico. The ore resources of Leadville have waned as well as those of Joplin.

If a tariff be put upon zinc ore the price of spelter will be jacked up sufficiently to enable the smelters either to (a) obtain

the necessary ore from Mexico and Canada at the increased cost, or (b) to obtain new supplies of ore from this country that normally cannot be produced profitably. There will be need for a careful adjustment of duties so as to keep out foreign spelter. If the latter be accomplished the only limit to the advance in price of spelter will be the point where consumption is restricted by users turning to cheaper substitutes.

Every cent that accrues to the pockets of the producers of zinc ore in the United States will come out of the pockets of American consumers. The smelters will pass on the advance to the galvanizers and brassmakers, and the latter to the users of the sheets and other manufactures. This phase of the question is self-evident. The miners want more money. Whence is it going to come? The middlemen—the smelters and the manufacturers of various degrees—may furnish it temporarily, but ultimately it must all be paid by the consumers.

Theoretically the smelter should not care what his ore costs (so long as he can sell the product at a proper profit), he being only a species of middleman. Practically he foresees that he will be driven among the rocks of shortage of ore supply, restricted consumption of spelter, and the competition of foreign smelters. These portend narrow profits, or none at all, and idle smelting capacity. All hope is to be abandoned of establishing an export trade in spelter or seeing the development of a smelting industry on the Atlantic coast. Just as the tariff on lead ore drove a smelting industry to Mexico, so will a tariff on zinc ore divert foreign ores to Europe.

As to the competition of European smelters we may form some idea from the plans of the iron-bound convention recently formed by them. This intends to control the price for spelter at London to a range of £20@23, or 4.35@5c. With the present duty of 1½c. per lb. on spelter the corresponding prices at which it could be entered at New York would be 6@6.65c. Practically, the condition that is threatening in the United States would be enjoyable to the European convention which would use America as a dumping ground, whenever necessary, irrespective of the price of 6c., the very purpose of the convention being to take care of surplus production. The source of that surplus production is Broken Hill, New

South Wales, where the ore is produced under conditions as to labor, etc., as costly as anywhere in the United States. The rise of Broken Hill as a zinc-producing district is due entirely to the efforts of engineers in solving one of the most baffling problems that metallurgy has known. One of the greatest triumphs in that district is owed to an American engineer.

The cost and profit in producing zinc depend fundamentally upon the grade of the ore yielded by the mines. The miners of Joplin, having exhausted to a large extent their richer ore, are now mining a lower grade than anywhere else in the world and have been able to do so only by the exercise of extraordinary ingenuity, but they suffer from an outrageous royalty system that hangs on their neck like the Old Man of the Sea. The States of the Rocky mountains have ore that is richer but of less docile character and are subject to higher freight charges because of their remoteness. Nor can it be said that they have approached their problems with the same persistence, intelligence and energy as has been done at Broken Hill.

It is, therefore, the problem of the Ways and Means Committee, and after it of Congress, to balance on the one hand the needs and demands of the miners of the United States; and on the other hand the rights of consumers, also American citizens, and the evident danger to the domestic smelting industry.

The British Columbia Copper Company

The report of this company for the fiscal year ended Nov. 30, 1908, shows that during seven months the mines shipped 319,527 tons of ore. At the smelter three blast furnaces in six months handled 321,427 tons of ore, which yielded 5,767,355 lb. of copper, 13,597 oz. of gold and 58,204 oz. of silver.

The cost per ton of ore handled, including all charges from ore in place to sale of the metal products was \$2.63 per ton; the cost of producing, refining and marketing per pound of fine copper, after crediting expenditure with value of gold and silver realized, was 9.996 cents.

It seems to us that this cost of \$2.63 per ton of ore is probably the lowest on record. It is the more remarkable in view of the high cost of coke at Greenwood. On the other hand, a favorable factor is

the self-fluxing character of the ore, the latter constituting practically 100 per cent. of the furnace charge. But however the conditions are regarded, the result reflects very high credit upon J. E. McAllister, general manager of the company, and especially manifests his success in effecting a coordination of the work of the different departments in such a way as to secure maximum efficiency all around. It is certainly extraordinary that it has been possible to mine and smelt a ton of ore for \$2.63, including freight on the metallic products to market, and refining and selling of the same.

The Osceola Report

The report of the Osceola Consolidated Mining Company for 1908 records once more the phenomenally low cost of milling achieved at its property. In the treatment of 1,426,329 tons of ore in 1908 the cost was only 15.8c. per ton, compared to 17.47c. in the previous year. We believe that these figures are unsurpassed anywhere. The betterment of conditions in 1908, with respect to material and labor, both as to the reduced wage for the latter and at the same time its increased efficiency, is reflected in the cost of mining and milling, which in 1908 was \$1.50 per ton of ore against \$1.84 in 1907. Consequently, although the yield of refined copper per ton of ore in 1908 was slightly less than in 1907, the cost per pound of refined copper was only 10.53c. against 12.44c.

We have frequently had occasion during the last 20 years to criticize unfavorably the policy of Mr. Bigelow, the retiring president, in some respects, although we have always commended the efficiency of his management with respect to mining and milling. We think that proper recognition should be accorded to the valedictory of the present management, given in its last official report as follows:

"As this is the last report which will be issued by the present management, they wish to place before the stockholders a judicial decision certifying as to their economical management of the property and as to the adequacy of the price realized through their selling agents for the product of the company. In the findings of fact by Judge Knappen, in his opinion

dismissing the bill against the Calumet & Hecla Mining Company, the court says: 'It is only just to the complainant (Albert S. Bigelow) to say that the charges made against his management of the Osceola Consolidated Mining Company to the effect that its product has not been economically manufactured and sold, and that it has not been made to bring the best prices, are shown to be without foundation.'"

Proposed Coal Mine Legislation

The budding agitation for reform in coal mining is beginning to blossom in the introduction of radical bills in several State legislatures. It is to be hoped that all of the measures finally enacted into laws will at least be based on common sense, even though they are not formulated by persons having an understanding of the coal industry and its problems.

In one State, legislation has been proposed that will prohibit the sale of fuel in which there is any foreign substance. Should this become a law, gas companies would have to furnish gas free from any air, and coal producers would be held liable if any of their product contained bone or slate.

It might be well to punish the tradesman who puts sand in his sugar or water in his milk, if he be not sufficiently punished by the loss of discriminating customers; however, the dealer who can sell pure fuel as the merchant sells pure food is a wizard who has certainly secured advanced knowledge of the science of the next century. Thousands of dollars have been spent by coal operators in removing bony matter from their coal, and they have then had no little difficulty in finding purchasers for their purified product.

There is so much coal legislation that is necessary, that the passage of ill-advised laws is to be deprecated. There has lately been a general cry for the conservation of our fuel resources; however, we shall not conserve our coal deposits nor the lives of our miners by adding any unnecessary burden to the industry. Let us have action that will permit the coal operator to inaugurate sane improvements rather than the making of laws that will force him to rob his acres and kill his men in order that his business may survive.

Views, Suggestions and Experiences of Readers

Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Mexican Zinc Ore

At this time when zinc-ore prices are depressed and there seems to be so much confusion as to the cause, any scrap of real information bearing upon the question is doubtless welcome.

With a view to getting at the facts in regard to the relation of Mexican imports to the downward trend of prices, I wrote to an old friend, a prominent engineer who is manager of a Mexican mining company in Chihuahua, asking him about the zinc resources of the Republic and received the following reply which may be of interest to the readers of the JOURNAL:

"The zinc industry is not in as flourishing condition in Mexico as you seem to think. * * * I know little of the occurrence of zinc outside of this state, but I believe this is the principal zinc producing state in Mexico.

"Zinc ores are found in the following camps: (1) Picachos, on the Kansas City, Mexico & Orient railroad, about 125 miles from the city of Chihuahua, where carbonate ores are mainly produced; sulphides occur but not on a commercial scale. (2) Santa Eulalia, about 16 miles from the city of Chihuahua, produces carbonate ore exclusively. (3) San Isidro, on the Chihuahua & Pacific railroad, about 140 miles from the city of Chihuahua, where sulphides alone are produced. At San Isidro the Sutton-Steele process of dry concentration is used with excellent results. (4) Almaloya, where carbonate and silicate ores are produced. (5) Parral and Santa Barbara produce sulphide ores only.

"The zinc orebodies are always found associated with silver-lead and in many cases the zinc is simply a by-product; although some mines, as at Picachos, are mined solely for zinc. It is claimed that there are, more or less exposed, in the state, 1,000,000 tons of ore, viz., Picachos, 50,000 tons; Santa Eulalia, 100,000; San Isidro, 200,000; Almaloya, 50,000; Parral and Santa Barbara, 600,000.

"The carbonate and silicate ores run from 32 to 45 per cent. zinc after being hand sorted. Crude sulphide ores run from 10 to 35 per cent. zinc. The sulphide ores present hard and complex milling difficulties. Formerly zinc was considered a detriment in the ore and such ores sold to the smelters were given a low zinc limit and charged for over about 5 per cent., losing thus the zinc and being penalized for its presence.

"The foregoing camps are producing almost all the ore that comes from this state, which for September and October was about 125 tons a day. Picacho ships carbonates, lead-free 45 per cent. zinc; San Isidro, sulphide concentrate, 45 per cent. zinc; Santa Eulalia, carbonate, lead-free, 35 per cent. zinc."

I simply give the foregoing as a statement of fact from which the reader can draw his own conclusions.

FRANK NICHOLSON.

Hazel Green, Wis., Feb. 16, 1909.

Assay of Gold in Copper Bullion

I was much interested in Doctor Hunt's description of the assay for gold in copper bullion by the sulphuric-acid method. I have been using this method for about two years, and have found the results to be very reliable as compared with those obtained by the "all-fire" method. In fact, it is my experience that the results are slightly in favor of the sulphuric-acid method.

However, I cannot agree with him as to the necessity for the use of cupric sulphate. It has been my method to use a solution of mercury nitrate or sulphate equivalent to 100 mg. of mercury, adding it directly to the copper borings, usually agitating it a little. Then add 80 c.c. of concentrated sulphuric acid, and place on a hot plate, boiling for three-quarters of an hour. Now cool and add about 400 c.c. of hot water, stirring it in gradually when all of the crystals will dissolve. Boil for 15 minutes; let settle and filter through a triple filter.

It has been my contention for some time past that the reason why the ordinary wet method gives low results is not because the gold goes into solution, but because of its very finely divided condition due to the violent reaction of the nitric acid, and that it is then carried through mechanically by the solution.

As a part proof of this theory, I have found that I can get results which compare favorably with the fire assay if I use a mercury salt. However, the results are not so uniform as in the case of the sulphuric-acid method.

The author of the mercury method always claimed that any sulphur present in the bullion will form a sulphide of mercury, and that this will take the place of lead acetate. It is also my experience that in low-grade bullion running from 10 to 50 oz., the silver is thrown down with

the gold, and I could find no trace in the filtrate. Of course there may be some bullions that may require some modification, but I have not come across them.

It would interest me and perhaps others if Doctor Hunt would explain his theory for the use of permanganate in the filtrate before precipitating the silver. I have found no difficulty in getting all of the silver down by simply adding salt solution to the filtrate without any preliminary treatment, of course, taking the precaution to add enough to throw down any mercury that may have been dissolved. My work has included material running from 10 to 600 oz. in silver.

It is not my intention to criticize Doctor Hunt. I am rather in hopes of hearing from others, as the all-fire method is expensive and takes such a long time, and a method such as the sulphuric-acid method seems to me would be a blessing to the assayer.

F. B. FLINN.

Newark, N. J., March 2, 1909.

The Value of Good Management

One of the first questions asked of a promoter by a capitalist, or successful investor, after having satisfied himself regarding the merits of an industrial proposition, is "Who is going to manage this business?" The successful mining investor also asks the same question, and if everyone made sure of this important point before putting his money into a mining enterprise, there would be fewer failures than occur at present in what appeared to be "sure things."

It is surprising what chances people will take in mining investments without asking who is going to manage the property after it is bought, so that it can actually be made to pay the returns figured out on paper. More often than not, the engineer who has examined the property for purchase, if any engineer is employed at all, is not retained to carry out his own plans and recommendations, and the man who is placed in charge—usually some friend or relative of the buyers—carries out his own ideas, regardless of the engineer's previous advice, and so the entire enterprise often fails. The engineer's reputation generally suffers in the process also, although it may be no fault of his, as people are apt hastily to judge these failures from the results alone. There is an old saying that figures can-

not lie, but they are apt to be most misleading unless you know who made them, and who is going to make them work out in practice. No really successful mining man would think of investing his money in a proposition in regard to the management of which he knows nothing, no matter how well it shows up, unless he simply intends to hold it, as a piece of real estate, for a natural rise in value. Men with promising properties are constantly asking engineers to interest investors in their properties, without explaining at all who will manage them, but no engineer feels justified in complying with such a request.

This subject has been so impressed upon my attention lately in several instances, that I should like to set forth my views upon it. I am inclined to place a value of about 75 per cent. upon the management of a new mining proposition, and something like 25 per cent. upon the merits of the property itself. Of course, there are exceptions to this rule, as to most rules, notably in the case of a very rich property which pays a good return in spite of the management—where the mine is said to have made the reputation of the man without just cause—but even then a man having better executive ability and who knew his business thoroughly would undoubtedly have produced better results. In my experience such men are most difficult to find, and are worth all the money you pay them. Generally, I think it is the custom to give the manager, besides his salary, an interest in the property as an incentive to do his best. I also believe it is very rare nowadays that such a man attempts to temporarily impair the value of a property for stock-gambling purposes. The manager's chief desire is to build the property up and make it more valuable all the time.

In speaking of the management of a property, I have two positions particularly in mind. It does not always follow that a capable superintendent, who is competent to handle the miners and other men about the mine and to get the best work out of them, is also equally able to pass upon the merits of a mining property or to plan out the proper work to be done. I believe these various vocations are special gifts from nature, and am backed up in my theory by knowing most excellent mine managers who have recommended very poor propositions to purchasers, honestly believing them good investments. It also follows that a good assayer or mill engineer, is not always equally as good in sizing up a mine. We are all specialists nowadays in our own field of work, and the results obtained from a harmonious combination of these different men is far ahead of what it used to be with only a general "handy man about the place." If, however, the

examining engineer has executive ability, a loyal and efficient superintendent or mine manager to carry out his ideas, and the responsibility for the success of the mine placed upon his shoulders, then the owners have the best chance of winning out, and the men in charge deserve all the benefits they may get.

Not very long ago, a mine owner used the argument to me that his mine ought to be a good one because he had spent over \$200,000 on it. However, in spite of this fact it was not. Another gentleman, who owned many large interests, all of which were uniformly successful, had invested heavily in a property years ago. It was a failure from the start, but still he had never been to see it himself, nor would he send an engineer to examine it and pass upon its value. Consequently, the mine has been shut down for years, and he keeps paying the taxes out of his pocket. These two cases were cited by the owners as results of bad management. In reality, they were not only results of bad management, but were primarily due to the lack of an examination by a competent engineer in the beginning. A poor mining property cannot be made to pay with the best management in the world, but a good one will pay in direct proportion to the management, and the better the management is the more confidence people will have in investing their money in it.

I am strongly in favor of placing a property in the hands of the engineer who examines it for the purchasers and of holding him responsible for the success of the investment. By this, I do not necessarily mean that he should live upon the ground, but rather that he should be retained as a consulting engineer, with his own superintendent or manager in charge, and should visit the mine occasionally to see that his plans are carried out. He should be given some interest in the property and should keep constantly in touch with the work as it progresses, making reports to the directors and fulfilling all the other functions of his position. The more properties this engineer can secure to handle in this way, the more valuable he becomes, as his experience in one place will help, not only him, but also the owners of the next mine.

A. P. ROGERS.

New York, Jan. 28, 1909.

The Steelton, Penn. Reporter says that a steel rail rolled by the Pennsylvania Steel Company, in 1876, for the Cumberland Valley Railroad was discovered the other day by James P. Gaffney, who was inspecting a lot of old rails sold by the railroad to a southern lumber company. The rail had been in use on the main line for 32 years and is still in serviceable condition. The date of manufacture is plainly stamped on the rail.

A Benefit Fund for Coal Miners Families

In view of the frequency of recurring accidents in the coal mines of this country and the recent movement to collect subscriptions for the benefit of those widowed and orphaned by certain of the more serious disasters, is not the time propitious for starting a "National Fund" to which every coal operator in this country—from Pennsylvania to the Pacific coast—should contribute monthly, or annually, a fixed sum per ton of product?

One mill per ton would seem to be within the means of the smallest operation. But such a fund, vested in and administered by a trust composed of three men of national reputation—appointed by the President of the United States—with the governors of the coal-producing States as an advisory commission would meet all requirements.

It would even seem that such a fund might be utilized to carry out important investigations looking to the development of safety appliances and improved methods on broader lines than those now being pursued by the Government.

In Pennsylvania a bill to tax coal operators with similar objects in view has been voted down on the theory that such a tax would ultimately fall upon the consumer; surely, a general contribution of 1 mill per ton would not be worth considering in such connection.

I hope that this idea may appeal to the readers of the JOURNAL sufficiently to excite discussion. If practical, it has great merit over any system of taxation. Is it practical?

OPERATOR.

New York, Feb. 20, 1909.

The European Zinc Convention

The organization of this convention comprises three groups of smelters, viz., (a) the German, including the Dutch and some of the French and Belgian producers; (b) the Franco-Belgian; and (c) the British. Among the important producers only Giesche's Erben remains outside, that famous concern adhering to its historic policy of independence. The German groups have incorporated as the "Zinkhüttenverband," with a capital of 2,047,000 marks, of which Fritz Lob is chairman. Mr. Lob is director-general of the Hohenlohe interests; the organization of the convention is largely due to him. The splendor of the German group is to be sold by the Metallgesellschaft, Frankfurt am Main; Beier, Sondheim & Co., of Frankfurt am Main; and Aron Hirsch & Sohn, of Halberstadt. These concerns themselves have large zinc-smelting interests. Production of all the groups will be regulated according to the plan that we have previously stated.

The Canadian Mining Institute

SPECIAL CORRESPONDENCE

The annual meeting of the Canadian Mining Institute opened in the Windsor Hotel, Montreal, Wednesday morning, March 3. At the opening session President W. G. Miller delivered a brief annual address. The institute, he said, was formed in 1898. It numbered then 63 members. Today there were 850. During the last ten years the institute had rendered valuable service to the mining industry in Canada. Several excursions had been organized by it, with the result that the mineral resources of Canada had been brought to the better acquaintance of mining engineers. Among the excursions organized, Mr. Miller mentioned that to British Columbia in 1899, that to the provinces of Quebec and Nova Scotia in 1900, which was organized with the American Institute of Mining Engineers, that to Cobalt in 1907, and finally the excursion of last year, which permitted the mining engineers to visit the mining lands of Canada from the Atlantic to the Pacific.

J. McLeish, of the Department of Mines, Ottawa, presented a report on the mineral production of Canada, a summary of which is given on another page. The reports of the officers and council were presented and approved, and other necessary business transacted.

The president's gold medal for the best student's paper presented at the last annual meeting, was awarded to H. H. Yuill, of McGill University.

J. Obalski, superintendent of mines for Quebec, presented a report in which he said the total mineral output for the province for 1908, valued at the mines, or at the nearest point of shipping, was \$5,493,664. The mining industries employed 6324 men, whose wages for the year amounted to \$2,024,357. The biggest item of production was asbestos, the output being valued at \$2,551,596. Cement came next with \$1,127,335.

TAXATION OF MINING LANDS

This subject was brought up at the afternoon session by a paper presented by E. L. Fraleck, of Cobalt. He pointed out the anomalies that existed, by which holders of land in unorganized parts were taxed, while land in organized regions escaped. He was strongly in favor of the 2c. tax, and thought there were even reasons for a higher tax, say of 5 or 25c. per acre. He spoke of the thousands of acres where the mineral rights had been bought by speculators, while the farmer who owned the land paid the taxes. In eastern Ontario there were places, owing to this anomaly, where it was practically impossible to obtain a title. The owners of the mining rights had disappeared. He said that the value of the minerals on the

property was evidently the only consideration actuating the owner, and if the owner desired to hold that land idle, he certainly should have no objection, for the privilege of doing so, to paying the people of the country five cents an acre, especially when the public was spending a considerable amount of money each year in assisting him to put his rights to a profitable account.

R. W. Brock, director of the Geological Survey, declared that the greatest bar to development was idle lands, tied up through being held by speculators and the title obscured. He deprecated the frequent practice of the past, by which mineral rights had been given away with the surface rights.

The subject was discussed by a number of speakers, Colonel Hay, of Toronto, advocating the appointment of a commission to secure uniform tax laws.

THE ELECTRIC FURNACE

The evening session was held at McGill University, and was devoted to an illustrated lecture by Professor Stansfield on "The Electric Furnace, with special reference to the Electric Metallurgy of Steel." By the aid of limelight illustrations, the various types of furnace were depicted, and interest centered strongly in the experiments in the melting of metal, etc.

At the close of the lecture a visit was paid to the basement rooms, where electric furnaces were shown in actual operation.

THE STUDY OF ORE DEPOSITS

At the morning session on Thursday, March 4, S. F. Emmons, United States Geological Survey, sketched the history and development of the present knowledge regarding ore deposits. He traced this from his experience of 40 years in the United States, and showed the present strong tendency to find that orebodies are principally connected with igneous and volcanic activity. Mr. Emmons laid particular stress on the benefits to the mining industry in the United States which had been derived from the careful study of its mineral deposits by the geological survey.

Waldemar Lindgren, United States Geological Survey, Washington, reviewed the distribution of mineral deposits in the United States and showed that rocks of different ages were characterized by minerals of distinctly different character. He distinguished these periods, marked by predominance of certain metals, as metallogenetic epochs.

Dr. A. C. Lane, State geologist of Michigan, gave an address on "Mine Waters of Michigan," presenting the results of an analysis of the waters and the deductions to be drawn of the nature and origin of the iron and copper ores. He also discussed the influence of the grain of rock and its value in determining the presence of copper and other ores.

EXECUTIVE SESSION

The afternoon session was an executive session, devoted to the consideration of proposed amendments to the by-laws. These were thoroughly discussed, and most of them adopted.

After the session a party of the members under the guidance of Prof. F. D. Adams, visited the buildings, museums and laboratories of the various departments of engineering at McGill University. The completed new building was pronounced by the visitors to be the finest of its class in America.

In the evening there was a "smoker" largely attended by the members and much enjoyed.

ASBESTOS AND CHROME ORE

The morning session on Friday, March 5, was largely taken up by an elaborate paper by John A. Dresser, mining geologist, of McGill University, on "Mineral Deposits of the Serpentine Belt of Southern Quebec," chiefly asbestos and chrome ore. Other minerals dealt with were talc, copper, antimony and nickel. He closed by laying stress on the view that the serpentine belt was not merely of present importance, but of still greater prospective value.

THE CLOSING SESSION

At the afternoon session a number of papers were read, among them "Notes on the Chibogomou Region of Quebec," by Prof. E. Delieux, of Laval University, Quebec; "Timber Resources in Mining Districts," by Dr. B. E. Fernow, Toronto University; "The Effect of Fungi on Mine Timbers," by James M. Macoun, Geological Survey, Ottawa; and "Notes on the Occurrence of the Orebody at the City of Cobalt Mine," by Dr. Frank D. Adams, of McGill. Other speakers were Dr. J. F. Kemp, of Columbia University, New York; and Fritz Cirkel, of Montreal, who read a paper on "The Depth of Asbestos Deposits."

The remaining business and the committee reports were then disposed of. At the close of the meeting President W. G. Miller, of Toronto, who presided, congratulated the mining institute on the large attendance, and the enthusiasm which the convention had evoked.

The meeting was closed by the annual dinner in the evening, which was largely attended. Among the speakers besides President W. G. Miller were the Governor-General of Canada; Hon. Mr. Templeman, Dominion minister of mines; Hon. Frank Dochrane, minister of mines of Ontario; J. Obalski, superintendent of mines of Quebec; G. S. Lindsay and Mr. Goodeve, of British Columbia; Dr. James F. Kemp, of New York; J. E. Hardman, of Montreal; George R. Smith, of Thetford Mines, Quebec, and others.

Personals

Mining and metallurgical engineers are invited to keep THE ENGINEERING AND MINING JOURNAL informed of their movements and appointments.

Dr. R. A. F. Penrose, Jr., has returned from Europe.

S. E. Bretherton has moved his office to 311 Mills building, San Francisco.

William H. Cook has moved his office from Tucson, Ariz., to El Paso, Texas.

E. S. Moulton, of Central City, Colo., is making a business visit to Eastern cities.

Leonard Lochr, manager of the King Solomon mine, Sylvanite, N. M., is in New York.

L. H. Jones, of Asheville, N. C., has been appointed receiver of the Franklin Kaolin Company.

Jules H. Hirt is now in charge of the Dos Cabezas mines, near Casas Grandes, Chihuahua, Mexico.

The office of Charles L. Denison, with the Buffalo Mines, Ltd., and the Morris Run Mines, is now at 165 Broadway, New York.

Robert Huntley is now president of the Bonanza Belt Copper Company, of Johnson, Ariz., in place of R. Allyn Lewis, resigned.

H. C. Vancil, formerly of Joplin, Mo., has taken charge of the Joplin Mining, Milling and Tunnel Company at Georgetown, Colorado.

E. E. Carter has been inspecting the Payette dam in Boise county, Idaho, with the view of installing power for the Gold Hill mine at Quartzburg.

David L. Gregg, long manager at El Paso, Tex., for the Mine and Smelter Supply Company, of Denver, has resigned and removed to California.

Stanley C. Sears has been appointed general superintendent of the Benito Juarez Mines Company, with office at Salinas, San Luis Potosi, Mexico.

Harrison S. Morris has been chosen president of the Wharton Steel Company, in place of the late Joseph Wharton. Mr. Morris has been treasurer of the company.

George A. Packard has returned to Wakefield, Mass., from a three-months' trip, in which he visited parts of Montana, California, Nevada, Texas and Mexico.

Herbert C. Hoover, who has been delivering a course of lectures at Columbia, sailed for London on March 10. He expects to visit this country again about the end of the year.

Dr. J. E. Woodman, professor of Geology at Dalhousie University, Halifax, N. S., has been appointed professor of geology and curator of the geological museum at New York University.

Claude T. Rice, recently on the staff of the JOURNAL, has accepted a position at

the Marmata mine on the Cauca river in Colombia. He sailed from New York March 6, on his way to South America.

Dr. Franz Meyer has resigned as director and treasurer of the Metallurgical Company of America and has returned to Germany to enter as partner in the firm of R. Wedekind & Co., at Uerdingen (Lower Rhine).

Millard Woodsome, treasurer of the Hoff Electrostatic Separator Company, is in Platteville, Wis., superintending some tests. He will return to Denver, Colo., shortly, where he will make his headquarters for some time.

Seward Babbitt, secretary and general manager of the Lash Steel Process Company and the Canadian Lash Steel Process Company, Ltd., has resigned his position with these companies and has returned to the International Steam Pump Company.

Henry M. Adkinson has undertaken the management of the Morning Star Mining Company for Boston clients who are operating near Ophir, Colo. Mr. Adkinson will continue as manager of the Gold Pioneer Mining Company at Telluride, Colorado.

Dr. Frank D. Adams, dean of the faculty of applied science of McGill University, Montreal, and Dr. Willet G. Miller, provincial geologist of Ontario, have been appointed honorary life members of the Institute of Mining and Metallurgy of Great Britain. Dr. J. B. Porter, of McGill University, and J. B. Tyrrell, of Toronto, have been elected to the council of the Institute.

William Morris Davis, professor of geology at Harvard University, who has been lecturing at the University of Berlin as exchange professor, is about to put in practice a plan unique in Germany. Accompanied by 60 of his geological students, he will make a tour through Sonderhausen, the Werra Valley, Göttingen, and the Leine Valley for the purpose of giving practical illustration to the subject of his lectures.

Frederick H. Morley has returned to Denver from Mexico, where he was during the past two months. As field engineer for the Potter Palmer estate of Chicago, he was engaged during January on the examination of the Promontorio mine at Cusihiuriachic, Chihuahua, which was taken over by the Palmer estate on Jan. 15. During the remainder of his stay he investigated mining properties in the States of Jalisco and Oaxaca for the Chicago Exploration Company.

H. S. Snyder, recently vice-president, has been elected president of the Juragua Iron Company, with office at South Bethlehem, Penn. DeBerniere Whitaker, recently general superintendent of the company, has been elected vice-president and general manager, with headquarters at Santiago de Cuba. E. M. Holmes, re-

cently assistant superintendent of the Spanish American Iron Company at Daiquiri, Cuba, has been appointed general superintendent of the Juragua Iron Company at Firmeza, Cuba.

Obituary

Dr. Gardner C. Wood, who died at Somers, Conn., March 7, aged 86 years, was for many years a student of geology, especially of the geology of the State. Some years ago he received considerable attention in connection with an alleged discovery of gold near his native place.

Societies and Technical Schools

Western Association of Technical Chemists and Metallurgists—The Chihuahua branch was organized at a meeting held Feb. 12. The following officers were chosen: Chairman, D. W. Shanks, La Plata mine; secretary, Leonard Worcester, Jr.; treasurer, George Griggs; member of board of control, J. H. Baron, Mexican Chemical Company.

Illinois Fuel Conference—A conference was to be held at the University of Illinois, at Urbana, Ill., March 11, 12 and 13, under direction of the United States Geological Survey, Technologic Branch; the Illinois Geological Survey and the College of Engineering of the University. The subjects to be considered included "Mine Explosions and Their Causes;" "Rescue Stations;" "Explosives;" "Coal Analysis;" "Smoke Suppression," and "Economy in the Use of Fuel." Examination of the fuel laboratories of the university, and of the mine explosion and rescue station recently established there were also on the program.

Mining Society of Nova Scotia—The seventeenth annual meeting was held at Halifax, March 3 and 4. The opening session was devoted to the president's address and the transaction of necessary business. Later Professor J. E. Woodman delivered an address on "Iron Mining in Nova Scotia," and a number of papers were read and discussed, among which were the following:

F. P. Ronnan—"A Practical Suggestion for Testing the Gold Mines of Nova Scotia."

E. Percy Brown—"How Can the Gold Mining Industry of Nova Scotia be Assisted?"

E. Percy Brown—"Conservation of Our Forests in Relation to Gold Mining."

C. V. Brennen—"Some Mining Conditions in Nova Scotia."

H. B. Pickings—"Gold Production in Nova Scotia from 1883 to 1908, inclusive."

H. E. Coll—"Shaft Collar at No. 1 Allan Shaft."

John Johnston—"Submarine Coal Mining."

News of the Industry Reported by Special Representatives at San Francisco, Butte, Salt Lake City, Denver, Toronto and Indianapolis

REVIEWS OF IMPORTANT EVENTS

San Francisco

March 6—The farmers in certain townships of Yuba county are protesting against the Government settling basin for débris established on the Yuba river south of the dredge at Hammonton. In the control of the river the engineers of the Federal Government decided on the construction of a series of restraining basins for the retention of coarser débris, the building of a series of training walls and a diversion canal connecting with a settling basin for the impounding of sand carried in suspension by the waters of the river. The protesting farmers assert that there is danger in the construction of such dams and basins because in flood seasons like the present, a mass of water may be suddenly released and overflow their properties. The settling basin is being built by the dredgers. These same people also protested against the proposition of the county supervisors to increase the number of pounds allowed to be hauled over the roads during the rainy seasons. At present the amount allowed is 3500 lb. and only last week a dozen teams were fined \$50 each for hauling loads on county roads exceeding this amount. The Marysville merchants want the present ordinance changed in the interest of the dredge mining people because they have large quantities of heavy freight delivered from Marysville to Hammonton where the large dredges are in operation. Some of the pieces of machinery manufactured in the new shops at Marysville, and intended for the dredges at Hammonton weigh thousands of pounds and must be hauled intact by large teams. It was asserted that the poor roads prevailing dated from the advent of the dredge interests in the county. The community in that section has not prepared itself for the beginning of large enterprises such as the manufacture and operation of dredges. For many years, since the virtual prohibition of hydraulic mining, most of the people have been engaged in farming pursuits. Now come the dredging interests with a large manufacturing establishment at Marysville and numerous dredges at Hammonton. The old-fashioned ideas of hauling loads of hay, etc., over the roads must in time give way to more modern methods where it is necessary to provide roads capable of standing the weights of heavy machinery. To all this the farmers protest but the dredge men have decided to force the issue since they cannot work satisfactorily under present conditions. The roads must

be rebuilt to suit present circumstances or these large enterprises will be greatly hampered.

The new rock-crushing plant of the Natomas Consolidated at Fair Oaks in the Folsom dredging field, now in course of construction will cost \$150,000 and produce 1500 tons of crushed rock every 10 hours. The rock will be crushed to seven sizes, including small gravel for roofing purposes. This new plant, together with the old one already in operation at Dredge, in the same field, will enable the company to ship 65 cars of rock every working day. Storage capacity is arranged for 125,000 tons so that after each winter large quantities of rock will be available for road work. All this rock comes from the cobbles dug out in dredge operations on the auriferous gravel. Good macadam is also being made from cobbles dug up by the dredges at Oroville in Butte county. This by-product of gold dredging is one of the things not at first thought of in connection with this industry.

The mine owners of the State are much interested in a bill which makes any person who purchases gold bars, bullion, gold quartz, or gold bullion or mineral containing gold, keep a register of the transaction with the name and residence of the pledger or seller. He must also produce for inspection this register to any officer holding a warrant authorizing him to search for personal property, or on the order of a committing magistrate directing such office to inspect said register, or account of sales or purchases. This is in the interest of mine owners who are losing money through "high-grading."

No less a person than the secretary of the Associated Oil Company, the largest State organization engaged in the production of petroleum, is of the opinion that there is now an overproduction of oil in California. He thinks that the overproduction will be between 6,000,000 to 9,000,000 bbl. per year. While there were 47,500,000 bbl. of oil produced in California in 1908, 53,000,000 to 56,000,000 bbl. will be produced this year. In January, 1909, the production was 146,000 bbl. daily against 142,000 in January, 1908. At present there are 450 strings of tools running in the State producing 900 wells annually, which wells are naturally yielding much oil. The first of this year the Associated Oil Company issued a general order to cut down on its development work for the present. The home consumption of oil is increasing, but oil men must look to the Far East to help use up the vast amount

now being produced in California. Japan is expected to be the principal foreign consumer.

Within a day of the time that the holders of the bond on the Oustomah gold mine at Nevada City intended to throw up the bond and quit, a clean-up at the mill proved that the ore was much richer than was expected, and 24 hours more time was asked for to make payment.

Salt Lake City

March 5—The International Smelting and Refining Company has three miles of grading completed and ties laid. The rails have arrived and the entire line will be finished by May 1. The railroads announce a reduction of \$1 per ton on ores ranging between \$20 and \$60, and 50c. per ton on ores ranging between \$70 and \$100 from southern Nevada camps to the Salt Lake valley smelters. This reduction commences on April 3, and will particularly affect Goldfield and Tonopah.

Nearly 400 stocks are now listed on the exchange and most of them are active. The recent strike of the Iron Blossom was responsible for heavy trading in Tintic stocks. The Iron Blossom has begun the stoping of ore, and 100 tons of high-grade ore will be shipped to the Knight smelter daily.

The following properties, all of which are situated at American Fork and are controlled by Jesse Knight, have been listed upon the local exchange. Each company has a capital of 1,000,000 shares of 10c. par value. The ores carry lead, silver, gold and copper. The Mineral Flat, comprising 25 claims; the Miller Hill, 23 claims; and the Major Evans Con., 31 claims. There are now 17 Knight companies listed upon the Salt Lake exchange.

The Grasselli zinc plant at Park City is now treating 65 tons of zinc middlings per day. At the annual meeting of the Bullion-Beck Company, held March 1, the following officers were elected: George W. Heintz, president; J. F. Smith, vice-president and treasurer; P. F. Farnsworth, J. A. Cunningham, C. E. Allen, J. Fawson Smith, Jr., and Frederick Lyon, directors. This property is now controlled by the U. S. Smelting and Refining Company.

The Cactus mill at Newhouse was closed March 1. It had been the intention to keep one-half of the mill running while the other half was being remodeled, but on account of the low price of copper it was deemed best to suspend operations entirely

while the mill is being remodeled. This work should be completed about the middle of April.

Butte

March 4—The affairs of the North Butte Extension Development Company, successor to the North Butte Extension Mining Company, are still far from settled. J. A. Ryan, superintendent, has recently resigned as a result of orders from the East to suspend all operations. A. M. Andrews and R. J. Horner, of the board of directors, have also resigned, and there is still considerable dissension among the stockholders as to the details of the reorganization plan. It was the intention of the management to commence operations within a short time, and the surface plant was put in readiness for this purpose, but the difficulties encountered within the past few weeks have delayed resumption of work. It is stated that trouble has been experienced in getting the stockholders of the old company to pay the assessment necessary to exchange the old stock for the new, and that until there is a more generous response to the company's offer of exchange there will be no further work done on the properties.

The Government assay office at Helena has made public its report for the month of February showing that the amount of bullion received exceeded that received in February, 1908, by \$32,821. The contributions from the several counties are as follows: Broadwater, \$2569; Chouteau, \$37,296; Deer Lodge, \$3807; Fergus, \$57,996; Granite, \$194; Jefferson, \$73; Lewis & Clark, \$9160; Madison, \$28,849; Missoula, \$400; Silver Bow, \$772.

Denver

March 6—At Leadville the Western Mining Company, working the Wolfstone mine, which has one of the deepest shafts in the northern part of Carbonate hill, has secured the adjacent territory extending as far north as Big Evans gulch. This territory is now to be developed by a tunnel driven from some point near the bottom of the Wolfstone shaft, which will pass from 300 to 500 ft. under the old workings in Small Hopes, Robert E. Lee, Tip Top and other bonanza mines. The purpose of the work is to develop the lower ore horizon of that section.

In the Cripple Creek district, the output for the past month was diminished by the bad weather. Operations at Stratton's Independence were retarded by the same causes, but now that spring has arrived, the mill has gone to work on the dump ores.

The Gilpin county camps of Central City and Black Hawk have not been materially affected by the severe weather. The Newhouse tunnel is being driven

ahead with a small force, with no new developments of note to record as yet.

The high mines of the San Juan region are still in the grasp of winter, and in fact mining operations all over the State are quiescent from similar reasons.

Goldfield, Nevada

March 2—Production of the Goldfield mines for the week ending Feb. 27 was 6595 tons valued at \$259,600. This does not include ore shipped to the Western Ore Purchasing Company.

The Nye and Ormsby county banks located at Reno, Carson City, Tonopah, Manhattan and Wonder closed their doors Feb. 23 and have gone into liquidation. The banks are entirely solvent and this action is due to the stringency of the money market, it being impossible to secure the necessary coin without sacrificing securities. The assets aggregate \$1,600,000 with only \$300,000 due its depositors, which insures every depositor being paid in full and that the stockholders will receive par for their stock, with a surplus left over.

In a decision rendered March 1 by the Supreme Court of Nevada, Thomas B. Rickey wins in the habeas corpus proceedings and all indictments against him and the bank directors fail. The court holds that under the State banking laws the receipt of funds by the teller could not be a receipt by the president unless an agency existed between them so the president could be regarded as principal. As an appeal to the U. S. Supreme Court is unlikely to be made, this means that Rickey and associates will go free after wrecking hundreds of homes in this State by their unsound financial exploitations.

At the Directors' meeting of the Florence Goldfield Mining Company held in Goldfield March 1 the entire board of directors was re-elected. It was decided not to pay a dividend at this time. This decision is explained by the fact that most of the leases heretofore existent, have expired and with them a large source of revenue has been cut off. No specified time is set for the resumption of dividends but they will be declared as soon as financial conditions warrant it.

Indianapolis

March 8—The order appointing William C. Niblack, of Chicago, receiver for the Deering Coal Company was brought to this city during the past week for entry in the United States Court. The managers of the company mines in Indiana say it has been evident for some time that big customers of the Deering mines were going elsewhere. The Illinois Steel Company transferred contracts for several thousand tons daily to other Indiana companies, notably the Vandalia Coal Company.

Some of the orders went to companies in the Clinton field. Coincident with these transfers has been great activity in securing coal-land options in the Clinton field and also in the Vigo county field, which, too, is coincident with the recent incorporation of a company to build a short line from that particular field into Illinois by which coal may find outlet to the big steel plants on the lake near Chicago.

The Deering company was one of the first Western coal-mining companies to form a big merger and placed over 30 mines in this State under one management. The company owns about 17,000 acres of coal land in Indiana, and an effort will be made to keep the mines running under the supervision of a receiver to be named in Indiana. The March pay-roll will amount to \$150,000. The Deering company was incorporated under the laws of Delaware in 1904. Its general offices are at 84 Van Buren street, Chicago. R. R. Hammond is president and J. B. Boynton secretary.

The Indiana Legislature adjourned March 8 after a 60-days' session. A number of bills affecting mines and miners were introduced, but only a few were enacted into law. The Foor bill providing for weekly payment of wages to coal miners, and the Higgins bill, making it lawful to use mine drills 3/4 in. in diameter and requiring the operators to sharpen them, were passed.

An appropriation of \$7500 was made for the expense of the State Mine Inspection Department, and \$8420 for the Department of Geology. Special efforts are to be made for the betterment of mining conditions and for the completion of coal-land surveys during the next two years.

Toronto

March 6—An order in council just adopted by the Canadian government extends the regulations for the disposal of quartz mining claims to lands within the limits of reserves established under the Dominion Forest Reserves act subject to the following restrictions: A crown grant will not be issued but the holder of a claim may obtain a 21-years' lease; no trees are to be cut without the permission of the Superintendent of Forestry; the lessee must keep clear of all inflammable material a space of at least 100 ft. from his works; engines must be fitted with spark arresters. The regulations in regard to coal-mining rights in the Northwest have been changed. Heretofore such rights could only be obtained by lease, the lessee paying in advance \$1 per acre yearly. By the new regulation an applicant may obtain a two-years' lease of 2500 acres on payment of \$100. This is designed to encourage prospecting for coal where no known surface indications exist. The money will be returned upon proof of actual prospecting work having been done, or will be applied on rental in case of subsequent lease.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Arizona

COCHISE COUNTY

Swisshelm—Prospecting is being carried on in the Swisshelm mountains across the Sulphur Springs valley from the new camp of Courtland. The Swisshelm Development Company and the Heffern Mining Company are each sinking shafts. Gold-copper ores have been found in the shafts of both companies.

GRAHAM COUNTY

Shannon Copper Company—Plans are being made to increase the output to about 2,000,000 lb. a month in order to reduce the cost of production.

GILA COUNTY

New York-Arizona Gold and Copper Company—Development work on the Louise claim has been rewarded by the disclosure of an 8-in. vein of gold-copper-silver ore at the 80-ft. level. A 15-h.p. gasoline hoist has been installed at the shaft, but work has been discontinued on account of water. Close to this shaft, the Thompson tunnel, which has been driven about 400 ft., opens up a 4-ft. vein of gold-bearing rock.

NAVAJO COUNTY

Silver Creek—A new company has been organized under the name of the Portal Mining Company to operate the Duffner property.

California

AMADOR COUNTY

Defender—Owing to the difficulty of obtaining fuel, this company has shut down for the present.

Zeila—Underground men have been laid off because of the immense flow of water at present.

BUTTE COUNTY

Wyandotte—The mill has been rebuilt, equipped with a new power plant and has commenced crushing ore from the mine of the company.

Mammoth Channel—At this property, Magalia, a new engine and hoist have been installed and the shaft is being enlarged. Funds are in hand to carry on the work of more effective prospecting of the channel.

CALAVERAS COUNTY

Black Metal—The new hoist has been completed, to be run by water power.

The mine is being worked through an incline.

EL DORADO COUNTY

Union—This mine, near El Dorado, now has 73 men on the pay roll and 20 stamps of the mill are running. Twenty more will soon start. Large quantities of sulphurets are being shipped. It is expected that the mine will be provided with 100 stamps during this summer.

INYO COUNTY

Lost Burro—This group in Ubehebe district has been investigated by Los Angeles men with a view to purchase for \$60,000. There are six claims in the group.

MONTEREY COUNTY

Chualar Cañon—A company is about to be organized to develop mines in Chualar cañon. Geo. V. Barlow and O. Hallett are the principal owners.

Cruikshank—It is reported that a rich strike has occurred in this old mine in Los Burros district. This was the first mine to be exploited in that district and at one time very high-grade ore was taken out. Labor is somewhat scarce in that section.

NEVADA COUNTY

Lecompton and Norambagua—These two mines have been separately incorporated with the following directors: A. Gilbert, Santa Barbara, H. S. Abbott, Nevada City; H. K. Gilbert, Chicago; J. C. Anderson, New York; W. G. Griffith, Santa Barbara, Cal. The Lecompton is near Nevada City and the Norambagua near Grass Valley. They are both under bond to H. K. Gilbert, of Santa Barbara. The Norambagua is being worked and the Lecompton will soon be pumped out and developed.

Pittsburg-Gold Flat-Potosi—A new company, Mark B. Kerr, general manager, will retimber the Pittsburg shaft to the drain tunnel and the drain tunnel will be put in order. After a survey is made it will be determined whether to operate through the old shaft or sink a central shaft to develop the three properties under control of the company.

SAN BERNARDINO COUNTY

The camps on each side of the Ivanpah valley, which is crossed by the Salt Lake railroad between Cima and Goodsprings, are prosperous at present, numerous discoveries having been made.

These are Kewahnee, Ivanpah, Clark, Goodsprings, Keystone, Lyons, Crescent, Vanderbilt, New York and Death Valley districts.

SHASTA COUNTY

Shasta Gold Belt Mining Company—This organization owns mines six miles west of Redding and is doing considerable development work. Machinery is also being put up. A. L. Nichols is superintendent.

Conner—The group of mines owned by E. P. Conner & Sons on Salt creek, near Middle Creek station, has been bonded to New York men represented by M. T. Whitlock, of Kennett. There are both gold and copper claims on which work will be commenced shortly.

SIERRA COUNTY

Gray Eagle—At this mine, Gold Point, W. L. Turner, superintendent, a number of improvements are being made and 10 more stamps will soon be added to the present 30-stamp mill.

Sierra Buttes Mining Company—The old No. 6 tunnel at Sierra City is being reopened and retimbered in order to mine ore which the English company is supposed to have left.

Alaska Mining Company—The station at the 500 level has been timbered and the work of sinking is being continued. The bottom of the old works has been reached.

Jersey—This group, between Omega and Kanaka creek, has been sold by C. C. Slattery and the new owner will at once extend the 1500-ft. tunnel to tap the channel.

SISKIYOU COUNTY

Scott Bar—The company, which has been digging ditches for the past six months, is to build another three-mile ditch to tap Kelsey creek; and a four-mile ditch up into the cañon to tap Scott river. They are preparing to pipe the high channels near Scott Bar.

TRINITY COUNTY

Trinity River Tunnel Company—The 1450-ft. tunnel through Horseshoe bend near Lewiston, lacks only about 100 ft. of completion, and will be finished shortly. The tunnel is expected to carry the entire flow of the river for nine months each year, during which the bed at Horseshoe bend may be mined.

West Point—This company, which has under bond the Leas & Nicholson group at Deadwood, adjoining the Brown Bear group, is running a lower tunnel to tap the vein.

TUOLUMNE COUNTY

New Albany—A strike of exceptionally rich ore has been made while stoping on the 300 level.

Karnac—This company has obtained possession of the Hancock quartz mine four miles west of Rawhide. The company has also an option on the Sarah Marble claims, owned by the Barnard Brothers.

United Mines Corporation—This company has 100 men taking out ore from East lode properties. These are the Grizzly, New Albany, Lady Washington and Head Horse. Good ore is being taken from the New Albany.

Colorado

BOULDER COUNTY

Pittsburg & Gold Hill M. Company—W. R. Crockett, of Boulder, has faken the contract for the erection of a 15-stamp concentrating mill on the company's property at Rowena, and a half mile tramway is to be built to connect mine and mill.

Smoky Hill—A. Berger and associates, of Denver, have opened up good ores and are arranging for the installation of a compressor plant at Sugar Load mountain.

Black Swan—O. H. Brown & Co., Denver, have purchased the mill and will remodel it from a stamp mill to a modern cyanide plant for the purpose of handling custom ores as the product of the Sunshine mine near Salina.

CLEAR CREEK COUNTY

Geneva Extension, M. M. T. & C. Company—Eastern people have become interested in Peru district and E. K. Cass, of Georgetown, Colo., is in charge of operations.

Kennedy Mining Company—Boston capitalists are interested in subscribing a large sum of money for the development of the Centennial property near Georgetown.

Griffith—A new company is being formed with W. D. Hoover, Georgetown, Colo., as manager. The company will erect an electro-chemical milling plant of fifty tons capacity for the treatment of its ores.

Philadelphia, M. & T. Company—Philadelphians are interested in the purchase of a group of claims at Kelso mountain, formerly owned by J. T. Hamill. Their office is at Georgetown, Colo.

Magnet—This group on Saxon mountain has been bonded by G. Laughlin, of Chicago, Ill., the bond calling for \$80,000 of which a cash payment of \$20,000 has been made.

GILPIN COUNTY

King Bee, G. M. Company—A good strike is reported on the Wellington No. 6 vein of this company, in lateral workings of the Newhouse tunnel and at a depth of more than 1700 ft. R. L. Martin, Quincy building, Denver, Colo., is manager.

Great Bonanza, G. M. & M. Company, Ltd.—British capital is interested and they have commenced developments on their Next President group of claims and are overhauling their Eagle amalgamating and concentrating mill at Black Hawk. C. C. Morgan, Central City, Colo., is manager and it is reported that the company will install the Elmore oil process.

Concrete Group—Edgar S. Moulton, of Central City, Colo., has purchased the mine from the Rocky Mountain National bank. Mr. Moulton has been operating it under lease since last June. Arrangements are being made for the deeper workings.

Sherman & Macoon, M. & M. Company—A good strike is reported in the main tunnel. F. L. Branham, Central City, Colo., is superintendent.

Hawn—Boulder people have purchased the property in Moon gulch and are preparing to develop it on a liberal scale. It is situated near the Smuggler.

Rocky Mountain Concentrator—Edgar S. Moulton, of Central City, will remodel the plant in Black Hawk, and will install new stamps, jigs and other machinery, increasing its capacity.

LAKE COUNTY—LEADVILLE

Bartlett Tunnel—Under the new management this property, Sugar Loaf district, will be extensively worked. While the tunnel was being driven several veins were cut, all showing ore, and it is the intention of the management to develop them thoroughly. The Bartlett vein will also be worked, and the tunnel driven ahead to catch the northern extension of the Dinero.

Iowa Gulch—Lessees have been at work during the winter on the Ella Beeler and Little Alice, also the Houston, and now have 200 tons of high grade ready to ship as soon as the roads are opened. The principal work has been done through a tunnel driven to the Houston and at this property rich gold ore was caught. The streak is small, but rich. Work has been done on the other claims and high-grade ore found. The three claims are on the same ore belt as the Lillian.

Margaret—In this mine, Granite, in the east drift at the 80-ft. level a few days ago a 3-in. vein of jasper was opened, with free gold. In addition to the rich streak there is a 2½-ft. vein of good milling ore.

Pycnnes—Lessees are driving a drift from the 1000-ft. level, Graham park, to connect with the R. A. M. When this is

done extensive operations will be carried on in both properties. When the connection is made all of the hoisting will be done from the R. A. M. shaft.

Sunday Vein—Since the opening of this vein by the tunnel, the width being 12 ft. from wall to wall, the general opinion of mining men is that the vein will carry as far south as Empire gulch, and several will back this opinion up by driving tunnels on intervening ground. This work will be started early next month.

TELLER COUNTY—CRIPPLE CREEK

Callie—Work will soon be commenced in building a new ore house at this shaft. Some time ago some ore was found in the property, but at present no work is being done, as there is no way of disposing of the ore until the new ore house is built. The property belongs to the Stratton estate and is being worked under lease by the Callie Leasing Company, of which H. D. Thompson, of Cripple Creek, is the manager.

Victor—A considerable part of this property which is under lease to the Roscoe Leasing Company, is being worked under subleases. The property is situated on Bull hill and was one of the first shippers in the district. A large amount of ore has been shipped in the past and the company has paid more than its capitalization in dividends. Until recently for a number of years but little has been done on it. The property is owned by the Victor Gold Mining Company, of which D. H. Moffat, of Denver, has the control.

Illinois

Deering Coal Company—The United States Circuit Court at Chicago on March 4 appointed William C. Niblack receiver of the property upon application of creditors and stockholders. It is declared that the company is being pressed by creditors to whom it owes \$1,000,000, and that it will be unable to meet the interest on its bonded debt (\$5,000,000 first mortgage 5%, of which at last accounts \$550,000 were in the treasury and \$324,000 in sinking fund; also \$9,000 Wilfred Coal Company first mortgage gold 5%). The company, it is alleged, has year contracts with the Illinois Steel Company, the American Steel and Wire Company, the American Bridge Company, and the American Tin Plate Company, to furnish annually from 900,000 to 2,000,000 tons of coal, but is unable to collect \$215,000 due from these companies because of damage claims which the Deering company alleges to be without basis. The property includes a number of mines in Illinois and Indiana.

Kentucky

Bell-Jellico Coal Company—A controlling interest has been sold to A. S. Braznell, of

Pittsburg, and associates. The company owns the largest operating mines in the Jellico district.

Michigan

COPPER

Arcadian—At the recent meeting of this company it was decided to sell its lands in Section 16 and also the main property to a new company which will soon be organized under the laws of Michigan, and which will in all probability take adjoining lands and begin operations on the northern extension of the Baltic lode.

Calumet & Hecla—This company continues exploratory work on the White Pine property in Ontonagon county. Trenching is going on with encouraging results.

Cliff—This company is carrying on diamond-drill operations close to the northern boundary of the Ojibway property, in view of opening the Kearsarge lode.

Michigan—A much better showing is being made at the A shaft, near the 17th level. The Calico lode is being opened by crosscuts. The shaft is on the hanging wall side about 75 ft. from the formation. Exploratory work has been started on some old workings lying in the eastern part of the property.

Copper Range—A much better grade of mineralization is being revealed in the lower workings of the Trimountain property at No. 4 shaft. Below the 13th level is an exceptional showing of good stamp and mass copper. At No. 2 shaft drifts on the 14th level are entering better ground.

Keweenaw—Sinking continues in the Medora shaft below the 16th level. At the 13th level a drift is being extended to the north to intercept the fissure vein that was exposed at the 11th level, and which promises to become an important factor in this company's development. Rock shipments aggregating about 110 tons daily are being made to the Phoenix mill.

Ojibway—At No. 1 shaft the crosscut from the 660-ft. level has entered the west bed of the Kearsarge lode and the mineralization exposed is even richer than opened at the level above. This bed is separated from the first, or east bed, by about 20 ft. of trap rock. At No. 2 shaft the crosscut from this same depth is in about 50 ft. on its way to cut the formation and has about 30 ft. more to go.

Superior—The 7th mill run put through the Atlantic mill yielded about 70 lb. of mineral to the ton of rock stamped, making about 50 lb. of ingot copper. This remarkable showing was made from the rock coming principally from the lower openings and a small portion from the stock pile.

Arcadian—Plans are being formulated

for the organization of a new company to assume control of the Arcadian. The new company will be organized under Michigan laws and will have a capitalization of 150,000 shares, par value \$25. Holders of Arcadian stock will be given share per share, but as the new company's stock will be assessable. Funds will be provided in this way for the development of the property. The sale of lands in section 16 to the New Baltic Exploration Company will give the company sufficient funds to resume operations without calling an immediate assessment. The Arcadian has a complete exploratory outfit and a shaft down about 200 ft. in close proximity to the trend of the formation recently opened at the New Baltic.

New Baltic Exploration—Trenching continues at this property and some very fine specimens of copper-bearing rock have been revealed, showing all the characteristics of the Baltic lode, and it is believed by the management to be the northern extension of this formation.

Missouri

JOPLIN ZINC-LEAD DISTRICT

Old Dominion—Six men were killed in a cave-in at the Buxton & Owens mine. The old Dominion has purchased 80 acres in Gordon hollow for \$30,000.

Live Oak—The mill belonging to Husman Brothers, of Joplin, has been destroyed by fire.

Carnation—A rotary crusher is being installed to take the place of the regulation Blake crusher and rolls.

Lockport Mining Company—Short creek bottoms at Galena have been successfully drained and 16 lessees are already at work.

Montana

BUTTE DISTRICT

Amalgamated—The Little Mina mine of the Parrot company is fast proving to be the big producer of that company. The shaft is nearly 1200 ft. deep. The principal development work is being done on the 600-, 800- and 1000-ft. levels. On the 1000-ft. level the vein south of the shaft has been opened up a distance of more than 700 ft. An auxiliary engine is being used for sinking the shaft, but plans are being made for the installation of a new hoisting engine, good for 2000 ft. The Parrot shaft is down 2000 ft., and work is being done on the 1200, 1400, 1600, 1700 and 1800 levels. On March 3, at the Diamond mine of the Anaconda company, a premature blast in the sump caused the death of four men working in the shaft. The shaft is now down 2500 ft., and sinking is still in progress.

Butte-Milwaukee—A deed has been recently filed for record conveying from the John Caplice Company to the Butte-Mil-

waukee Company an undivided three-fourths interest in the Bird quartz lode mining claim.

Butte-Knickerbocker—At the recent annual meeting of stockholders the following were elected directors for the ensuing year: George H. Roberts, of Boise, Idaho; F. L. Cobb and Edwin Higgins, of New York; B. F. White, of Dillon, Mont.; James Davidson, William Dyer, E. E. Kinerk, J. F. Saville, T. W. Bradley, J. M. Montgomery and George B. Conway, of Butte. Of these G. B. Conway was elected president; James Davidson, vice-president; B. F. White, treasurer; and William Dyer, secretary. The company's property is situated in the district immediately north of Butte.

East Butte—A vein carrying commercial ore has been recently encountered in the crosscut on the 900-ft. level south of the shaft. Drifting has been done for a distance of about 25 ft., and the management states that the vein shows a width of 7 ft. and an average assay of 9 per cent. copper and 20 oz. silver per ton.

Butte-Montana—A special meeting of stockholders has been called for March 20 to consider the plan to sell the company's property to the Butte-Alex Scott Company. Thomas A. Merritt, of Duluth, representing the Alex Scott Company, has submitted the plan that the old stockholders be given the opportunity of subscribing to the new company's stock on the basis of one share of the new for 10 shares of the old and a payment of \$2.

JEFFERSON COUNTY

Comet Mine—This property has been closed down indefinitely. For the past six months the pumps have been kept in operation, but it has been several months since any development work has been done.

MISSOULA COUNTY

Iron Mountain Tunnel Company—This property, valuable principally as a silver-lead producer, is situated at Carter, Mont. A shaft has been sunk from the top of a mountain to a depth of 1700 ft. This connects with a tunnel one mile in length, driven in the side of the mountain. Work has recently been resumed and a new compressor and hoist are being installed.

POWELL COUNTY

Butte & Elliston—The company's properties are six miles from Elliston. About 20 men are now employed. Two carloads of ore were shipped during the last 30 days to the Pan Handle Smelter in Idaho. The management states that the net smelter return on ore shipped was \$900 per car. The ore carries gold, silver and lead.

Nevada

CHURCHILL COUNTY—FAIRVIEW

Nevada Hills—The station recently cut on the 350-ft. level is in a high-grade ore,

the principal value being gold with some ruby silver. The orebody, as found on the 200-ft. level had a pitch to the south, and contained silver alone. It was intercepted by a quartz dike, and at the 300-ft. level the ore now occurs beneath the dike.

Nevada Hills—The strike recently made on the 350-ft. level of this property has improved much with development and the orebody shows a width of 6 ft. which assays from \$30 to \$40 per ton gold and silver in the proportion of 3 to 2.

CHURCHILL COUNTY—WONDER

Nevada Wonder—A ten-stamp mill is to be erected on this property. Francis L. Bosqui, the engineer who planned the system of ore treatment for the Goldfield Consolidated has made preliminary tests that warrant a satisfactory recovery from the ore.

Nevada Wonder—It is reported that the Nevada Wonder will erect a mill on its property, which report is strengthened by the fact that engineers have been making extensive surface surveys recently.

Wonder Venture—The directors of this company have issued a circular letter to the stockholders asking for contributions amounting to $\frac{1}{16}$ per share to take care of a judgment and a number of small outstanding bills.

ESMERALDA COUNTY—GOLDFIELD

Phonolite Paymaster Mining Company—About 1000 feet of tunnel and shaft work has been done at a cost of \$10 per foot. The miners have taken their pay in treasury stock at 25¢ per share. The property is located near Phonolite, Nev.

Gold Bar—A good grade of ore is being taken out above the 200-ft. level; and also from the 300-ft. level. Development work is being carried on at the same time.

Consolidated Red Top Lease—A 4-ft. vein of ore has been opened up in the new stope above the 300-ft. level; the ore is farther south than in the old ore shoot, and toward the Red Top workings, which are being worked by the Consolidated Mines Company.

Black Eagle—The shaft, which is down 100 ft., will be pushed to the 150-ft. level when laterals will be extended across the formation. The property is 8 miles northeast of Goldfield.

Kansas City Velvet Lease—Small shipments are being made from this property, the ore being extracted at a shallow depth. The main shaft is 300 ft. deep.

Goldfield Consolidated—At a meeting of the directors held in Washington, D. C., Feb. 25, a dividend of 30¢ per share was declared, payable April 30 to stockholders of record March 31. This amounts to \$1,080,000 and leaves over \$1,000,000 in the treasury.

Little Florence—Ore of a low grade has been encountered on the 350- and 500 ft. levels of this property. The ore is identi-

cal in character with the high grade from other properties.

HUMBOLDT COUNTY—SEVEN TROUGHS

Reagan Lease—Development work shows better ore on the 300-ft. level.

A rich strike has been made in the north drift of the 300-ft. level where milling ore 3 ft. wide is showing with a narrow high-grade streak of shipping ore. The ore shoot is thought to be a continuation of the ore exposed in the 165-ft. level from which one carload sent to the smelter returned \$1030 per ton.

NYE COUNTY—BULLFROG

Pioneer Lease—The crosscut on the 210-ft. level intercepted an orebody Feb. 21, and has penetrated the same 15 ft. without reaching the hanging wall. The ore has been sacked as broken down and stored in the mine pending the construction of larger ore bins. A shipment of two carloads was made Feb. 28.

Pioneer Extension—A contract has been let for 100 ft. of sinking; the shaft is to be double compartment 4x8 ft. in the clear.

Notional Bank—Settlements for the last shipment from the Logland lease, to the smelter at Needles, show three tons yielding \$493 per ton, and 34½ tons \$58 per ton.

Tramps—The main tunnel is now in 1400 ft. A hoist has been installed near the face and a winze sunk 100 ft., from the bottom of which a crosscut was run to cut the Tramp vein. This vein has now been penetrated and shows 12 ft. of milling ore.

NYE COUNTY—ROUND MOUNTAIN

Valley View—An important ore discovery was recently made in the incline. The vein varies from one to five feet in thickness and assays \$20 to \$25 per ton. The vein is pure white quartz and is different from anything heretofore found in the district.

Jefferson Mining Company—James MacDonald has been engaged as manager. The old workings of the Kanrohat property will be thoroughly prospected before any new development work is carried on.

NYE COUNTY—TONOPAH

Midway—Prospecting for new orebodies is being extensively carried on in the second, third, fourth and sixth levels, with stoping on the third and fourth levels.

Belmont—The most noteworthy feature shown by the past week's development is the increased size of the orebody exposed in the east drift from a winze sunk from the 1000-ft. level, which now varies from six to seven feet, carrying a good grade of ore. Stoping is being carried up from the 1100-ft. level; in two places the backs being 20 ft. and 60 ft., with 125 ft. between.

Tonopah Extension—General Manager Kirchen has just returned from attendance at the directors' meeting in New York City and states that a 30-stamp mill will be constructed within the next few months.

NYE COUNTY—HELENA

Broken Hills—Reports from this property indicate satisfactory results from development work. In the main workings the company has encountered a body of high-grade ore of the same character as that previously shipped; 2000 sacks are piled on the dumps and shipments are made at the rate of 15 tons per day, the ore running between \$140 and \$150 per ton.

New Mexico

GRANT COUNTY—SYLVANITE

Men from Cripple Creek, Colo., have obtained an option on three of the first claims staked in the camp, the Broken Jug, Golden Eagle, and Wake-up Charley. A cash consideration was paid for the option, which extends until March 1, and which gives the purchasing parties the privilege of buying a controlling interest, or nearly 60 per cent. of the stock in all three of the claims. The owners of the properties are, C. F., J. N. and E. J. Clark, who were the original locators, together with W. M. Carlin, Marvin Ish, Sol Camp and J. T. Goshen, holding altogether 700,000 shares of the stock, the other 300,000 remaining in the treasury. If the property is taken, work will be commenced at once upon a new shaft, probably near the line of the Broken Jug and Golden Eagle, and work prosecuted without any delay, modern machinery installed, and as many men put to work as can conveniently be handled.

SIERRA COUNTY

Monarch—The company is making extensive improvements in its plant. A large settling pond has been built, the water from which will be pumped back over the jigs and tables. The coarsest material is to be separated in jigs, while the slimes are treated on tables, the lead being saved by the first set and the zinc on the second, the contract being that the plant shall make a product having not to exceed 2 per cent. zinc in the lead concentrates and 1 per cent. lead in the zinc concentrates and not more than 10 per cent. of total loss in the tailings. The Galena Iron Works, of Galena, Ill., is remodeling the mill.

SOCORRO COUNTY

Tri-Bulion Smelting and Development Company—The mines are now producing and shipping smelting ore at the rate of about 100 tons a day, the ore being essentially zinc-bearing, but containing a small quantity of copper. The company intends to proceed with the construction of a smelting plant at Canon City, Colo., at an early date.

Oregon

BAKER COUNTY

Intermountain Mining Company, Ltd.—W. L. Vinson, the former owner of the mine, has transferred the control to the new company, with headquarters in Baker City. The group of 16 mining claims is 18 miles southeast of Durkee, in Baker county. Tunnel No. 3 is now in the mountain about 600 ft, with a depth of 300 ft. below the apex. Tunnel No. 2, just above tunnel No. 3, cuts the orebody 100 ft. below the surface. This vein is from 3 to 6 ft. in width. A winze started down in tunnel No. 2 shows that the orebody is widening as depth is attained. There are several veins of ore on this group of claims, all showing pay ore on the surface. The ore is free milling and is easily saved on the plates. There is a 20-stamp mill on the property with a capacity of 60 to 75 tons per day. The company has water right sufficient to run 1000 stamps and owns 240 acres of good timber land, situated $4\frac{1}{2}$ miles from the mine. The officers are M. S. Bond, president; Thomas Proffitt, vice-president; W. J. Patterson, secretary and treasurer; John H. Washburn, general superintendent.

The Irondyke—In the extreme eastern portion of Baker county there is some activity in the copper-mining industry. The Irondyke is owned by capitalists of Erie, Penn., and is managed by Frank E. Pearce, with headquarters at Homestead. One shaft is down about 700 ft. There are numerous tunnels, crosscuts, upraises and drifts amounting to about a mile of underground workings. The Irondyke is one of the best equipped copper mines in Oregon. The property is 60 miles from the railroad.

Peacock—Mr. Boggs, the manager and lessee, announces that as soon as the railroad is finished to Homestead, he will build an aerial tramway from the mine, across the river, to the O. R. & N. docks.

Sumpter District—The Columbia, Old Redboy, and the Imperial are operating with a full force of men. The Redboy is furnished with light and electric power from the recently installed Olive Lake Power Company.

Virtue Mine—This is an old mine and is under the management of J. K. Romig, of Baker City. It is operated by electric power, and is lighted throughout by electricity.

Uncle Dan—A few miles beyond the Virtue is the Uncle Dan mine, under the management of C. S. Blackmon, who is also the principal owner of the property. He is sinking the shaft down to the 300-ft. level. The mine is also operated and lighted by electricity.

GRANT COUNTY

Standard Mine—The Susanville district is 60 miles west of Baker City; the

Standard mine is operating in a small way, and has what is considered the only paying deposit of cobalt ore in the northwest.

Pennsylvania

BITUMINOUS COAL

Monongahela River Consolidated—The results of operations for the first quarter of the fiscal year—Nov. 1-Jan. 31—are reported as follows:

	1908.	1909.	Changes.
Net earnings..	\$ 680,254	\$ 195,970 D.	\$ 484,284
Charges	478,323	384,191 D.	94,132
Surplus.....	\$ 201,931	D. \$ 188,221	

Charges this year were made up as follows: Depreciation fund on coal mined, \$78,148; depreciation of equipment, \$105,002; taxes and insurance, \$78,751; interest, \$122,290.

South Dakota

CUSTER COUNTY

Hartwell—President Hart, of Chicago, is directing the work in the main tunnel, now in 345 ft., and will soon start drifting on the ledge.

Saginaw—The mill is dropping ten stamps regularly and making good monthly cleanups. The vein where the main work is done averages 8 ft. thick.

LAWRENCE COUNTY

Eskimo—The Regan brothers, of Lead, report a good strike on their Yellow creek property. A vertical ledge has been opened up that appears to be permanent.

Homestake—Sinking has been resumed in the Ellison shaft at Lead. This shaft is down 1700 ft., being the deepest one in the district. At Nemo the company is commencing a small shaft on a copper ledge that has just been found.

PENNINGTON COUNTY

Forest City—It is reported that the main ledge, which was lost in a fault some years ago, when the Clara Belle company operated the mine, has been found and is now being opened up at Oreville. It is 8 ft. wide.

Utah

BEAVER COUNTY

The Frisco Consolidated Mining Company—This is a new company formed with a capital of 1,500,000 shares, par value \$10 each. Malcolm, Green & Co., of Boston, have underwritten 17,000 shares at \$2 per share; 25,000 shares will be placed in the treasury. The Frisco Contact Company receives 103,750 shares; the North Horn Silver Company, 1000 shares and \$7000; the Glorious Company, 3240 shares and \$2500, and the Good Hope Company,

\$2000. The consolidated company has 31 claims and the property is considered one of the best in the district. It is equipped with a good hoist, compressor and pumping machinery.

The Lady Bryan—C. T. Birchard, of Boston, has purchased five claims in the Star camp just south of the Hub. In former years the property produced rich ore.

The Leonora—The main tunnel is now in 155 ft. and shows some ore in the face. The property adjoins the Red Warrior.

MILLARD COUNTY

Millard Iron Mining Company—A quartz vein carrying gold and silver has been encountered in the shaft at a depth of 45 feet.

North Billy—Surface development has exposed gold-bearing rock.

SALT LAKE COUNTY

Cardiff—Connection between the old and new workings and drain tunnel has been made. This will give a stoping back of 100 feet.

TOOELE COUNTY

The Lion Hill—Good ore has been encountered at the bottom of a Winze sunk from the tunnel level. The vein is 7 ft. wide and contains from 8 to 10 per cent. lead, with silver and some gold.

UTAH COUNTY

Dutchman Company—Four feet of lead carbonate ore has been cut about 100 ft. from the surface.

Canada

ALBERTA

The report of the Minister of Public Works for the Province of Alberta, recently submitted to the provincial legislature, states that in 1908 a total of 2,036,308 tons of coal was produced by 112 mines in the Province. The number of men employed was about 3500, and their wages ranged from \$75 to \$180 per month. During the year there were 62 coal-mine accidents, 17 of which were fatal.

As the existing agreement between the coal-mine operators and the men will shortly terminate, a joint meeting of representatives of the Operators' Association and the United Mine Workers of America has been called for the first week in March, to formulate a new agreement. For some time past reports have been in circulation to the effect that there will be a general cessation of work by the men until such time as they shall obtain more favorable terms, but this is denied by prominent officials of the local district who hold the view that "there is no likelihood of a shut-down, and that the adoption of such a course by either operators or men "would be suicidal."

South Alberta Irrigation Company—At Bow island this company has struck, at a depth of less than 2000 ft., a pressure of natural gas stated to be equal to about 7,000,000 cu.ft. per day. This flow is much greater than that met with earlier in the "Old Glory" well at Medicine Hat, where the flow is placed at about 4,500,000 cu.ft. per day.

West Canadian Collieries, Ltd.—During the latter part of February this company has been sending out from its Bellevue colliery 1200 to 1300 tons of coal per day, and on one day made its record output of 1350 tons. The company owns several collieries in the Blairmore-Frank district, and has its head quarters in the province at Blairmore. C. L. Rameau is general manager.

Scranton Coal Mining Company—This company has acquired the adjoining property, heretofore owned by the Central Mining Company. The combined holdings include 1500 acres of land. It is proposed to increase the output to 1000 tons of coal daily. S. Tanner, Spokane, Wash., is secretary and treasurer.

BRITISH COLUMBIA—ROSSLAND

Cabled advices from London state that the Le Roi No. 2, Ltd., which company has its headquarters in that city, has declared a dividend of 2s. per share, payable March 11. The authorized capital of this company is £600,000 in 120,000 shares of £5 each. Its output of shipping ore last year was about 30,000 tons averaging rather less than 1 oz. gold, 1 oz. silver per ton, and 1.6 per cent. copper. Its second-class ore, which is concentrated at the mines, runs about \$3.50 per ton in all values. Paul S. Coudrey, of Rossland, is general manager.

BRITISH COLUMBIA—NELSON

The president of the Associated Boards of Trade of Eastern British Columbia, in his report to the annual convention of delegates gave the following table showing the production of minerals and lumber in Southern Kootenay and Southern Yale during 1908:

Gold, 252,000 oz. at \$20.67.....	\$5,208,840
Silver, 2,988,000 oz. at \$56.....	1,673,400
Lead, 21,583 tons at \$70.....	1,510,810
Zinc, 10,000 tons at \$10.....	100,000
Coal, 582,000 tons at \$3.50.....	2,037,000
Coke, 235,000 tons at \$6.....	1,410,000
Total value.....	\$17,557,025
Lumber and ties, 100,000,000 ft. at \$15.....	1,500,000
Total.....	\$19,057,025

NOVA SCOTIA

Dominion Coal Company—The output for February amounted to 201,570 tons of coal against 282,000 for February, 1908. March 3 the mine at Dominion No. 6 was closed down, throwing 500 men out of employment. The shutdown is for an indefinite period, only sufficient men to attend to the pumps being retained.

ONTARIO

Globe Refining Company—Port Elmsley, Lanark county, Ont. This company, of which Rinaldo McConnell, Ottawa, is president, has undertaken the manufacture of plumbago and installed a plant.

ONTARIO-COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ending Feb. 27, were as follows: Crown Reserve, 296,900 lb.; Cobalt Central, 40,375; City of Cobalt, 60,000; La Rose, 259,050; Nipissing, 212,675; Right of Way, 122,490; Threthewey, 65,000; total, 1,056,490 pounds.

Cobalt Lake—The annual meeting was held at Ottawa Feb. 27. The financial statement presented showed working expenses \$142,554, and proceeds including amounts due from smelter and value of ore on hand, \$83,547. During the year 3272 ft. of work had been done, comprising 3138 ft. of drifting and crosscutting, and 134 ft. of sinking, in addition to 18,000 cu.ft. of stoping.

Crown Reserve—Rich ore is being taken out at the 135-ft. level, the lowest depth worked. Assays show silver contents of 8500 oz. to the ton.

Chambers-Ferland—Two strikes were made this week. One vein was found in No. 1 shaft slope, and the other at the 80-ft. level in No. 2 shaft.

Kerr Lake—Three new veins have been discovered at the 100- and 150-ft. levels, giving a total width of 35 in. of ore. The Lawson vein has been cut at the 200-ft. level where it yields 7 in. of rich ore.

La Rose—Drifting is being done at the 180-ft. level on the big vein in both directions from the raise made from the 100-ft. to the 200-ft. level, and rich ore is being taken out.

Nipissing—During February \$75,000 of ore was taken out from sinking operations alone on the Fourth of July shaft, which is now down 165 ft. It will be put down to 200-ft. level before drifting is begun. The five veins found in the shaft at a depth of 125 ft. have united, forming 8 in. of ore. At the depth of 210 ft., vein 26 runs from 8 to 14 in. in width and the ore yields 4000 oz. of silver to the ton.

Right of Way—A quarterly dividend of 6 per cent. with a bonus of 9 per cent. has been declared payable April 1. A 6-in. vein carrying silver has been found at the 100-ft. level.

ONTARIO—MONTREAL RIVER DISTRICT

Otisse—A small vein encountered in the shaft at 43 ft. has steadily widened with depth and increased in silver contents. At 55 ft. it has developed into a strong vein with ore assaying 3000 oz. to the ton, the walls on each side also carrying silver making a shipping body 3½ to 4 ft. in width.

Mexico

CHIHUAHUA

Cia Minera Londres—The lead-silver-zinc mine is nine miles from Guzman, on the Sierra Madre railway, and 70 miles from El Paso. Dr. Samuel Blair, of Albuquerque, N. Mex., is managing director and J. D. Hedding, general manager. The equipment includes 10x14 Ottumwa engine, 100-horsepower boiler, compressor and machine drills. The ore occurs in pockets along a lime-porphry contact. Thirty-five Mexican miners are employed. Wages range from 85c. to \$2 per day. Two machines are operated on the seventh level. On this level a new oreshoot has been found. The work is done by contract, the prevailing price being \$6 per ft. Coal costs \$8 per ton, laid down at the mine, and ore is hauled to the railway at \$3. Excellent stone houses are furnished miners.

San Pedro—The Candalaria mine has installed a new pump, and is now shipping a small quantity of ore.

Cerro Colorado—The opening up of a large body of shipping-grade lead-silver ore at the Creel mine in the Cerros Colorados section to the east of Villa Ahumada is reported. Assays show 50 oz. silver and 50 per cent. lead. The property is under development by Mexico City men represented by Sr. Manuel Lujan, of Chihuahua.

San Toy—Daily shipments of more than 100 tons of 40-oz. silver ore are being made from the Juarez mine and production will be shortly resumed at the Galeana mine, doubling the present output. Donald B. Gillies, the manager of the company, as well as other Schwab mining interests in the United States and Mexico, is now spending most of his time at Chihuahua directing San Toy operations.

GUERRERO

Balsas—Work is nearly completed on the 100-ton copper-smelting plant for the Maine & Nebraska Mining and Smelting Company. This work is in charge of Walter E. Koch, of El Paso.

SONORA

The Tigre Mine—The company is working 250 Mexicans, treating about 100 tons of ore a day and shipping about 300 tons of concentrates a month. Robert Musgrave is manager.

Sonora Copper Smelting Company—Shipments of ore are being made to the El Paso smelter. Over a mile of underground work has been completed. A. M. Conrad is manager. The main working tunnel is in 1300 ft., which gives a depth of 650 ft.

Harris Copper Company—A core drill is being used to prospect the La Caradad mine, Nacozari; other development is discontinued.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, March 10—The coal trade in the West shows some improvement, and in several quarters mines are reported running on longer time and with increased orders. At the principal centers an improvement is reported in the demand for steam coal.

A set-back to optimistic sentiment has been given by the receivership for the Deering Coal Company. This is one of the large combinations made at the height of the prosperous period and heavily capitalized. It is uncertain what the result may be, but the company has evidently felt seriously the effects of the past year. The report of the Pittsburg Coal Company, just issued, shows that it has passed the worst year in its history but has been able to meet its obligations.

In the East the bituminous-coal trade continues quiet. The Seaboard trade shows some improvement, but rather slow, although producers are beginning to feel more hopeful.

In conference with representatives of some of the anthracite companies the miners' leaders have arranged for a meeting to be held on March 11 to consider the proposed new agreement. This will be only a preliminary meeting, however, and it is not at all likely that any definite results will be reached until later. The strike talk, however, is not quite so loud.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburg and Erie, year to Feb. 27, short tons:

	1908.	1909.	Changes.
Anthracite.....	857,717	769,675	D. 88,042
Bituminous.....	5,246,482	5,519,214	I. 272,732
Coke.....	1,161,703	1,624,222	I. 462,519
Total.....	7,265,902	7,913,111	I. 647,209

The total increase this year to date was 8.9 per cent.

Coal and coke tonnage reported by the Pittsburg Coal Company for the year ended Dec. 31, short tons:

	1907.	1908.	Changes.
Pittsburg district..	18,005,382	13,217,545	D. 4,787,837
Hocking district..	1,348,312	1,064,586	D. 283,726
Total coal.....	19,353,494	14,282,131	D. 5,071,363
Coke.....	456,993	55,099	D. 401,894

The decrease in coal in 1908 was 26.2 per cent.; in coke, 87.9 per cent.

Coal shipments of the Monongahela River Consolidated Company for the three months of its fiscal year from Nov. 1 to Jan. 31, short tons:

	1908.	1909.	Changes.
River coal.....	1,523,765	910,929	D. 612,836
Rail coal.....	417,242	198,124	D. 219,118
Total.....	1,941,007	1,109,053	D. 831,954

The total decrease in shipments this year was 42.9 per cent.

Anthracite shipments in February were 4,576,004 tons, being 607,341 tons less than in January, and 72,248 tons less than in February, 1908. For the two months ended Feb. 28 the shipments were, in long tons:

	1908.	1909.	Changes.
Reading.....	1,933,434	1,982,656	I. 49,222
Lehigh Valley.....	1,703,680	1,642,908	D. 60,772
N. J. Central.....	1,324,302	1,204,980	D. 119,322
Lackawanna.....	1,573,001	1,357,001	D. 216,000
Del. & Hudson.....	1,071,627	1,037,869	D. 33,758
Pennsylvania.....	961,004	859,088	D. 101,916
Erie.....	1,107,954	1,214,583	I. 106,629
N. Y., Ont. & West.	447,193	400,264	D. 46,929
Total.....	10,122,095	9,759,349	D. 362,746

Three companies—the Philadelphia & Reading, the Erie, and the New York, Ontario & Western—report increases. The others show decreases, the largest being on the Delaware, Lackawanna & Western. The total decrease this year was 3.6 per cent.

New York

ANTHRACITE

March 10—Business shows no change whatever. Demand has been about on the usual level and domestic sizes have moved very slowly. Steam sizes are a little more in demand and the supply is somewhat better, though it is still not excessive. Strike talk is now waiting for the results of the conference to be held this week.

Prices are unchanged. The list prices for prepared sizes are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points.

BITUMINOUS

The soft-coal trade continues rather dull, and the closing of yearly contracts is proceeding very slowly. It does not seem to be easy to agree upon prices, unless producers are willing to work without profit. In current business the far East is sending a few more inquiries, but is not buying much. The Sound is a little more active and more inclined to take coal.

New York harbor is still rather dull. Buyers seem to be inclined to take coal only when they can get it cheap, while producers are rather holding back and are inclined to ship only on orders. Good

grades of steam coal are still quoted at \$2.40@2.50 f.o.b. harbor shipping point, with lower grades \$2.20@2.30 per ton.

All-rail trade is improving a little and is much better than Coastwise business. Car supply is abundant and transportation is fully up to schedule, cars sometimes coming through a day or two before they are expected.

The Coastwise-vessel trade shows no improvement, and captains are almost tired of hunting for charters. Rates are unchanged, those quoted for large vessels from Philadelphia being: Boston, Salem and Portland, 75c.; Lynn and Bath, 85c.; Portsmouth, 80c.; Newburyport, 95c.; Providence, New Bedford and the Sound, 65@70c. per ton.

Birmingham

March 8—There is no improvement in the coal trade in Southern territory, and several mines are either shut down or running on slack time. All demands can be met and the production can be increased on very short notice.

Coke production is also at a low ebb. The demand amounts practically to nothing. The Tennessee company still has a large quantity of coke on hand for use when the iron production improves.

It has been some time since the coal and coke market in this section has been as quiet as it is now.

Chicago

March 9—A quiet but firm tone exists. The situation as regards demurrage is improving, forced sales being fewer and the quantity of coal coming to market being more nearly uniform from both eastern and western mines. With the probability of cold waves over, the tendency of retailers and consumers is to buy lightly and wholesalers will keep down their stocks correspondingly. Domestic coals still vary greatly with the weather; steam coals are holding steadily and are running to finer coals more largely.

Lump and egg from Illinois and Indiana mines sells in car lots at \$1.75@2.50, run-of-mine \$1.65@1.75 and slack \$1.25@1.50. Smokeless is much firmer owing to restriction of shipments and forced sales are no longer the rule. Lump brings \$3.15@3.45 for Pocahontas and New River and run-of-mine, same grade, \$2.75@3.15; lower grade smokeless sells for \$2.95@3.30 for lump, and \$2.75@2.95 for run-of-mine. Brazil block is steady at \$2.85.

Hocking Valley holds up to \$3@3.15, with the supply held down closely to needs of the market. Youghiogheny is quiet at \$3.15 for ¾-in. gas lump. Pittsburg No. 8 is in comparatively light demand at \$2.65 @2.75.

The anthracite market has subsided into its usual quiet condition.

Cleveland

March 9—The coal market is dull for the present. Domestic coal has fallen off on account of the weather. Steam coal gains slowly. Prices are low. Negotiations are in progress over supplies for the Lake trade. Something depends upon the rate question, and shippers are waiting the decision of the Interstate Commission on the Pittsburg application for equalization of railroad rates.

Indianapolis

March 8—There has been a slight increase in the output of the coal mines during the past week. The Vincennes division of the Vandalia railroad brought out 50 carloads of coal a day for local shippers who ship it on to points north, some of it going to Chicago and other Lake points. A number of mines on this line have benefited by the transfer of large orders from the Deering Coal Company by the Steel Corporation, and this has taxed the road's facilities considerably. Operators say that the mines are now running from three to six days per week, with orders steadily increasing. It is not believed that the receivership of the Deering company's property will keep that company's mines closed. In some instances, notably in Sullivan county, the Milred and the Willford, two of the best mines owned by the company, have received orders from the receiver to continue work.

Pittsburg

March 9—There has been no change. The large producers continue to quote on the basis of \$1.15 for mine-run coal at mine on both spot and contract. Some small independents, however, are willing to sell at less and some spot sales have been made lately at close to \$1 a ton. Large Lake coal shippers are still making contracts with Pittsburg producers for the coming season. The surplus coal of the Pittsburg-Buffalo Company will go to the Hanna interests, which are likely to be the heaviest shipper to the north-western markets in the summer. The rivers are still navigable; yesterday two large tows went to the Cincinnati market and there is but little left for shipment this week. All the river mines are being operated at capacity, while the railroad mines are not going to more than one-third of capacity.

Connellsville Coke—The coke trade is

stagnant and but few contracts for any grade are being made. Large producers continue to hold furnace coke at \$1.75 for both spot and on contract, and foundry coke is being quoted at \$2@2.25, according to delivery. The prospects at the present time are not regarded as good. The *Courier* gives the production in both fields at 268,852 tons. The shipments were 9630 cars as follows: To the Pittsburg district, 3341; to points west of Pittsburg, 5543; to points east of Connellsville, 746 cars.

Foreign Coal Trade

United States Coal Exports—Exports of coal and coke from the United States, with coal furnished for use of steamships, month of January, long tons:

	1908.	1909.	Changes.
Anthracite.....	160,465	165,092	I. 4,627
Bituminous	743,922	649,090	D. 194,832
Total coal.....	904,387	714,182	D. 190,205
Steamer coal.....	619,970	427,743	D. 92,227
Total.....	1,424,357	1,141,925	D. 282,432
Coke.....	79,120	74,481	D. 4,639

Canada took this year 489,487 tons coal or nearly 70 per cent. of the total.

United States Coal Imports—Imports of coal and coke into the United States, month of January, long tons:

	1908.	1909.	Changes.
Anthracite.....	5,909	3,103	D. 2,806
Bituminous.....	149,117	99,109	D. 50,008
Total coal.....	155,026	102,212	D. 52,814
Coke.....	20,156	13,028	D. 7,128

Canada furnished this year 76,141 tons coal and nearly all the coke; Australia, 15,680 tons coal. Imports are chiefly on the Pacific Coast.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on Feb. 27: Best Welsh steam, \$3.36; seconds, \$3.24; thirds, \$3.12; dry coals, \$3.48; best Monmouthshire, \$3.06; seconds, \$2.94; best small steam, \$2.10; seconds, \$1.80. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, March 10—The iron and steel markets are gradually adjusting themselves to the new conditions and some increase in business is manifest. The improvement is not rapid, but is going on slowly, as was to be expected under all the circumstances. In some quarters there is a disposition to attribute delay to tariff possibilities, but in others little attention is paid to this. It is manifest, however, that there is a more confident tone and an increasing disposition to place orders for some time ahead and to rely less on immediate purchases.

In the structural-steel market a good deal of business is being done and con-

struction requirements are coming forward rather freely. Inquiries are numerous, though not all of them lead to immediate business. It looks now as though the summer will see a good deal of structural work. In bars a good business has been done and in plates there is also more demand.

The large New York Central order for steel rails has not so far been followed by others; but it is said that some important negotiations are in progress. Several orders for steel cars have been placed and others are expected, while railroad-bridge orders are coming in more freely.

In pig iron there has been a considerable volume of business and though it is mainly in small orders the total volume is increasing, while individual orders show a tendency to advance in quantity. Pig-iron prices are a little variable, and there is more or less shading when a desirable order is in question.

Nothing definite has yet been done about iron-ore prices for the season. The Lake interests are holding back but there is a growing impression that prices will not be materially changed.

The question of wages is still under discussion. The Phoenix Iron Company has ordered a general reduction of 10 per cent. and some smaller companies have taken the same action. At a meeting of the Eastern Pig Iron Association held this week it was resolved that a general reduction of 10 per cent. was necessary, but the carrying out of this was left to the members.

Pig Iron Production—The reports of the blast furnaces, as collected by the *Iron Age*, show that on March 1 there were 232 coke and anthracite stacks in blast, having a total weekly capacity of 421,000 tons. This is an increase of 6500 tons over Feb. 1 and of 19,000 tons over Jan. 1. Making allowance for the charcoal furnaces the production of pig iron was, approximately, 1,726,000 tons in February; for the two months ended Feb. 28 it was 3,547,000 tons.

Canadian Rail Contracts—The Dominion Steel Company has secured a contract for 30,000 tons of steel rails for the Grand Trunk Pacific, the price being \$33.50 per ton, delivered at Prince Rupert. The company has also taken a contract for 15,000 tons of rails to go to Australia.

Birmingham

March 8—The Southern pig-iron market shows little improvement. One company announces the sale of quite a quantity of iron, something like 80,000 tons having been disposed of during the first two months of the year. Prices are a little weak. The shipments of pig iron from Southern territory continue steady. The make is holding up well. Two furnaces which are under repair are re-

ported ready to start when the iron is needed. The Southern iron manufacturers will be able to meet all demands when the market improves. The cast-iron pipe companies in this section have recently been bidding on some big contracts and are assured of landing the business. These interests are already in possession of orders that will keep them busy for some time to come. The steel plant at Ensley is still practically in full operation.

The properties of the Southern Steel Company have been advertised for sale and the reorganized company, with W. H. Hassinger president, will in a short time be in possession and will take steps looking to operation.

Pig-iron quotations revolve around \$12 to \$12.50 per ton, No. 2 foundry.

Baltimore

March 9—Exports for the week included 405,336 lb. spelter, 574 lb. selenium, 2,616,700 lb. steel billets to Liverpool; 2512 tons steel rails and 1,247,810 lb. structural steel to Panama. Imports included 5850 tons iron ore from Cuba.

Chicago

March 9—Buying of pig iron is very light. Practically every melter of consequence is holding off until he sees how the market skies will clear under the clouds of tariff revision, lowered steel prices and recovery of confidence. Hardly a buyer is in the market for last-half iron; the business of today is done on short-order schedule. Sales are for deliveries within 30 to 90 days and for small amounts.

Prices are uncertain. The disposition of furnace agents is to grant concessions and \$12 Birmingham undoubtedly represents certain contracts. This means \$16.35 Chicago, against \$16.50 for Northern iron, No. 2 being quoted in both cases.

Above these amounts 25 to 50c. is obtained on some sales. A prospect of the sale of a large amount of iron on six to nine months' delivery would bring out a few quotations.

An effort is being made by the Southern representatives to hold up prices to \$13 Birmingham (\$17.35 Chicago) on ordinary purchases. This apparently cannot stand in the face of present conditions.

Philadelphia

March 10—Nothing can be said concerning the pig-iron market that is encouraging either to sellers or buyers. Both forge and foundry continue extremely dull. The makers of pipe iron are encouraged with the belief that a great deal of pipe iron will be wanted within the next 60 days. The mills have been buying very little forge, and foundries are booking very little new business. It was expected

that this week would bring out a large amount of business in basic iron, but a hitch has occurred somewhere, the details of which cannot be ascertained.

Steel Billets—Reductions which have been made verified the prediction which had been made all along. The base price of \$23 at mill is believed to be the lowest probable level.

Plates—Plates have been very quiet for a week. The demand is for small lots for local requirements.

Structural Material—No large business will be done in structural material until the disturbing influences subside. Just what is disturbing the local market is unknown and the manufacturers have very little to say on the subject, except that the independent manufacturers are occupying a position of antagonism to the larger interests.

Scrap—The scrap market is very much disturbed. Very little material is being sold. The dealers are loaded up, considering the present condition of the market. Prices are merely nominal and buyers are looking for a further weakness.

Pittsburg

March 9—Business in the iron and steel trade has not improved materially. There is a hesitancy on the part of buyers to contract for their spring requirements until there is a more definite understanding as to the future. The market can, therefore, be regarded as a waiting one, but some business must be done regardless of prices as consumers must have material. The uncertainty as to the tariff is the main stumbling block in the way of a good buying movement at this time, and where it is possible to wait until this question is disposed of consumers have decided to do so.

The feature of the finished-steel market this week is the uncertainty regarding wire and wire products. There is fairly good information that before the end of the week the leading interest, the American Steel and Wire Company, will announce a stiff reduction in prices for the spring trade. Jobbers who have been accustomed to fill their warehouses early in March for the spring trade have delayed sending in their orders. Some business has been booked this week, but it has not been up to what actually will be required and there is no doubt but that a concession in the price will bring out a considerable tonnage.

There was some stir in Pittsburg last week when a report was circulated that billets had sold at \$20 a ton at mill in Youngstown. This was positively denied by all billet makers in this and surrounding territory. It was admitted that at a meeting held here on Thursday, it had been decided to cut the price of both open-hearth and bessemer billets from \$25, Pittsburg, to \$23 and to eliminate the

division of freight. Sheet bars and tin-plate bars were cut from \$27.50 to \$25.50, Pittsburg, for delivery in Youngstown, Wheeling, McKeesport and Mingo Junction.

Pig Iron—There is scarcely any improvement. Actual sales do not exceed 1000 tons. Inquiries aggregate about 10,000 tons, but of these 6000 tons are for malleable bessemer and come from the East; it is probable the business will be placed in Buffalo territory as the freight rate from the Valley furnaces is heavier. The Westinghouse Air Brake Company is in the market for 1000 tons of bessemer iron. Prices are practically unchanged and are as follows: Standard bessemer, \$15.50; malleable bessemer, basic and No. 2 foundry, \$15; gray forge \$14. It is understood basic can be shaded.

Steel—Merchant-steel bars are now 1.20c. and plates 1.40 cents.

Sheets—Independents are quoting \$2 per ton higher than the minimum price supposed to have been announced by the leading interest. Their latest quotation, subject to change, is as follows: Black sheets, 2.30c. and galvanized sheets, 3.35c. for No. 28 gage.

Ferro-Manganese—Prices have dropped \$1 a ton; quotations for prompt shipment are \$13@14.50, Pittsburg.

Foreign Trade in Iron and Steel

Iron and Steel Exports—Exports of iron and steel, including machinery, from the United States for the month of January are valued by the Bureau of Statistics of the Department of Commerce and Labor at \$13,468,058 in 1908, and \$10,329,388 in 1909; decrease, \$3,138,670, or 23.3 per cent. Leading items of export, in long tons:

	1908.	1909.	Changes.
Pig Iron.....	2,546	3,213	I. 667
Billets, ingots & blooms	5,317	9,506	I. 4,189
Bars.....	5,507	3,589	D. 1,918
Rails.....	16,285	13,187	D. 3,098
Sheets and plates.....	7,888	8,532	I. 644
Structural steel.....	11,017	6,453	D. 4,564
Wire.....	12,922	9,123	D. 2,899
Nails and spikes.....	3,686	3,579	D. 107
Pipe and fittings.....	6,975	9,166	I. 3,091

Decreases are shown in all the more important items this year.

Iron and Steel Imports—Imports of iron and steel and of machinery into the United States in January were valued at \$2,076,766 in 1908, and \$1,830,071 in 1909; decrease, \$246,695, or 11.9 per cent. The leading articles of import were, in long tons:

	1908.	1909.	Changes.
Pig Iron.....	15,387	11,048	D. 4,339
Scrap.....	678	169	D. 509
Ingots, blooms, etc.....	759	1,413	I. 6.4
Bars.....	4,066	2,318	D. 1,748
Wire-rods.....	1,163	1,022	D. 141
Thinplates.....	8,907	3,767	D. 1,490
Sheets and plates.....	353	208	D. 145

The only increase reported this year was in ingots and blooms.

Metal Market

New York, March 10.—The markets still continue rather quiet, and no improvement is noted for the week.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Jan. 1909..	\$ 7,865,196	\$ 3,412,583	Exp. \$4,452,613
" 1908..	444,200	10,799,484	Imp. 10,355,284

" 1908..	4,146,144	3,621,874	" 526,270
Year 1909..	4,642,264	3,660,062	Exp. 882,202
" 1908..	4,146,144	3,621,874	" 526,270

Exports from the port of New York, week ended March 6: Gold, \$3,278,100, chiefly to Argentina; silver, \$1,017,974, chiefly to London. Imports: Gold, \$709,148; silver, \$70,254, both from the West Indies, Mexico and South America.

Gold—The price of gold on the open market in London continues unchanged at 77s. 9d. per oz. for bars and 76s. 4d. per oz. for American eagles. The Bank of England is absorbing most of the new supplies. In New York \$2,500,000 in gold have been shipped to Argentina, and at the close of the week \$3,000,000 are reported taken for shipment to London.

Platinum—Dealers' prices continue unchanged at \$23.50@24.50 for refined platinum; \$26 for hard metal and \$19@21 for scrap. Business is improving a little, but is still rather quiet. Some change is expected soon.

SILVER AND STERLING EXCHANGE

Mar.	4	5	6	8	9	10
New York....	50½	50½	50½	50½	50½	50½
London.....	23½	23½	23½	23½	23½	23½
Sterling Ex. .	4.8770	4.8780	4.8810	4.8825	4.8820	4.8800

New York quotations, cents per ounce troy, fine silver; London, pence per ounce sterling silver, 0.925 fine.

Silver—Some India bazar and China buying has carried the price up slightly, but there does not seem to be any special feature in the market.

Copper, Tin, Lead and Zinc

Mar.	Copper.		Tin.	Lead.		Zinc.
	Lake, Cts. per lb.	Electrolytic, Cts. per lb.	London, £ per ton.	Cts. per lb.	New York, Cts. per lb.	St. Louis, Cts. per lb.
1	12½	12½		3.92½	3.77½	4.57½
4	@13	@12½	56½	@3.95	@3.80	@4.62
5	12½	12½		3.92½	3.77½	4.57½
6	@13	@12½	56½	@3.95	@3.80	@4.62
7	12½	12½		3.92½	3.77½	4.57½
8	@13	@12½	56½	@3.95	@3.80	@4.62
9	12½	12½		3.95	3.80	4.57
10	@13	@12½	56½	@3.97	@3.82	@4.62

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—In the week of March 4-10 there were some transactions of important size, chiefly for export. Domestic business was comparatively small. However, some of the large manufacturers appear to have been privately taken care of by certain producers. The price asked of domestic consumers is now 12½c., delivered 30 days, corresponding to about 12½c., cash, New York, but sales for export have been made in large volume at a somewhat lower price. The buying power which was reported last week has lost its force. Domestic consumers seem for the time being to have satisfied their requirements, and European buyers can only be induced to take additional quantities by being offered concessions below the ruling quotations. The trade generally has been awaiting the figures of the Producers' Association, which were published on March 10, and show an increase in the visible supplies of about 29,000,000 pounds. The publication came too late to enable a judgment of the effect on the market prior to going to press. Meanwhile prices close dull and nominal at 12½@13c. for Lake copper; 12½@12½c. for electrolytic in ingots, cakes and wirebars. The average of the week for casting copper has been 12½@12½ cents.

The London standard market has fluctuated within narrow limits. Considering the uncertainty which is generally felt about the future of the market, it has taken the realization of speculative holdings relatively very well. The close is somewhat lower at £56 5s. for spot, £57 for three months.

Refined and manufactured sorts we quote: English tough, £61; best selected, £60@61; strong sheets, £72@74.

It is gossiped that the International Smelting and Refining Company holds an option on the Raritan copper refinery of the United Metals Selling Company.

Copper Producers' Association—The statement for March 1 shows stocks of marketable copper of all kinds on hand at all points in the United States, Feb. 1, were 144,130,045 lb.; production of marketable copper in the United States, from all domestic and foreign sources during February, 103,700,817 lb.; total supply, 147,830,862 lb. Deliveries of marketable copper for consumption and export during February, 74,546,614 lb.; stocks of marketable copper of all kinds on hand at all points in the United States, March 1, were 173,284,248 lb. The increase in stocks was 29,154,203 lb. during February.

Tin—The market in London as well as here has been rather dull throughout the

week, but retained its firm undertone. Business done was on a small scale. The London close is cabled at £130 5s. for spot, £131 15s. for three months, while New York dealers quote the market at 28½c. cents.

Lead—Business was somewhat more active, particularly early in the week. The cheap lots of Missouri lead which were floating about the market appear to have been absorbed and holders now are trying to get an advance. The market closes steady at 3.89@3.82½c. St. Louis, 3.95@3.97½c. New York.

The London lead market has been holding steady and closes unchanged at £13 7s. 6d. for Spanish lead, £13 10s. for English lead.

There is a certain amount of truth in the report cabled last week from Paris to the *Journal of Commerce* respecting a meeting of lead producers to consider the organization of a convention similar to that which has been effected among the producers of spelter, but the plans have not yet reached beyond a general discussion. The meeting was attended by representatives of certain American smelting interests. Insofar as American production and consumption of lead are concerned, we are, of course, quite independent of European conditions so long as a tariff is maintained, but the desilverizers in this country refine a great deal of Mexican lead in bond, which is exported to Europe, wherefore the interest of American refiners in the European market.

Spelter—The brass manufacturers are reported to have placed some orders, but business for galvanizing purposes has been of a retail character. Quotations are unchanged throughout the week at 4.72½@4.77½c. New York, 4.57½@4.62½c. St. Louis.

Base price of sheet zinc is now 6¼c. per lb., f.o.b. La Salle-Peru, Ill., less 8 per cent. discount.

The London market is lower at £21 10s. for good ordinaries, £21 15s. for specials.

Other Metals

Antimony—The market is dull, and only a retail trade has been done. In the absence of business, quotations are nominal at 80@8½c. for Cookson's; 7½c. for Hallitt's; 7½@7½c. for ordinary brands.

Aluminum—Quotations by the manufacturer here are unchanged at 24c. base for No. 1 ingots and 33@34c. base for sheets.

Quicksilver—A fair business has been done, but New York quotations are unchanged at \$45@46 per flask of 75 lb. San Francisco is nominal at \$45 for domestic orders and \$43 for export. London price is £8 7s. 6d. per flask, with £8 6s. 3d. quoted by jobbers.

Cadmium—Currents quotation 75c. per lb., in 100-lb. lots, at Cleveland, Ohio.

Magnesium—Quotations for this metal are \$1.25 per lb., New York, in 100-lb. lots; for 5-lb. lots, \$1.40 per pound.

Imports and Exports of Metals

Exports and imports of metals in the United States for the month of January are reported as follows, in the measures usual in the trade:

Metals:	Exports.	Imports.	Excess.
Copper, long tons.....	21,012	9,662	Exp. 11,350
Copper, 1908.....	33,003	6,599	Exp. 26,064
Tin, long tons.....	19	4,196	Imp. 4,177
Tin, 1908.....	33	1,155	Imp. 1,122
Lead, short tons.....	7,466	9,966	Imp. 2,501
Lead, 1908.....	6,136	7,051	Imp. 915
Spelter, sh. tons.....	364	283	Exp. 81
Spelter, 1908.....	210	31	Exp. 179
Nickel.....	63,575	853,530	Imp. 218,054
Nickel, 1908.....	867,540	1,343,179	Imp. 487,361
Antimony, lb.....	884,147	Imp. 884,147	
Antimony, 1908.....	709,245	Imp. 709,245	
Platinum.....	12,456	Imp. 12,456	
Platinum, 1908.....	3,312	Imp. 3,312	
Quicksilver, lb.....	7,553	Exp. 7,553	
Quicksilver, '08.....	11,730	Exp. 11,730	
Aluminum, value.....	\$3,883	Exp. \$3,883	
Aluminum, 1908.....	5,816	Exp. 5,816	
Ores, etc.:			
Zinc oxide, lb.....	1,639,270	Exp. 1,639,270	
Zinc oxide, '08.....	1,072,182	Exp. 1,072,182	
Zinc dross, lb.....	1,698,563	Exp. 1,698,563	
Zinc dross, '08.....	3,567,134	Exp. 3,567,134	
Zinc ores, lg tons.....	9,096	Imp. 9,096	
Zinc ores, 1908.....	4,048	Exp. 1,603	
Antimony ores, lb.....	1,491,128	Imp. 1,491,128	
Ant. ores, 1908.....	118,945	Imp. 118,945	

Copper, lead and nickel include the metal contents of ores, matte, bullion, etc. The exports given include reexports of foreign material. Imports of zinc ores in 1909 included 1588 tons calomine and 7508 tons other ores; against 1610 and 835 tons last year.

Zinc and Lead Ore Markets

Platteville, Wis., March 6—The base price paid for 60 per cent. zinc ore was \$37.50 per ton. No premium reported. For 80 per cent. lead ore, \$46 per ton was paid.

SHIPMENTS, WEEK ENDED MAR. 6

Camps.	Zinc	Lead	Sulphur
	ore, lb.	ore, lb.	ore, lb.
Hazel Green.....	411,600		
Benton.....	331,200		
Platteville.....	324,900	209,400

Total.....	2,013,603	209,400	
Year to Mar. 6.....	19,381,189	656,180	1,699,600

In addition to the above there was shipped to the American Zinc Ore Separating Company 170,170 lb., and to the Joplin Separator Works, 319,500 lb. zinc ore.

Joplin, Mo., March 6—The highest price paid for zinc sulphide ore was \$40 per ton. As high as \$38 base was paid for particularly choice ore, but the bulk of better grades sold on \$37@37.50 base. The low base was \$35 for slimes with \$35.50@36.50 paid for ores of upward grade. Zinc silicate sold as high as \$25, on a base of

\$18@19 per ton of 40 per cent. zinc. The average price, all grades, was \$34.08 per ton.

Lead advanced toward the close of the week, as the metal market improved, selling at \$51, which was paid for several bins. The bulk of shipments were on a base of \$38@40 per ton of 80 per cent. lead. The average price, all grades, was \$38.40 per ton.

The market appeared featureless on the surface, but a strong undercurrent was noted in zinc sulphides as the week progressed. This was occasioned by the receipt of a heavy shipping order by one of the purchasing agencies. A quiet canvass was made for the ore, and most of the 1000 tons was picked up at current prices without disturbing the market.

NOTE.—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

Chemicals

New York, March 10—The general market is still quiet. Though a little business is being done, consumers still seem reluctant to buy far ahead.

Copper Sulphate—Business is on a moderate basis only. Prices quoted by dealers are \$4.60 per 100 lb. for charcoal

lots and \$4.85 per 100 lb. for smaller parcels.

Arsenic—Business has not been large. Sales for the week amount to possibly 100 tons, at 3c. per lb. for white arsenic.

Nitrate of Soda—Indications in this article are better, and more business has been done, the result being a rather higher price for futures. Quotations are 2.15c. for both spot and future positions.

Imports and Exports—The imports and exports of chemicals and raw materials in the United States, month of January, were as follows:

	Imports.	Exports.	Excess.
Copper sulph. lb.....	969,404	E. 969,404	
Bleach, lb.....	7,510,746	E. 1, 7,510,746	
Potash salts, lb.....	36,785,235	E. 36,326,436	458,819
Soda salts, lb.....	834,932	E. 29,600	805,332
Acetate lime, lb.....	5,669,062	E. 6,059,062	
Nit. of soda, tons.....	13,180	E. 743	12,437
Phosphates, tons.....	150	E. 44,035	44,035
Sulphur, tons.....	3,086	E. 5,817	2,781
Pyrites, tons.....	42,687	E. 1	42,687

Estimating sulphur contents of pyrites, the total sulphur imported was approximately 20,011 long tons.

Mining Stocks

New York, March 10—The general stock markets during the past week have been irregular and rather inclined to weakness. There have been reductions in prices in a number of stocks, but some of these have recovered, while others have failed to feel the benefit of any reaction. The whole tone of the market is uncertain, and the fluctuations from day to day have had very little meaning.

In the Curb market the copper stocks have not been strong. Prices have not held their own, but have fallen whenever there was selling on any considerable scale. The market, however, has been inclined to dullness and the transactions, as a rule, have not been heavy. The Cobalt stocks have been rather stronger and more in demand than last week and have made a better showing than any other class. The Nevada gold stocks have been dull, and buying has not been at all active.

Boston, March 9—The stock market this week has had lots of ups and downs, but on the whole it has been not encouraging and rather inclined to weakness. The condition of the copper market, gold shipments to Europe and the temporary position of the banks have not tended to encourage speculation. Sales have been fair in amount, but buyers have been rather shy. Upon the whole it was a traders' market throughout.

Amalgamated was a strong feature, as usual, but has not held its own. It closes today at \$67.50, which is \$1.50 off from the highest of the day. The Boston specialties show no pronounced features. There was some activity in Parrot on reports that the lower drifts would soon reach the Anaconda vein. Nevertheless,

We Repeat

The Newest Books on Mining Methods in Europe

By L. W. Mayer, E. M.

\$2.50 (10 6) net postpaid

The keynote of this book is the maximum of extraction with the minimum of cost. Europe leads us in this, but in this book, Mr. Mayer embodies the results of a careful investigation of their methods and shows what can be advantageously applied to American mining problems. The Caving System, The Longwall and many other important features are included.

The Chapter Headings

PART I—MINING IN GREAT BRITAIN—Mining in Great Britain. Parkside Mine, Cumberland. Creator Moor Mine, Cumberland. Ulcoat Mine, Cumberland. Hodbarrow Mine, Cumberland. Longwall Methods of Mining Flat Seams. Seaton-Delaval Colliery, Northumberland. Chopwell Colliery, Northumberland. Kimblesworth Colliery, Northumberland. Watnall Colliery, Midland District. Coal Mining in South Staffordshire. Spawood Iron Mine, Yorkshire. Park Pit, Yorkshire. Oakley Slate Quarries, North Wales.

PART II—MINING IN GERMANY, FRANCE AND OTHER COUNTRIES—Lead Mining at Mechernich. Prussia. The Flushing System. Coal Mining in Silesia. Flushing System at Gute Hoffnung Lead Mine, Germany. Ilseide Hütte Iron Mine, Peina, Germany. Coal Mines of Carmaux, France. Notes on Mining, Timbering and Lighting.

Ore Deposits for the Practical Miner

By J. P. Wallace, M.D., E.M.

Cloth, \$3.00 (12 6); Leather, \$3.50 (15s) net, postpaid

Practical and sensible mining men sometimes short at discussions of the classifications of ore deposits. But no practical man would deny the value of this book—the boiling down and sifting of all the best of the theories for every day use. Not only is the subject covered fully in this way, but the formations of the biggest strike mines are described in full.

Contents

PART I—THE ORE MINERALS—The properties of minerals. Gold. Gold alloys. Lead and mercury tellurides usually containing gold. Silver ores. Platinum and iridium. Mercury. Copper. Lead. Zinc. Iron. Chromium. Manganese. Nickel. Tin. Tungsten. Antimony. Bismuth. Graphite. Asbestos. Mica.

PART II—THE ROCK-FORMING MINERALS, ROCKS AND ROCK DISPLACEMENTS—The rock-forming minerals. The rock-forming minerals, continued. The rocks. Igneous rock, acid group. Igneous rocks, basic group. Sedimentary rocks. Metamorphic rocks. Intrusive rocks and flows. Rock disturbances. Effects of rock disturbances.

PART III—GENERAL CHARACTERS AND CLASSES OF ORE DEPOSITS—Ore deposition. Observations on ore deposits in general. Fissure veins. Vein filling. Vein outcrops. Ore bodies. Prospecting veins by crosscut tunnels. Metasomatism of Replacement.

PART IV—SOME TYPES OF ORE DEPOSITS—With descriptions of the world's most famous deposits.

PART V—MINE VALUATION AND PROSPECTING—Mine valuation. Gold placers. The mining of gold placers. Prospecting. Value of prospects. Gleanings from the mining field.

The Great Falls Coalfield in Montana

Amalgamated Copper Company Is One of the Largest Coal Producers in the Northwest. Tail-rope Haulage Pulls 3500 Tons in 10 Hours

B Y A. T. S H U R I C K *

The Great Falls coalfield, from a commercial viewpoint, occupies a position probably unrivaled among the western coal operations and even with the high ash content of its coal, it ranks as the largest producer in Montana.

The area of workable coal included in this field is roughly about 230 square miles, its general dimensions being about 30 miles long by 8 miles wide. The term "workable coal" as here used is a misnomer, and signifies only its economic value from a consideration of the sur-

cidental coal horizon occurs about 60 ft. above the base of the Kootenai (Lower Cretaceous), which formation is here about 475 ft. thick, and is composed of alternating shales and heavy sandstones. Massive sandstones predominate near the bottom adjoining the coal horizon, and in some instances forming ideal roof and bottom conditions.

Probably an average haul for the entire field to Great Falls would be 18 miles, and to Butte 180 miles. It represents clearly the most Northwestern coalfield of any

interstratified bands of slate and bone. The district has no shipping facilities and consequently no extensive development has been done.

The Sand-Coulee district, lying about the center of the field was the first heavy producer, and at present has the largest output. Three important operations predominate; the Cottonwood Coal Company, the Nelson Coal Company, and the Gerber Coal Company, with a more than usual strong following of smaller operations, ranging from prospects to the large-

SURFACE PLANT AT THE BELT MINE SHOWING TIPPLE AND WASHERY BUILDING

face cover; in much of this area the coal will be found too thin to permit of its development as a practical coal-mining proposition, in the present era at least.

On the United States Geological Survey map, showing the coalfields of the United States, the Great Falls field lies in the western portion of the Judith Basin region on the extreme western border of the Northern Great Plains province. It is here classified as a bituminous coal, being one of the only two fields in Montana so classified.

The geology as a whole is simple, the measures being practically horizontal and no faults or displacements of any magnitude have yet been discovered. The prin-

magnitude in the United States, and will doubtless continue to be the predominating coal district from Great Falls to the coast.

PAST AND PRESENT OPERATIONS

The first authoritative examination of this field, of which there is any record, was made by members of the Transcontinental Survey in 1879. It was later reported on by Newberry acting for the Great Northern Railway, and again in 1891 by Weed of the United States Geological Survey, who submitted a very comprehensive report.

The westernmost portion of the field, or what is known locally as the Smith River district, has probably the thickest seams in the entire field; prospects in this vicinity show 18 ft. of coal with the usual

est operation practicable without steam equipment.

The Cottonwood Coal Company (a subsidiary of the Great Northern Railway) is the pioneer of the entire field and by far the largest operator in this particular district. They began active operations at Sand-Coulee in 1888 on the completion of the railroad, and produced about 300,000 tons in that year. Later, they changed their principal base of operations to Stockett, about five miles around from Sand-Coulee, where they have a complete equipment, including a washing plant unique in the history of the western coal industry. (See "A Bituminous Coal Breaker," Trans. Am. Inst. of Min. Eng'rs. Vol. 35 Stockett.)

The first work done in the Belt Valley

*Engineer, coal properties, Amalgamated Copper Company, Washoe, Montana.

district was in 1877 and from then until the advent of the railroad, in 1889, from 500 to 1000 tons per annum was freighted across to Fort Benton, which was then the head of navigation on the Missouri river, and much of the fuel was used to coal the steamers down the river.

In 1891 the Anaconda Copper Mining Company secured a lease on the Belt mine and succeeded in shipping sufficient coal to Butte to seriously threaten Wyoming operators who controlled this market, and brought about a much needed adjustment of prices. This was continued until 1894 when they bought the property outright and immediately started developing for a large output.

THE ANACONDA COPPER MINING COMPANY'S BELT MINE

The Belt mine, which is probably the largest coal mine with a single opening in the Northwest, is selected for detailed description:

At the time of the acquirement of this property by the Anaconda Copper Mining Company, it was the only producing coal property directly controlled by that company, and the result was that exceedingly heavy output demands were made upon it. Much credit is due the coal-department officials in meeting these demands, as they were probably unprecedented, even among the modern plants of that day in Pennsylvania and West Virginia.

Owing to the comparatively extreme irregularity in dips, both in pitch and direction, it has been necessary to adopt a more or less flexible system of working. The Main West entry, which is the main haulage-way was driven in 3300 ft. when an area of low coal, which came in with a pronounced upthrow in the bottom, was developed by the north entries; the Main West entries were then turned paralleling the line of the fault, and are now in 7600 ft. in this direction making the total distance from the mine mouth a trifle over two miles. In on this new course 1600 ft., a "hill" of such magnitude was encountered, that, for haulage purposes, it was found necessary to develop around it. The entries were turned on their original course again for 1500 ft., and then back at a rather sharp angle toward the Main West for 1800 ft., this being the present inside point of the main haulage. This haulage-way, including a short outside haul, is 7000 ft. long and 48 car trips, of $\frac{2}{3}$ tons to the car, are pulled by the tail-ropes system.

The track is laid with 30-lb. rails, both main and tail ropes are 1 in. in diameter, and the trip attains a speed of a little over 8 miles per hour. The maximum grade is 3 per cent, and is against the loads; 3500 tons of coal have been pulled in 10 hours on this haulage-way, before it was extended to its present length, and if the rock had been included it would

probably have been close to 4000 tons. Partings 550 ft. long are required as sidings on which to make up the trips, and there are at present two such partings, one at the 16th entry draining the territory from there into the face, and the other at the 12th entry to put pillar coal from the south side.

ENGINE-PLANES ARE USED

The secondary haulage is accomplished

About 20'		Sandstone
0' to 5' Very Irregular		Slate. Very persistent along Main West Entry but running out to the North and South.
10' to 12'		Head Coal. Heavy Gray Coal carrying 35% Ash
2' to 2' 0"		Top Coal. carries 24% Ash

4' to 5' Very Irregular		Occasional Flat Nodules. Good Coking Coal changing to Bone on N. & Clay on S.
12' to 13' Regular		Iron Coal. Coal and Bone closely inter-stratified. Worthless.
0' to 6' Very Irregular		Fire Clay
3' Exposed		Sandstone

The Engineering & Mining Journal, N.Y.

A DETAILED SECTION OF THE COAL SEAM AT THE BELT MINE

on the engine-plane system, with horses acting as auxiliaries in making up the trips. These engines, of which there are 8 in use, are duplex- using compressed air and ranging from 6x8 to 8x10 in., and use from $\frac{3}{4}$ in. to $\frac{7}{8}$ in. wire rope. They are located in the more elevated portions of the mine so the loads run by gravity to the partings on the Main West, and the

empties the same to smaller partings near the working face; from this latter point the empties are delivered to the working places by horses and the loads are made up into from 8 to 12 car trips. Eighteen horses are used on this work.

THE SYSTEM OF MINING

The general system of mining is simple, the main haulage centering on the Main West entry and cross entries being driven to the North and South with perpendicular distances of usually 500 ft. between them. All entries are driven on the usual double-entry system, with a 25-ft. pillar, and crosscuts about every 100 ft. Fig. 2 shows a portion of the inside workings typical of the mine as a whole. The contours, showing the topography of the bottom of the coal, exhibit clearly the irregularities of dip.

Rooms are turned every 50 ft. off those cross entries on both sides, and where the topography permits, are driven at right angles to the entry. It is essential that the rooms be driven slightly on the raise in order to be self draining, the mine being very wet; in some instances, however, where it has been necessary to go to the dip for short distances, the "Finlander Pump" (a tub set up near the roof with a trough leading to the room mouth) has given satisfactory results.

The most desirable room-and-pillar dimensions have been found to be a 30-ft. room with a 20-ft. pillar; a 30-ft. room with a 10-ft. pillar was attempted in one portion of the mine but resulted in a large and rather expensive squeeze. Where roof conditions are the best, a 50-ft. room and a 30-ft. pillar are used, the room being laid with two tracks one up each rib.

Mining is done entirely by the puncher machine; the company has about 30 of the Ingersoll-Sergeant Type G 2 machines, of which about 20 are in use at the present time. The machines work under severe conditions, the mining being hard and the seam thoroughly impregnated with exceedingly hard nodules of iron-pyrites. Eighteen picks are required per machine, per eight-hour shift, and the average work done by a machine is a cut 45 ft. long and 4 ft. 6 in. deep.

MINERS' WAGES

Machine runners are paid 11c. per ton, helpers 9c, and loaders $4\frac{3}{4}$ c., it being the duty of the latter to shoot the coal and keep the timber and track up in his place. Inside wages run from \$3.25 to \$4.00 for eight hours at the working face.

The mine is generally self draining, although in some of the lower portions small compressed-air pumps are required.

The ventilation is simple, the air being forced in through all working places to an up-cast shaft near the extreme inside workings, having a motive column of about 350 ft. The fan is of the Guibal type, 20 ft. in diameter, and driven by

a 12x16-in. engine direct connected. The mine has never been known to show any firedamp, which together with its exceeding wetness, and its generally good roof, places it among the safest mines in the west.

THE COAL

An accompanying drawing shows a section of the seam as it has been developed in this mine, showing clearly the maximum thickness of the coal-bearing strata which

unknown. A rough average analysis would be 51 per cent. carbon, 27 per cent. volatile, 18 per cent. ash and 3 per cent. sulphur. The foregoing analysis shows the one serious trouble of the field, the high ash content, for which the top coal is directly responsible. The bottom bench of coking coal was at one time mined separately and produced a coke that was equal to the Connellsville coke both in composition and physical structure. The ash content, in the coal, however, by the

by 16 ft. The boilers are located in batteries of two, there being one stack for each battery. A feature in connection with the boiler house, the importance of which is probably not generally appreciated among coal men, is the practice of carrying the weight of the large stacks on the roof trusses. In this case the boiler house is built of steel throughout, but a queen truss (which is generally the limit of the average mine carpenter) built up of 8x10 in. timbers, will readily carry

has been encountered, and the minimum which it has been found economical to work, together with the individual peculiarities common to each of the strata, such as its total change of character and uniformity.

This section forms an interesting exhibit of the persistent irregularities common to the western coals; it would be possible to compile many different sections from the one here shown, and the geologist would be puzzled to correlate them, were their stratigraphic positions

very thorough treatment outlined below, is reduced to 6.5 per cent.

THE SURFACE PLANT

The difficult treatment of the coal, made essential by the high ash content, and the large amount of power required in mining and hauling the coal inside, necessitates a rather elaborate surface equipment. The boiler plant is equipped throughout with the Tuttle Manufacturing and Supply Company boilers, there being ten 60 in. by 16 ft. and seven 54 in.

any ordinary load of this character on spans up to 38 feet.

POWER PLANT

Compressed air is furnished by a Corliss Cross compound condensing air compressor 24x48x24½ in. on the high pressure side, and 44x48x24½ in. on the low. A smaller compressor, 24x30x24½ in. acts as an auxiliary to the large one. Power is furnished the washer by means of a 300-h.p. rope-transmission system consisting of a 24x48 corliss engine driving a

20-ft. diameter wheel from which five 2-in. diameter manilla ropes run to the washer 235 ft. distant.

The electric-light equipment, furnishing about 1100 lamps from 16 c.-p. to 32 c.-p. for the works and the town, consists of a 12x12x20x12-in. Westinghouse compound high-speed engine driving a Westinghouse single-phase 1100-volt 50-ampere dynamo.

The haulage engine operating the tail-ropes system consists of two 15x18-in. cylinders driving directly a 6-in. shaft, which in turn gears back to two drums in the proportion of about 1 to 6. The two drums are 5 ft. 6 in. in diameter with 6-ft. faces and are so connected up that they may be thrown in and out of gear separately.

The machine shop is equipped with a lathe having a 26-in. swing and a 11-ft. base, a milling machine with a 42-in. base, a drill press with a 36-in. swing and a 6-in. pipe cutter all run by a 6x8-in. vertical engine. The blacksmith shop has five forges and an 800-lb. steam hammer.

The tippie is equipped with three Phillips dumps, one for coking coal and two to handle the run-of-mine, and owing to the large size of the trips, two stationary engines are used to handle the cars on the tippie. One engine, a 6x8-in. single cylinder vertical "dummy" pulls the loads down to the tippie by means of an ingenious endless-rope system using 1½-in. manilla rope. The other engine is the usual duplex mine haulage engine with 6x8-in. cylinders, and pulls the empties back up into the mine. A 30-in. circular saw driven by a 6x8-in. vertical engine is conveniently located to where the empty trip stands, and props are thus readily sawed to the required length and loaded.

THE WASHING PLANT

The washery has two board divisions, one handling the coking coal and the other the non-coking. The greater part of the equipment was made at the company's foundry and machine shops in Anaconda.

The non-coking coal on being dumped at the tippie passes down through two 24x30-in. crushers, one reducing to 4-in. and the other to a 2-in. size. The crushed coal passes into a Dodge conveyer which carries it to storage bins in the washer. This conveyer works on a 10-deg. pitch against the "loads," is 150 ft. long, and has a capacity of 800 tons in eight hours.

From the storage bin, which holds 700 tons, the coal is elevated and distributed to three Jeffrey-Robinson washers each having a theoretical capacity of 400 tons and an actual working capacity of about 350 tons. The clean coal from the washers is elevated into the washed coal drainage bins having a capacity of 800 tons, whence it is loaded into railroad cars and shipped for steam coal. The refuse is again elevated and fed by means of a

screw conveyer and a sluice box into two jigs each having a capacity of 20 tons in eight hours; these two jigs recover about 20 tons of sulphur nodules which are shipped to Great Falls and used at the smelters. The coking coal, on being dumped at the tippie, feeds into a conveyer similar to the non-coking coal, but with only 600 tons capacity, whence it is delivered to the coking-coal division of the washer.

The method of treating the coking coal is so complex that a description of the equipment only will be attempted here. The first floor consists of five tanks which act as temporary repositories for the refuse and different sizes of coal pending their elevation for retreatment or final disposal. On the second as well as on the third floors, there are 10 jigs, all of the Luhrig type. The second floor has a crusher and the third floor a crusher and screen, the latter sizing to over ½ in. and under ¾ in. The fourth floor has two 6x4-ft. screens and one 8x10-ft.; the latter having a capacity of 400 tons in eight hours and sizing the coal to over 1½ in., 1 in., ¾ in. and under ¾ in.

The elevating equipment consists of eleven elevators having a range of work from the first to the fourth floor. The building itself is of brick and steel throughout. One hundred coke ovens of the usual beehive type, 12 ft. in diameter, extend out from the washed coking-coal drainage bin, the coal being delivered to the ovens by means of a six-ton larry pulled by a horse.

Electrolytic Determination of Nickel

By V. P. DAVIS*

Dr. August Schumann, of Eisleben, has just published some results of analyses and experiments (*Zeits. f. angew. Chemie*, Dec. 18, 1908—2579) carried out under his personal supervision in which he confirms the inaccuracy of Professor Claisen's method for the quantitative determination of nickel by electrolyzing the double oxalate. Some new methods are detailed which Doctor Schumann considers entirely trustworthy. The work is yet unfinished, therefore full details of manipulation are lacking, except in the analysis of pure nickel salts; but certain facts seem to be definitely established.

The metal must "plate" on the cathode; that is, deposit in coherent form, not as "sponge" or "moss." Negative metals, such as copper, antimony and arsenic must be absent. The presence of iron, manganese and aluminum is permissible only in small amounts. Chlorides and nitrates, when properly dealt with, give perfectly reliable results, contrary to the present generally accepted opinion. The

best results are in every case obtained with a strongly ammoniacal electrolyte. The addition of soda pyrophosphate as recommended by Brand is an unnecessary complication, results with and without its use proving identical.

Weston's boric-acid method is applicable only when using a platinum dish or wire gauze as cathode. With a conical or cylindrical cathode the nickel deposited spongy and could not be weighed. Treadwell's recommendation, consisting in the addition of a small quantity of sulphuric or hydrochloric acid, to the electrolyte, is criticized as untrustworthy. Results by this method failed to check within allowable limits.

The obvious disadvantages of a strongly ammoniacal electrolyte have been met in part by the substitution of ammonium carbonate; though final report is yet to be had in this connection. An improvement in the cathode is the use of a piece of platinum wire gauze in place of the customary dish or cylinder. The gauze presents the advantage of lower first cost on account of its light weight, ease in cleaning, and the fact that it unfailingly deposits bright coherent metal. Faultless results are obtained with a low-current density and the addition of a certain amount of ammonium sulphate to increase the conductivity of the electrolyte. Following is a description of the analysis of nickel-ammonium sulphate: Electrolyte, 150 c.c. (including 40 c.c. ammonia); separation of electrodes, 1 c.m.; voltage, 6.14; temperature, 60 deg. F.; amperes, 0.37; time, 4 hours; Ni present, 0.1828 grams; Ni found, 0.1828 grams.

Osceola Mining Company

This company reports for 1908, with comparison to two previous years, as follows:

	1908.	1907.	1906.

Placer Gold Mining in Interior Alaska

The Fairbanks, Tanana and Koyukuk Districts Offer a Promising Field for Prospecting, Lack of Transportation Being the Chief Obstacle

EXCERPTS FROM A PRIVATE LETTER

Placer mining in its different forms is the principal industry of all interior Alaska. The production of gold in the Territory for 1906 was \$18,600,000; and for 1907, \$16,400,000, the decrease being due to labor troubles and the lack of labor. Half of the total amount produced in 1907 came from the Fairbanks district, but gold is being produced from the gravels in many places throughout Alaska. The number of places producing gold is increasing annually and I think will continue to do so for a long time to come. The staking of large areas by power of attorney has deterred prospecting a great deal, particularly in sections near producing camps. There are hundreds of square miles of territory, however, that has been neither prospected nor staked.

GENERAL CONDITIONS IN ALASKA

Poor transportation is the greatest obstacle to mining in the interior. Means of conveyance are controlled by one or two companies, practically to the exclusion of all others. Projected and partially built railroads from the vicinity of Valdez, on the coast, into the copper districts in southern Alaska will, when completed, no doubt be a great help to the Tanana valley and a large area in that vicinity. Were it not for the high price of equipment much ground which is now valueless would be productive. Such favorable conditions will no doubt be brought about in a few years. The Koyukuk country, on the headwater of the Koyukuk river, in which very rich discoveries have been made lately, gives promise of being a large producer in the near future. The Koyukuk river lies north of and flows in a course almost parallel to the Yukon river into which it empties about 600 miles from the mouth.

Good reports come from the Valdez Creek country, about 200 miles southwest of Fairbanks and about the same distance from Valdez. It empties into the Susitna river, which in turn empties into Cooks Inlet. It is a very inaccessible district and supplies are expensive. There are some very rich gravels on the rimrock and on benches in a few places, but on the creeks the prospectors have not reached bedrock on account of the water. There is no machinery in the district. Miners are bothered with large boulders in places I understand. The gold is coarse; \$1,000 was paid for a single nugget found in this district.

There is a great deal of coal as well

as copper in many parts of interior Alaska as well as on the coast. Prospecting is handicapped somewhat by conditions, by frozen gravel and by the fact that the country is generally covered with a growth of moss or tundra. This accounts largely, in my opinion, for the lack of quartz discoveries in the interior.

The total population of the interior of Alaska will hardly exceed 5000, and the small number actually prospecting, under conditions which make prospecting laborious and slow, indicates how much of Alaska still remains to be prospected. The drilling machines are working, mostly, for an interest in the ground they prospect. The interest usually given is one-half, and the number of holes drilled from 6 to 12 on claims of 20 acres, or about this proportion.

There have been some new discoveries of good pay ground lately on Engineer and Lower Goldstream creeks, also on Little Eldorado creek, both near Fairbanks. A few days ago I saw a pile of ten gold bars in the window of the bank in Fairbanks. They were the result of sluicing operations during the winter months.

It takes about 25 or 30 days for mail to travel from Fairbanks to the United States in winter *via* stage; there are two stages a week from Fairbanks to Valdez. In summer it takes a little longer *via* steamboat, to Dawson and White Horse. No outside mail comes in *via* Nome or St. Michaels.

METHODS OF MINING

The methods and costs of mining vary with conditions and locality. The methods in the region about Fairbanks where most of the gravel is from 50 to 300 ft. deep to bedrock are: Sinking shaft to bedrock, drifting along the course of the pay gravel and driving crosscuts from main drift to both limits of the deposit. The pay gravel is extracted by breasting out the crosscuts beginning at the farther limits of the drifts and working toward the shaft. The pay gravel is hoisted with as little waste as possible, and is sluiced for the recovery of the gold. The main drifts are usually carried about 200 ft. each way from the shaft and timbered. The crosscuts are seldom timbered, for in most cases the gravel is solidly frozen and usually permits of breasting without the use of timber, the work being carried on in two or more of the crosscuts as desired. Work in this case means

thawing the gravel, usually by steam, and extracting by pick and shovel. While extracting the gravel in the breast on one side of the drift, thawing is in progress on the other side. The steam point generally used for thawing is a piece of round hollow soft steel about 8 ft. long with a blunt hollow point of tool steel for piercing the ground, and a solid head of tool steel made strong enough to drive with a hammer. Steam is admitted through a pipe fitted laterally to the head. Hot water is, however, more frequently used for driving the points into the gravel and the thawing completed by means of steam. This has been found to be more rapid and satisfactory as a rule. The points are placed about 2½ ft. apart and require from 1 to 2 boiler capacity per point. In most places the points are left in the ground from 15 to 24 hours each thawing from 3 to 5 cu.yd. or more.

In many cases where a larger amount of ground is blocked out the points are left in the ground 10 or 12 hours and then withdrawn to be used elsewhere, the ground being allowed to "sweat" as they term it, thawing continuing for several hours after the points have been withdrawn, owing to the heat radiated from the thawed gravel.

Hot water hydraulicking by means of pulsometer or pumps of other types has been successfully used in some places and I think could be advantageously employed more generally.

After thawing, the gravel is removed by pick and shovel and carried by wheelbarrows or cars to the shaft, whence it is hoisted to the surface by buckets, generally attached to an automatic carrier or traveler which permits the dumping of the gravel directly into the sluice boxes, located 100 ft. or more from the collar of the shaft. In winter the gravel is conveyed to a dump under which sluice boxes have been placed, and is passed through the boxes in the spring when snow and ice begin thawing and water is available. Winter work is therefore somewhat more expensive. Gravel must average more than \$2 per cu.yd. of ground worked in order to pay a profit in drift mining. Wages are \$5 and board for miners, \$7 for engineers and mechanics, and \$10 for foremen.

OTHER METHODS

Open-cut mining is carried on in a few places where the gravel is shallow. The ground is stripped either by sluicing or

with scrapers operated with steam or horsepower. Sometimes the gravel is thawed by steam, occasionally by exposure to the sun, and frequently by running water over it, when water is available. In the latter case bedrock drains are usually constructed and some means of elevating tailings employed. The usual method for handling the gravel after it is thawed is either by shoveling into wheelbarrows carrying it to the bucket in which it is conveyed and dumped into sluice boxes, or by moving it directly to sluice boxes with scrapers. In the latter case a common plow is generally used for loosening the gravel.

Gravel deeper than about 20 ft. can usually be worked more cheaply by drifting than by open-cut methods, especially if the gold is concentrated at or near bedrock, which is the rule in the parts of the district that I have been over.

The best clean-up I personally know of, last year, was on Discovery claim, Cleary creek. The amount of gold recovered from the gravel in three days by ten men was a little more than \$22,000. I have heard of larger clean-ups and presume that the reports are true.

The methods generally in use could be improved, and costs could be materially reduced by the use of proper equipment. One reason why better equipment is not employed is because most of the ground is worked by leasers, or "laymen" as they are termed here, the amount of ground in each lease being small, from 100 to 500 ft. along the claim and, of course, extending to both side lines. The leasers in most cases are men with small capital; consequently they use only such equipment as is necessary. If they do find pay the amount of ground under lease is so small that expensive equipment is not justified. The locators of ground naturally desire a large number of leasers, for then the ground is prospected more quickly and the gold, if any, is recovered in less time.

A method of extracting gravel with some kind of mechanical device for digging and loading, instead of with pick and shovel, which is the universal practice, would, I believe, very materially reduce present costs. The average output per man with pick, shovel and wheelbarrow is about 9 cu.yd. delivered to the bucket at the shaft for a 10-hour shift. The Park automatic loader and conveyer, manufactured by the Railway Materials Company, Chicago, it is claimed, handles from 1 to 3 cu.yd. per minute. I saw one in operation at the Gunnison tunnel in Colorado and it certainly handled muck very rapidly. These machines do not require a track, and I think would be easily adapted for the work described. The lack of any kind of undercurrent or mercury in connection with the sluice boxes also tends to reduce the amount of gold recovered. The methods here described will, I think, apply in general throughout Alaska.

The cost of thawing ground, generally, is about 30 or 40c. per cu.yd. Some dredges claim to be handling thawed gravel for 10c., but I am inclined to think it will be nearer 20c. for general practice, except under favorable conditions, judging from what I have seen.

DREDGING

With regard to dredging, the practice is much the same as in the United States; the costs, however, must be twice as high. Frozen gravel is the greatest obstacle in dredging. The short working seasons also hinders the work. But in spite of these unsatisfactory conditions, I believe there is a big field and many encouraging opportunities for dredging in Alaska. The many rivers and sloughs traverse thousands of miles of territory a large portion of which is known to be gold bearing. The numerous bars in the beds of the streams are never frozen and could be easily dredged if the quantity of gold justified the expenditure. In very few instances have they been prospected, and then as a rule only by the crude appliances of the average prospector, and not with a view to dredging.

Last summer I panned some of the bars near here and seldom failed to get colors although the gravel panned was taken from the surface to a depth of about 12 in. and from immediately beside the river when the water was low. In coming down the Yukon I noticed in a few places, sluice boxes or rockers on a few of the high bars. Prospecting for this character of dredging ground could best be carried on in the winter.

PROSPECTING WITH MACHINE DRILLS

Any type of drilling machine, such as the Keystone, Star, Dempster, Cyclone, Empire, or even a spring-pole drill operated by hand would be adaptable for this kind of work. Dempster drills could be set up on the ice which covers the rivers in winter and the work could thus be carried on much more rapidly and to better advantage than from a scow. They may be moved from place to place quickly. There are a few of these drills here in use for prospecting the gravels. They do not require any casing when drilling in solidly frozen ground.

The greater part of the overburden is a very fine sand, and in this the drills make as high as 75 ft. in a day of 10 hours. In the gravel it ranges from 5 to 20 ft. per day. Work is carried on all winter. These machines complete weigh 2 or 3 tons and are cumbersome to move for the country is generally covered with "nigger heads" (hillocks or big bunches of grass) and is practically impassable for any kind of vehicle. For inaccessible country except where roads are built, the Empire drill is best and cheapest; also for prospecting gravels not more than 100 ft. deep. The heavier sizes weigh

about 1600 lb. and the lighter ones (for gravels up to 50 ft. deep), about 1000 lb. They can be taken apart and made into packs of 75 lb. The machine can be operated by hand or by horse or steam power. The others named cannot be operated except by steam, or gasoline.

THE SPRING-POLE DRILL

I have not seen or heard of the use of a spring-pole drill in Alaska although drills of this kind are frequently used in the United States. The spring-pole drill consists of a piece of drill steel, usually about 2½ or 3 in. in diameter of bit weighing about 150 lb. and fastened by means of a rope to the end of a pole which sustains the weight. One man, by pulling down on the rope, allows the bit to strike the ground, thus gradually cutting and disintegrating it so that it can be taken out by means of a sand pump.

An outfit of this kind does not weigh more than 350 lb. and can be operated to advantage to a depth of 50 ft. if not deeper. Such a machine would be invaluable to the prospector here providing he had a fair knowledge of drilling with any of the power machines named. It would permit of his prospecting ground where living water is encountered, which is impossible with the equipment of the ordinary prospector in Alaska. Living water has been encountered in some parts of practically every camp that I have heard of in Alaska. Such gravels, the conditions being favorable, could be dredged at good profit.

Investigations along this line will I believe result in the installation and operation of many dredges throughout interior Alaska. The type and size of the dredges to be employed will be governed by conditions. A small dredge with an estimated capacity of 500 cu.yd. per 24 hours was constructed at Fairbanks last fall at a cost of about \$6000. The machinery was made by the Byron Jackson Company, of San Francisco, and consists essentially of a digging wheel which discharges through bottomless buckets into a 6-in. suction pipe connected with a centrifugal pump mounted on a barge at water level. Gasoline power is used for operating it; the requirement being 16 h.p. It was in operation for a day or so and it is claimed, worked satisfactorily.

A knowledge and the careful consideration of existing conditions is essential to the successful construction and operation of dredges in Alaska. This has been thoroughly demonstrated by the many unsuccessful installations on Seward peninsula. There are dredges now operating successfully and at a profit on Seward peninsula, however, and the successful ones are not all of the same type either. I have heard of dredging ground in the Forty Mile district southeast of Fairbanks upon which some dredges are operating. I understand there is also good

ground for dredging northeast of Fairbanks, in the Birch Creek district near Circle on the Yukon. Mr. Barnette, a banker and mining operator of Fairbanks, has invested rather heavily in the Birch Creek district this fall and winter and has a drill of the Keystone type prospecting ground with a view to dredging. One hears of ground in almost any of the districts that may possibly be suitable for dredging.

WINTER PROSPECTING

In Alaska the greatest amount of prospecting is done in the winter. A large proportion of the prospectors work in the mines in the summer and prospect in the winter. They travel over the frozen streams in winter with sleds. In the summer poling boats are used, long boats of the canoe type, pushed along by means of a pole. In going down stream nothing is needed except an oar, with which to guide the boat.

Ice begins breaking up about the first or middle of May, and in a few days after the ice begins to break up the rivers are clear. Summer advances rapidly after the ice goes out. Mush ice begins to run in the rivers about Oct. 15 or 25, and in a week or two the rivers are frozen over. There are usually no frosts until about the first or the middle of September. Many vegetables are raised in Alaska. Potatoes raised in the territory sold for 10c. per lb. last fall. Tomatoes, celery, carrots, turnips, etc., were also on the market.

PROSPECTING BY MEANS OF SHAFTS

Sometimes the thawing of the ground is accomplished by means of a wood fire, or with rocks heated and thrown down the shaft and covered with moss. When this method is employed several holes are usually thawed simultaneously. The method is very slow, from a few inches to as much as a foot in depth being thawed in a day. The more common device is the steam point, the usual prospector's outfit consisting of a small boiler weighing about 250 lb. and costing about \$250. A couple of points with 1/2-in. pipe and a short length of steam hose, picks, shovels, etc., complete the equipment. Hoisting is usually done by hand. The complete outfit, including provisions for a season, can usually be loaded in a poling boat and handled by two men.

In winter prospectors frequently use dog teams if game is plentiful in the districts to be prospected. Otherwise they are too expensive to keep. As a rule it is not necessary to timber prospect shafts. When water is encountered, work is usually abandoned even though the prospect is fairly good, which is frequently the case.

The common method in Alaska for estimating values is by the quantity per pan, from five to seven pans being reckoned as a cubic foot.

Placer claims are usually staked 660x 1320 ft. except in association claims which consists of 160 acres.

Regarding the prospecting of wet gravels, I have seen but one drilling machine equipped with casing which is necessary in order to drill ground of this character, and this machine was owned by Mr. Barnette and was on the way to the Birch Creek district for the purpose of prospecting shallow dredging ground. Drilling machines in the neighborhood of Fairbanks abandon the hole when they strike thawed gravel, for the loose ground caves in, and attempts to drill without casing nearly always results in the loss of a string of tools, which are very expensive and hard to replace. The hole drilled by most machines is 6 in. in diameter, although 4 in. is sometimes used.

An outfit, including a season's provisions and a spring-pole drill which can be operated by one man, will cost in the neighborhood of \$1500. One thousand dollars a year would about cover expenses. A larger allowance would permit of visiting a greater number of districts traveling by regular passenger boats operated by the transportation companies, and this might be best if securing property by bond and option were considered of the first importance.

EXPERIENCES IN THE KOYUKUK DISTRICT

Since beginning this letter I have had an interview with a man who has just arrived from the Koyukuk district. He had been in that section three or four years and brought out \$3000 or \$4000 in gold dust. He said the best find so far made is on Olson's claim, Nolan creek, at a depth of 140 ft. and on bedrock. Three men took out \$125,000 above expenses in about three months, one pan taken from in front of a ridge in bedrock being worth \$1500. Two claims above this on the same creek \$65,000 was taken out in the season, but the gold came mostly from gravel to a depth of 12 or 15 ft. from surface. He does not think they reached bedrock at all.

In one place in which he worked on Emma creek, eight miles above Nolan creek, they drifted in on good pay gravel until they struck a hard cemented conglomerate which they could not work although they used some powder. He said they could see some gold in the conglomerate. He also stated that they sometimes found in the sluice boxes gold entirely covered with a white crust or coating, probably carbonate of lime. He stated that bedrock was sometimes limestone, but more generally a schist.

The gulches were frequently narrow and steep. They worked on lease in one place where they shoveled gravel as deep as 3 ft. below water, never reaching bedrock except in a few places; the gravel produced good pay. There is very little machinery of any kind in the district, the

transportation companies claiming that they could not get shipments in during the fall. He stated that wet ground on one or two creeks that he had panned prospected well, but that the gravel was probably deep and would be expensive to pump; it might be dredged, but he knew nothing of dredging methods.

There were no drilling machines of any type in the country. The number of men in the district was about 200. To anyone with little money he would recommend the country as a good prospecting field. He said that he got \$18.20 per oz. for his gold at the bank after paying a 2 1/2-per cent. fee for exchange or purchase, which is charged by all banks in Fairbanks, when purchasing gold dust. The Olson strike, was described in the Seattle papers in July, 1908, on the arrival of an Episcopal minister from the Koyukuk. The gold from this district is coarse.

OPPORTUNITIES IN THE INTERIOR OF ALASKA

To those who will work and have a knowledge of how to do so intelligently and who are not afraid of some hardships, Alaska offers many inducements, one in particular being the prospecting of wet gravels. This, I believe, can readily be done with drills of almost any type. A determination of the gold content and depth and a rough estimate of the flow of water would indicate whether the ground could be worked profitably by dredging or otherwise.

The cost of a machine drill is about \$2500, and an equipment of this kind is expensive to operate and move except for very short distances, as for instance from one hole to another on a 20-acre claim. Engineers' wages are \$7 per day and board, and of helpers, \$5 a day and board. Wood and water must usually be hauled and this requires the services of another man and sometimes a horse for a portion of the time. With a spring-pole drill there would be no additional expense above those necessary with present methods. Of course a spring-pole drill will not drill nearly so fast as a machine but it requires much less time to move, set up and take down. A spring pole can usually be cut where the hole is to be drilled. Wet gravels can be prospected if casing is used, as readily as with machines.

In making concrete mortar-block (C. E. Parsons, *Bull. No. 50* I. M. and M.) the concrete should be well tamped as well as thoroughly mixed, and if possible all the cement should be put in place in one day. Generally the proportion of cement is increased near the top of the block.

In Austrian mines, according to the *New Zealand Mines Record*, underground rescue chambers are provided. These are made to hold 50 men, and besides having pure oxygen piped into them, are stocked with provisions, first-aid supplies and rescue apparatus.

The Mines and Mills of Tonopah, Nevada

The Gold-Silver Mines Have Been Handicapped by Lack of Transportation; Cyanide Mills Now Treat the Low-Grade Ores

B Y G. E. W O L C O T T*

In the last few years the Tonopah mining district has been rapidly taking a place of importance among the silver-producing camps of the United States. Recent strikes in the camp promise a steady and probably increased production. The principal producing properties of the district are, in the order of tonnage produced, as follows: The Tonopah Mining Company, the Montana-Tonopah Min-

ing ore of a comparatively high grade could be mined at a profit, but with the completion of the milling plants at Millers of the Belmont and Tonopah companies and that of the Montana-Tonopah at Tonopah ore of much lower grade can be worked. The town of Millers is situated on gently sloping ground 11 miles from the mining center. Water is obtained in ample quantities for milling purposes at a

Overhead stoping is the rule, the machines mostly in use being of the air-hammer type, which have here almost entirely replaced piston machines for overhead work. Piston machines, 2½ in., are mostly used for drifting and sinking. The ore consists chiefly of quartz carrying only a small percentage of sulphides, with the silver mostly in the form of proustite and pyrrargyrite. The pro-

TONOPAH FROM BROUGNER HILL

ing Company, the Tonopah-Belmont Mining and Development Company, the MacNamara Mining Company, the Midway Company and the Tonopah Extension. The Jim Butler, West End and North Star mines have been rather intermittent producers. The approximate total monthly production is at present about 25,000 tons with an estimated value of more than \$500,000.

Until within the last few years only

depth of about 35 ft. and is pumped to the mills from plants situated a short distance below them.

METHODS OF MINING

None of the Tonopah mines has been troubled with water, although the deeper shafts have reached a depth of 1200 ft. and more. The Mizpah shaft of the Tonopah Mining Company is at present being sunk to a greater depth than has hitherto been reached.

portion of silver to gold is about 100 to 1 by weight or 5 to 2 in value. A part of the ore requires very little sorting, and some is milled without any sorting at all; the proportion of waste rock in the ore is usually comparatively small. Veins vary in width from a few inches to as much as 30 ft. or more, and are usually only slightly inclined from the vertical.

The Tonopah Extension is the only mine which is shipping any amount of ore to outside points. The ore as milled has

*Mining engineer, Tone, Cal.

an average grade of from \$20 to \$25. All of the principal producers of the camp are situated in the saddle between Oddie and Brougner hills and upon the sides of these hills.

MILLING

The mills of the district include the

6000; Montana-Tonopah, 4700. Assuming an average grade of \$22 and an extraction of 90 per cent., this gives a yearly production of \$5,749,200.

The Montana-Tonopah mill has recently been described. This plant is situated at the company's mine on a side-hill site, and

stamps; but at present these are not in use, the entire crushing being done by stamps. The batteries crush through a 35-mesh screen and run in units of 20 stamps, driven by 50-h.p. electric motors. The stamps are arranged so that 10 stamps can be started at a time. The

SAND WHEEL, DESERT MILL

LEACHING TANKS, DESERT MILL

MINE AND MILL, MONTANA-TONOPAH COMPANY

DESERT MILL, MILLERS, NEVADA

BELMONT MILL, MILLERS

ZINC BOXES AND CIRCULATION TANKS, DESERT MILL

Belmont mill, having 60 stamps; the Desert mill of the Tonopah company, 100 stamps, and the Montana-Tonopah with 40 stamps. These three mills are treating in the aggregate about 24,200 tons per month, the tonnage being divided as follows: The Desert mill, 1350; Belmont,

less power is required for elevating purposes than at either of the other two mills. The plant is well constructed throughout and has been treating ore at an average cost of less than \$4 per ton.

The Belmont mill was first constructed to use Huntington mills following the

same arrangement is used at the Desert mill. The flow sheet of this mill is much more complicated than that of the Belmont or the Montana-Tonopah mills. The essential difference between this mill and the Belmont is that stage grinding is employed by the use of Huntington

mills following the stamps. The stamps crush to 10 and 12 mesh, and the Huntingtons to 30 mesh. The middlings from the Wilfley tables are also reground in a Huntington mill. With the exception of this feature the practice is essentially the same as at the Belmont plant.

At the Belmont mill the crushing is done in a solution containing 45 lb. cyanide per ton. In the sand-leaching tanks 300 lb. additional cyanide is used for 140 tons of ore, and in the slime-agitation tanks, 300 lb. for 80 tons of ore. The total cyanide consumption is 3.2 lb. per ton. To prevent the reprecipitation of silver in the form of sulphide, $\frac{3}{4}$ lb. lead acetate is added for each ton of ore; at the Desert mill 1 lb. is used for three

agitators for a period of 72 hours, steam and compressed air being admitted at the bottom of the tanks for heating and oxidizing. It is aimed to heat the pulp to about 90 deg. and steam is generated especially for this purpose. A lowering of temperature results in decreased extraction. Sands and slimes are produced in the proportion of 55 to 45.

From the slime-storage tank the slimes go to two Butters filter tanks containing 60 leaves each, the filters being 5x10 ft. The original filters had a filtering medium consisting of cocoa matting inside heavy filtering cloth. These proved unsatisfactory because of the clogging of the matting by lime, and are being replaced by homemade filters using the original

provided for the treatment. The filters are also tested to detect and repair any leaks that may develop.

Precipitation at both the Belmont and the Desert mills is by zinc shavings cut at the plant. The zinc precipitates are dried and melted direct, without any preliminary acid treatment. At the Montana-Tonopah mill precipitation is by means of zinc dust, the precipitates being sent to the smelter.

CONCENTRATION AND COSTS

In the concentrating department one ton of concentrates is obtained from 100 tons of ore, the concentrates carrying an average of 600 to 700 oz. silver and about 8 oz. gold. No attempt is made at any

FLOW SHEET, BELMONT MILL

tons of ore in the sand tanks, and 1 lb. for each ton in the slime tanks. The sands are first collected in dewatering tanks, where they are drained by means of a suction pump and then transferred by belt conveyors to the leaching tanks.

The treatment in the leaching tanks occupies 14 days. At the Desert mill a Blaisdell excavator is used for emptying tanks, while hand labor is employed at the Belmont. In each case the tanks are emptied by center-discharge gates upon belt conveyors.

SLIME TREATMENT

The slimes are agitated by mechanical

frames. Instead of cocoa matting, wooden strips, $\frac{1}{2}$ in. square and placed 2 in. apart, are used. These give better satisfaction than the original leaves and give a greater filtering capacity.

The treatment in the filter vats takes a little more than three hours. Slimes are introduced for about 1 1/4 hours; the pulp is then pumped back to the storage tanks, the cake being held on the leaves; and weak cyanide solution is drawn through about one hour. The time taken in charging, discharging, etc., brings the total up to more than three hours. The filters are given a treatment in dilute hydrochloric acid every 15 days, separate tanks being

of the mills to treat their own concentrates, although some experimental work has been done with this end in view.

At all three of the mills a bullion recovery of approximately 90 per cent. of both silver and gold is claimed.

At the Belmont mill the cost of treatment for the year 1907 was given as \$7.825 per ton. While authoritative figures could not be obtained at the time of my visit, this figure is generally supposed to be higher than the actual cost. The Belmont and Desert mills at first generated their own power by steam at a rather excessive cost. This has since been greatly lowered by the use of power

FLOW SHEET, MONTANA-TONOPAH MILL

generated near Bishop, Cal., and supplied at the mills at a rate of from \$11 to \$12 per horsepower-month.

At the Belmont mill the crushing is in one operation with subsequent separation of sands and slimes; at the Desert mill stage grinding, with Huntington mills following stamps and separation of sands and slimes, is used, while at the Montana-Tonopah entire sliming of the product with the use of tube mills is practiced. It would be interesting to compare the milling costs in the three cases, but at present sufficient data are not available.

Short Talks on Mining Law— XIII

By A. H. RICKETTS*

A patent for land claimed and located for valuable deposits may be obtained by any person authorized by law to locate a mining claim and who may have complied with the terms of the mining act. That act provides what steps are necessary, and the Land Department may be said to regulate the proceedings for, and to finally determine the right to the patent.

The Land Department (including in that term the secretary of the interior, the commissioner of the General Land Office and their subordinate officers) constitutes a special tribunal, vested with judicial power to hear and determine the claims of all parties to the public lands which it is authorized to dispose of, and also the power to make conveyance of the government to the parties it declares are entitled to it.

The manner for obtaining a patent for either a lode or placer claim, whether for a single claim or for a number of contiguous lode or placer claims, that is, those which touch sides, lie alongside of, are adjacent or adjoin, with or without a mill site included therein, or for a mill site only, is substantially similar, except that all lode claims and mill sites must be officially surveyed for patent; and that coal lands can be entered only after survey and by legal subdivisions under special regulations. But one entry of coal or saline lands and possibly of a mill site by any person, association of persons, or a corporation, is allowed by law. Placer claims which have not been located according to the rectangular subdivisions of the public surveys must be officially surveyed. Claims which constitute one or more contiguous 10-acre lots of a 40-acre tract, may be subdivided into squares with lines at right angles with the lines of such surveys, and can be appropriately described as, say, the northeast quarter of the northeast quarter of the northeast quarter of a certain section, range and meridian, are not subject to such survey. If the claim be all placer ground, that fact must be stated in the application for

patent and be corroborated by the affidavit of other persons. If of mixed placers and lodes, it should be so set out, with a description of all known lodes situated within the boundaries of the placer claim. Known veins or lodes included within such area must, if claimed by the applicant, be specifically applied for, or his right thereto will be waived. Where an official survey of a placer claim is made, the Land Department requires the deputy making the survey, to file a verified, corroborated report, containing such data as, for example, the proximity of the claim, the centers of trade or residence, the amount of vegetation, the *locus* and size of streams, etc. Such report must be made a part of the application for patent, or as oddly expressed in the rules of that department, be "included in the oath of the applicant."

APPLICATIONS FOR PATENT—THE SURVEY

The initial step in an application for either a lode or a mill site, or both combined, is the filing with the United States surveyor general of the district in which the same may be situated, of a written application, requesting an official survey of the claim by a deputy United States mineral surveyor, nominated therein by the applicant, who has no interest in the claim and whose charges must be paid for by the latter. The courts are not in accord as to whether the deputy is the agent of the applicant or not. Contemporaneously with the application there should be filed therewith a copy of the location notice certified by the officer in charge of the records where the same is recorded, or a statement showing sufficient reasons for its absence. Also a certificate of deposit, issued by the proper United States sub-treasurer for the amount which may be required by the surveyor general in the preparation of the plat and field notes of the survey in his office. Thereupon such deputy receives an order of survey from such officer. The survey should be actual, and should be made in conformity to the rules of the Land Department, of which the surveyor-general's office is an integral part. When making the survey the end lines of the location may be straightened within the boundary lines of the claim. Errors in the survey occurring through the carelessness or negligence of the deputy, must be corrected by him at his own expense. His failure to comply with instructions from the department to do so within a specified time is ground for his suspension or removal from office.

The deputy is required to transmit to the Surveyor General his field-notes, a preliminary plat of the survey, indorsed with his approval, together with a statement of the value of the labor done or improvements made upon the claim, or if done upon one of a group of contiguous claims, that the work so done or the improvements made tend to the development of all the claims within the group and equals in the aggregate the statutory ex-

penditure of \$500 upon each of them. These data are retained in the office of the surveyor general, who, if the same are correct, approves thereof and causes copies of the same to be made in his office and sends to the applicant copies of the plat for posting upon the property, and also for filing in the local land office, together with the field-notes, as a part of the application for patent. This officer also sends a copy of the plat to the general land office at Washington and another copy to the local land office. It is usual for him to certify upon the plat that the statutory amount necessary to obtain a patent has been expended upon the claim (not upon the mill site). But this is not essential as such an expenditure may be made after survey and before the expiration of the period of newspaper publication and the certificate filed thereafter. This certificate of expenditure may be attacked in the land department before patent issues. Otherwise, it is conclusive of the facts stated therein. The equivalent of this certificate is an affidavit, where the application is for a placer claim which is not subject to official survey, made by two or more disinterested witnesses that not less than \$500 has been expended by the applicant or his grantors upon the claim, located by legal subdivision.

The next step in the proceeding is for the applicant to post a copy of the plat in a conspicuous place upon the claim and also one upon the mill site, if the application includes such, together with a notice of intention to apply for a patent. Both must be posted in such a way that they can be readily examined by any person desiring to do so. This posting must be done in the presence of two credible witnesses, who must make affidavit of such posting. This affidavit, which should state the date and place of posting, and contain a copy of the notice posted must be filed with, or before, the application for patent is filed.

PROCEEDINGS IN THE LOCAL LAND OFFICE

What may be termed the "application papers," and which should be filed say, contemporaneously in the proper land office, consist of the following documents:

1. The said affidavit of posting the plat and notice upon the claim.

2. An application under oath of the claimant, or his attorney in fact or agent thereunto duly authorized, which should show, as clearly as possible, the facts constituting compliance with the requirements of the law, the origin of possession and the basis of the claim for the patent. If the application is for saline lands there must be incorporated in the application a statement that the applicant has never, either as an individual or as a member of an association, located, applied for, entered or held any other saline lands. If the party applying for patent does so as a trustee, he must fully disclose the nature

*Member of the San Francisco Bar.

of the trust, the names of his trustees, and furnish satisfactory proof of the citizenship of himself and of them.

3. Evidence of the citizenship of the applicant, which, if a natural person, should be given by his affidavit; if an association of persons, by the affidavit of each of them or of an authorized agent or attorney in fact made upon his information, or upon his information and belief; or if a corporation, by a certified copy of its articles of incorporation.

4. A duly authenticated copy of the authority of the attorney in fact or agent to apply for the patent, which in case of an individual or association may be by letter of attorney, or if the claimant be a corporation, by a copy of the resolution appointing him for that purpose, taken from the minutes of the meeting of the directors of the corporation, at which he was appointed, and certified to as correct by its secretary, under the seal of the corporation.

5. A copy of said plat and field-notes given by the surveyor general to the claimant.

6. A duly certified copy of the location notice and an abstract of title of the property complete to the time of filing the application, certified by the custodian of the records, or by a duly authorized searcher of records, or an abstract maker, who must certify that no conveyances affecting the title of the claim appear of record, other than these set forth in the abstract. The abstract may be in the usual form of such a document. That is to say, instruments usually abbreviated in such a work, may be abbreviated therein.

OTHER REQUIREMENTS

In the event that the records may have been destroyed, an affidavit by the claimant, supported by the affidavit of any other person cognizant of the facts relative to the location, occupancy, possession, etc., should be filed with the application. When an applicant bases his right to a patent upon the statute of limitations, he is not required to file any evidence of location, copies of conveyances, or abstracts of title, as in other cases; but he is required to furnish a duly certified copy of the statute of limitations affecting mining claims in the State or Territory within which the claim may be situated, together with his affidavit, giving a clear and succinct narration of the facts as to the origin of his title, and likewise as to the continuance of his possession of the ground covered by his application; the area of his claim, the nature and extent of the mining that has been done thereon, whether there has been any opposition to his possession or litigation with regard to his claim, and if so, when the same ceased; whether such cessation was caused by compromise or by judicial decree, and any additional fact within the claimant's knowledge having a direct bearing upon his possession, and *bona fides*, which he may desire to submit

in support of his claim. Thereafter the proceedings are the same as in other cases, excepting that the statement of facts as to the origin of the title of the applicant must be corroborated by the affidavit of one or more disinterested persons.

If the locators are the applicants for patent, they should state in their application, if such be the fact, that they have disposed of no interest in the claim.

Transfers made after the filing of the application will not be considered, but patent will issue in the name of the applicant, except when he is defeated in an adverse suit, or the protest of a co-owner may be sustained; but where the applicant is known to be dead prior to the submission of the final proofs and payment for the land, the register's duplicate receipt will issue in the name of the applicant's heirs and patent issued in conformity thereto.

Generally, all affidavits required in these proceedings may be verified before any officer authorized to administer oaths within the land district wherein the claim may be situated, as, for instance, a notary public within the county for which he is appointed, whether such county is wholly or partly without such district. In coal-land applications each application, declaratory statement and affidavit must be verified before the register or receiver in the land district wherein the lands involved are situated. All affidavits made outside the proper land district are insufficient and proceedings based thereon are void and patent cannot be obtained thereon. The exceptions to the rule are, that where the applicant resides or the adverse claimant resides, or at any time being beyond the limits of the district wherein the claim is situated, he may make any oath or affidavit required for proof of citizenship or to the adverse claim before the clerk of any court of record, or before any notary public of such State or Territory.

7. An agreement of the publisher to hold the applicant for patent alone responsible for charges of publication of notice.

8. A notice for publication and one for posting in the local land office, embracing all the data given in the notice posted upon the claim and indicating the *locus* of the claim by giving the connecting line, as shown on the field notes and plat between a corner of the claim and a United States mineral monument or corner of the public survey. Also stating the boundary of the claim by courses and distances, and the names of the bounding claims, if any. If this notice is declared insufficient by the land department, the application is defective, and the proceedings from that point must be commenced anew.

Where the application embraces a mill site there must also be filed an affidavit of two or more persons capable from acquaintance with the land to testify understandingly of its non-mineral character.

If no reason appears to the local land offi-

cers for rejecting the application the register orders publication of notice of such application for 60 days in a newspaper published nearest to the claim. The time for filing an adverse claim is not enlarged by the fact of excessive newspaper publication, nor by stipulation between the parties. During the period of publication, the plat and notice must remain posted on the claim, and during the same period the register must keep a copy of the notice posted in the land office.

If the application should be rejected by the local land officers, they must give their reasons therefor, and allow the applicant 30 days for an appeal to the commissioner of the General Land Office at Washington, from whom an appeal lies to the secretary of the interior.

If no adverse claim is filed, the applicant, after the said period of newspaper publication, or after the adverse claim is determined if one be filed, must within a reasonable time thereafter file the following additional papers:

9. Affidavit of the publisher that the said notice was published for the statutory period.

10. Affidavit of the claimant, that both the said plat and notice remained conspicuously posted upon the claim during the period of such publication.

11. Affidavit of the claimant showing what fees and charges were paid to the register and receiver, to the deputy for the survey of the claim for publication of the notice, and for the land embraced in the claim.

12. Written application for purchase from the Government of the property, accompanied by a sum equal to \$5 an acre, and each fractional part thereof, for a lode claim and mill site, or for a known lode within a placer claim and \$2.50 for each acre and each fractional part thereof embraced within a placer claim.

Thereupon the receiver of the land office issues a "duplicate receipt" to the applicant therefor. This instrument is sometimes called "final receipt," or "certificate of purchase." After its issuance further annual expenditure on the claim is not required, unless such receipt may have been procured by fraud.

WHEN PROCEEDINGS ARE SUSPENDED

The patent proceedings may possibly be interrupted by the filing of an adverse claim or a protest. The difference between an adverse claim, which is provided for by the mining act, and a protest, which is provided for by the rules of the Land Department, is that the first named must be filed within the 60-days' period of newspaper publication by one, or the heirs of one having a direct interest, or some right in the land, or some part of it, adverse to the applicant, and must be followed by an action commenced in a court of competent jurisdiction within 30 days thereafter; whereas a protest may be filed at any time before the actual

issuance of the patent by a person who appears as a friend of the Government in the proceedings, or in aid of the establishment of his equitable right in the premises. The grounds of a protest may be the non-citizenship of the applicant, or some fraud, lack of good faith, or failure on his part, in regard to any of the essential requisites to entitle him to a patent; or that the protestant is a claimant of a present interest and is surreptitiously excluded by the applicant from the application for patent. In the latter case, if suit is brought, the Land Department delays the issuance of patent until the courts have determined the rights of the respective parties, although there is nothing in the law requiring it to do so, and ordinarily proceedings on a protest are confined to the Land Department without right of appeal in the absence of a present interest.

By the terms of the mining act, the filing of the adverse claim suspends all proceedings in the Land Department, except the publication and posting of the plat and notice upon the claim and the filing of proof of each thereof, until the adverse claim is finally determined by the court, or is adjusted between the parties thereto, or the same is waived.

Waiver may be evidenced by a failure to commence suit within the statutory time, or by filing in the records of the court a statement or stipulation of the plaintiff that he abandons his case, or waives his claims, or by an instrument, signed by him and duly authenticated, stating that he has sold his interest to the other party, or by his failure to appear at the trial. Where an adverse claim has been filed, but no suit commenced against the applicant for patent within the statutory period, a certificate to that effect by the clerk of the State court having jurisdiction in the case, and also by the clerk of the Circuit Court of the United States for the district in which the claim is situated, are required by the Land Department. If suit has been commenced upon the adverse claim, a relinquishment, or other evidence of abandonment of the adverse claim will not be accepted by the Land Department, but the case must be terminated and proof thereof furnished by a certificate of the clerk of the court, to that effect, or by a certified copy of the judgment roll.

The applicant for patent waives his right thereto by failing to prosecute his application to completion by filing the necessary proofs and making payment for the land within a reasonable time after the expiration of the period of publication of notice of the application, or after the termination of the adverse proceedings.

THE ADVERSE CLAIM

An adverse claim is limited to the determination of surface conflicts arising from independent conflicting locations of the same ground by adverse mineral

claimants, or between a mineral claimant and the owner of a mill site, or possibly where the same land may be claimed under different laws, as for example, the owner of a town lot may adverse an application for a mining claim. It does not extend to controversies between co-owners claiming under the same location or title.

An adverse right is lost if not made the subject of an adverse claim, and the latter is nullified if not followed by suit commenced and prosecuted with due diligence. An adverse right cannot be the subject of a protest or *vice versa*.

The courts have specifically found* that the following holders of rights in a mining claim are not compelled to file an adverse claim to protect their respective rights: Co-owners, easement-holders, lien-holders, a mining claimant as against an application for a town-site patent, the owner of a known lode against an application for a placer patent not including such lode therein, a senior patentee, and in some cases a tunnel claimant.

The adverse claim must be upon oath of the adverse claimant, or his or its duly authorized agent or attorney in fact, cognizant of the facts stated. It must show the nature, boundaries and extent of the adverse claim and be followed by suit brought within the statutory period and prosecuted to final judgment unless otherwise disposed of.

The nature, boundaries and extent of the adverse claims are shown by the filing in the local land office of the following papers:

1. A plat showing the adverse claimant's entire claim, its relative situation or position with the one against which he claims and the extent of the conflict, except that when both claims are claimed by legal subdivisions, no survey or plat is necessary. If not so held it is preferable to have such plat made from an actual survey by a deputy mineral surveyor and its correctness officially certified thereon by him, but this is not essential, nor does the matter have to pass through the surveyor general's office.
2. An affidavit fully setting forth the nature and extent of the interference or conflict and whether the party claims as a purchaser for a valuable consideration or as a locator. If the transaction was a verbal one, the circumstances attending the purchase, the date thereof, and the amount paid are to be stated. This should be corroborated by the affidavit of one or more witnesses, if any were presented at the time.
3. A duly certified copy of the location notice from the office of the proper county recorder.
4. A duly certified copy of the conveyance to the adverse claimant, or an abstract of title, as in the case of an application for patent.
5. If the "adverse" is filed by an agent

or attorney in fact proof of his authority, as in the case of an application for patent.

Upon the filing of these documents and the payment of the requisite fee, the officers of the local land office give notice of such filing to both parties and that it is necessary for the adverse claimant to bring suit thereon within 30 days after such filing, to determine the right of possession to the land in dispute.

The adverse suit may result in a judgment for none of the parties thereto, or in a judgment in favor of the plaintiff or of the defendant, or there may be as many different judgments affecting different parts of the claim as there are successful parties to the litigation.

To complete the patent proceedings the successful party to the litigation is required to file in the local land office a duly certified copy of the judgment roll, except that where such suit has been dismissed a certificate of the clerk of the court to that effect or a certified copy of the order of dismissal will be sufficient, together with the proofs required where no adverse claim has been filed. In case he be an adverse claimant, he must also file therein:

1. A certificate of the surveyor general that the requisite amount of labor has been done or improvements made and the description required in other cases.
 2. A written application to purchase, and payment as set forth in No. 12 hereof.
- Whereupon, a "duplicate receipt," or certificate of purchase is issued, provided the local land officers are satisfied that the proper proofs have been filed, in which event the whole proceedings and the judgment roll are certified by the register to the commissioner of the General Land Office, and patent issues to the claimant for the claim as applied for, or for such portions thereof as the applicant or the adverse claimant shall appear from the judgment of the court to possess rightfully. That is, patent issues to the respective parties, according to their respective rights, provided, that the officers of the General Land Office are satisfied that patent should issue at all, as the judgment of the court is conclusive only between the parties as to the right of possession and not as between them or any of them and the Government in the matter of the passage of the fee-simple title. Hence, the Land Department may require an amendment of the application or of some one or more of the papers comprising the same, or order a hearing in the local land office to determine the character of the land or order a segregation survey thereof; or possibly it may cancel the certificate of purchase, and perhaps upon proper proceedings had, declare the land restored to the public domain. A subsisting "duplicate receipt," is equivalent as far as third parties are concerned. It is free from collateral attack.

Reclaiming the Inclined Hoistway at Mine 21

By GUY C. STOLTZ*

Mine 21 at Mineville, N. Y., a magnetite property of the Port Henry Iron Ore Company, was at first (1846) worked on the outcrop by the room and pillar method the ore being hoisted on a double-track 57-deg. incline trestled throughout and following in general the dip of the footwall. As the workings became deeper, the management, in order to secure the

of extraction from the open pit was, however, offset by the annual expense incurred in handling the large volume of water, precipitated in the pit in the form of rain and snow.

After the larger pillars had been mined out, the pit method was abandoned, sinking was resumed and the mine was again worked on levels, room and pillar fashion, and a roof of ore was left to protect the workings from any possible slides from the faces of the open pit.

FALLS FROM THE SIDES OF THE PIT

Soon water and atmospheric agencies began to act upon the gneissic footwall,

was resumed water had risen in the lower workings 200 feet.

Portions of the workings were still accessible through break-throughs at other points on the outcrop farther up on the strike. An examination under the collar of the shaft in the pit floor, showed that slabs from the hanging wall had covered the opening and had blocked any further slide of debris into the newer workings. The rock filling at the collar had been reinforced by ice which had formed from the percolating surface water.

METHOD OF RECLAIMING HOISTWAY

In the early spring Superintendent

SECTION, MINE 21, SHOWING RECLAIMED SKIPWAY

approximately 35 per cent. of the deposit left in pillars and floors, decided to shoot down the roof and overlying burden of sand and boulders. This was done and an open pit was formed, extending out from the hoistway in a broad fan shape, to points where the burden, because of the dip, became too deep to shoot down and rehandle economically. This involved some very cheap mining. The ore and rock was hoisted by the double-track incline, and two Lidgerwood cableways. The low cost

and upon the pillars which were supporting a very seamy hanging wall, overlaid with drift and boulders. In February, 1905, one of the pillars gave away and one side of the pit fell about 300 ft. vertically, wiping out a long stretch of the trestled hoistway and covering the ore floor to a depth of 100 ft. with loose material and rock. The discharge pipe from a triple-expansion Worthington pump operating at the main sump 500 ft. below the surface had been swept away and the workings began to fill with water. Before pumping

Clonan and I made preparations to reclaim the hoistway. The sides of the open pit were trimmed, the fallen stuff was partly leveled and sinking was begun to provide a shaft through the earth and rock. The 100 ft. of obstruction was of a very sandy nature piled up in the shape of a cone and during the period of sinking was in a constant state of movement.

Long shaft bearers, four in all, were laid and anchored in place by four 1 1/2-in. cables, hung at the corners and made fast to iron plugs back on the footwall.

*Mining engineer, Mineville, N. Y.

As sinking advanced on the 57-deg. angle, breast boards of varying lengths were used on the hanging-wall side. They were held in place by props resting against the material on the footwall side of the shaft. The wall plate was first introduced, the set interval lagged with 3-in. plank, and whenever possible the breast boards were removed. The footwall plate was next placed and finally the end pieces and divider. Very frequently the hanging plate would move back, and to place the last three sticks, it would be necessary to jack the wall plates. Shaft sets of square-set pattern were used and introduced at 2½-ft. intervals providing two compartments, 6x7 ft. inside measurement.

The weight of the earth on the hanging-wall side snapped many of the 1½-in. hanging irons first used; they were replaced by 1¼-in. iron, and great care was taken to have them cooled properly at the hook. Frequently, to hold back the drift, it was necessary to drive piling, but the presence of so many large boulders in the fallen material made this a slow method of procedure. Necessarily some block

hanging wall, boulders in the drift projecting from the sides, made the task of laying bearers at the bottom of the cave anything but desirable. The 50 ft. of timbering was still held fairly well in line by the cables.

BUILDING UP CRIBWORK

The next work was to trim the sides, to make it safe for men to work below. Again as little trimming as possible was done, for the material all fell to the bottom of the mine and had to be rehandled and hoisted to the surface. Men working with ropes around their waists, each attended by two men higher up who could pull them up in case of a fall from the sides, placed the first set of timbers on the collar.

Crib work of 10x12-in. yellow pine sticks was started up on the angle of 57 deg. to meet the 50 ft. of overhanging square sets. The sticks were thoroughly drift spiked and further strengthened by concrete walls built on three sides of the collar and to a height of 15 ft. from the ore floor. After the crib work had been

of the shaft had fallen through the collar, and crib work was begun, by working only in daylight a shift would advance 5 ft. in the 10 hours.

Gasolene Traction Drill

Drilling machines operated by gasolene power have been manufactured for a number of years, but only recently have these machines been so arranged that they could be moved from place to place by their own power. As these machines have to be moved over all sorts of roads it is essential that the power should be so mounted that the torsional strains shall not fall upon the moving parts. Certain features of automobile construction are being adopted, such as replacing the old friction drive by clutches controlling the forward and backward movements, the gears for each being always in mesh.

When set up ready to drill the road-driving clutch is thrown to neutral position, and the engine is connected to the drilling part proper with a belt and drilling commenced. A machine of this type

WEST SIDE OF PIT, AFTER THE FALL

MINE 21, OPEN PIT AND HOISTWAY

holing had to be done during the course of sinking, in which case crude logs were piled over the rock and also spiked to the timbers.

As the weight on the bearer cables increased, because of the timbering and also because the drift was in a state of movement, constantly pulling on the timbers, it was necessary to use more cables to keep the shaft sets near the true alignment. They were clamped at the hanging-wall corners around the wall plates and end pieces and drawn taut to other iron plugs on the footwall. As sinking progressed tracks were laid and by using lap-slides the skip cars were lowered to the bottom of the shaft, and the loose material was hoisted to the surface.

At a depth of 50 ft. the slabs, that blocked the collar 50 ft. below the last set of square-set timbering, gave away, and the bottom of the shaft fell out. It gave sufficient warning, so that the men in the shaft had time to climb some distance up the shaft timbers. The cave formed with funnel-shaped sides. Steeply sloping faces with large slabs from the

built to the proper height, and had been securely tied to the overhanging square sets, track stringers were laid and timber was lowered from the surface to rebuild the trestled track below the shaft collar.

LOG ABUTMENT TO PROTECT TIMBERED HOISTWAY

To protect the exposed timbered hoistway from any other falls, logs were lowered by the cableways and an abutment was built close to the timbered shaft, and on the west side of the open pit. Stretching across the bottom of the pit and for a height of almost 100 ft. these logs were placed log-cabin crib fashion and filled with the fallen earth and rock until a level floor of sufficient area was made to catch any later falls and to prevent the material from rolling over and upon the timbered skipway.

Sinking through the fallen ground was a very tedious piece of work, and consequently no remarkable headway could be made. Two 10-hour shifts advanced on an average of 2 ft. per day. After the material from the three sides and bottom

made by the Cyclone Drill Company, of Orrville, Ohio, has the front axle stationary, the wheels swinging in knuckles. Other features of this company's latest type machine are: A positive clutch for the spudder crank; a specially designed clutch to start or stop drilling without shutting off the engine; control of the engine speed by a worm gear that increases or decreases the tension of the governor spring; magneto and battery system of ignition, two spark plugs being used.

Rhodesian Mines

Gold production in Rhodesia in January is reported at 48,621 oz. fine, a decrease of 3016 oz. from December. By values the production for the month was \$970,316 in 1908, and \$966,041 in 1909; an increase of \$25,725 this year.

Other production reported for January was 20,172 oz. silver, 9 tons copper, 69 tons lead and 628 tons chrome ore. The coal output from the Wankie mines was 11,725 tons.

Behavior of Calcium Sulphate at Elevated Temperatures with Some Fluxes*

By H. O. HOFMAN and W. MOSTOWITSCH.

Hydrous calcium sulphate loses its combined water at about 900 deg. C. Anhydrous calcium sulphate heated at atmospheric pressure in pure dry air remains unchanged up to 1200 deg. C. At 1200 deg. it begins to be dissociated, with the separation of sulphur dioxide and oxygen, as at this temperature sulphur trioxide cannot exist as such. The rate and degree of dissociation vary with the time and the temperature. Calcium sulphate fuses at about 1360 deg. C. and is more or less decomposed; the resulting product is a mixture of calcium oxide and sulphate; the proportions of the components vary with the time and temperature of the preliminary heating. Silica decomposes calcium sulphate at an elevated temperature; the decomposition begins at 1000 deg. C. and is finished at 1250 deg.; the product contains only calcium oxide and silica; the reactions taking place may be expressed by

The examination of the product leads to the conclusion that the formation-temperature of calcium silicate lies below its melting-temperature.

Pure ferric oxide heated at atmospheric pressure in pure dry air is not dissociated at 1500 deg. C. Pure ferric oxide begins to decompose calcium sulphate at 1100 deg. C.; the decomposition is finished at 1250 deg.; ferric oxide requires on the whole higher temperatures to decompose calcium sulphate than does silica, but the decomposition proceeds at a more rapid rate. The process taking place may be expressed by the reaction

The calcium ferrite formed fuses at 1250 deg. C.; it has, however, the property of dissolving calcium sulphate and of decomposing it, which indicates the existence of ferrites other than given by the formula.

Pure lead oxide has no decomposing effect upon calcium sulphate.

THE CARMICHAEL-BRADFORD PROCESS

The gypsum added to the charge of raw sulphide lead-ore, characteristic for this mode of blast-roasting, is decomposed mainly by silica and ferric oxide; the sulphur dioxide resulting from the dissociation of sulphur trioxide set free enriches the gases.

Gypsum has no decomposing effect upon galena.

The lead sulphide of the charges is oxidized by the oxygen of the air blown into it; the sulphur trioxide dissociated into sulphur dioxide and oxygen at the temperature of decomposition of calcium sulphate cannot have any oxidizing effect in hot parts of the charge; in the upper cooler region of the converting pot there is a possibility of some sulphur trioxide being formed from sulphur dioxide and oxygen with the assistance of a catalyzing effect of the charge, but even here the newly formed sulphur trioxide can hardly have any oxidizing effect, as the equations

point toward the strongly exothermic direct oxidation by means of the excess of free oxygen present in the gases.

The decomposition of calcium sulphate with the simultaneous dissociation of sulphur trioxide,

represents two strongly endothermic reactions which must be favorable to the roasting of galena, as they counteract any tendency to local overheating and consequent fusion of the charge.

Further, the sulphur dioxide set free has a loosening effect upon the charge and thus acts favorably upon the process. From the thermal considerations it appears that in blast-roasting galena, calcium sulphate has a more favorable effect upon the result than calcium carbonate, which, according to

ORDINARY OXIDIZING-ROAST.

In the ordinary oxidizing-roasting of ores the temperature is usually not raised to above 900 deg. or 1000 deg. C. As gypsum is not decomposed at this temperature, its presence can but have the effect of increasing the percentage of sulphur in the roasted charge.

OXIDIZING-ROAST OF CALCAREOUS BLENDE

In the oxidizing-roasting of calcareous blende the calcium carbonate is converted into calcium sulphate; and the latter, not being decomposed at the temperature of from 1200 to 1250 deg. C. attained in the operation, might be expected to increase the sulphur content beyond the degree it actually does were it not for the presence of small amounts of silica in the gangue and of isomorphous iron sulphide in the blende converted into ferric oxide, both of which favor the decomposition of calcium sulphate, and are thereby helpful in the diminution of the sulphur content.

REDUCTION OF ROASTED CALCAREOUS BLENDE

On the other hand, the presence of large amounts of isomorphous iron sulphide in blende, as in many marmatites, has a harmful effect upon the reduction of roasted calcareous blende on account of the low temperature (1250 deg. C.) at which calcium ferrite fuses. The reduction of zinc oxide in practice is carried on at a temperature of 1300 deg. C.; the fused calcium ferrite, which is very fluid, will penetrate the charge, hinder reduction, and make rich residues; further, it will have a corrosive effect upon the retort material.

KNUDSEN PROCESS FOR PYRITIC SMELTING

In this process, it will be remembered, copper-bearing pyrite is smelted in a converter lined with dolomite. Practical experience has shown that the more basic—i.e., the richer in iron—the slag, the more quickly will the lining be slagged, while slags with a reasonably high percentage of silica do not corrode the lining as rapidly. The reason for this peculiar fact now finds its explanation in the formation of readily fusible calcium ferrate. The experiment given on page 68 has shown that magnesium ferrite does not form at a temperature as high as 1500 deg. C.; hence, the richer in magnesia the dolomite, the more resistant will it prove to slagging.

BASIC STEEL PROCESSES

The facts stated in the preceding paragraph regarding the ease with which calcium oxide is slagged by ferric oxide, and the difficulty of forming a magnesium ferrite, are important as regards the lining of basic-steel furnaces. Here it has also been found in practice that magnesia resists the corrosive effect of an iron slag much better than does lime.

ROLE OF FERRUGINOUS SLAGS IN NON-FERROUS SMELTING

The fluxing effect that basic slag rich in iron from copper- or nickel-refining furnaces has upon the blast-furnace-charge of acid ores, may be explained in part by the fusibility and fluidity of calcium ferrite. This oxide slag readily dissolves the less-fusible component parts of the charge, and helps to form at the desired temperature a slag of the required fluidity. The general principle of slag-formation by solution has been proved experimentally in a different way by Doelter,¹ who found, in observing slag-formation under the microscope, that the process was one of solution, in which the mineral having the lower melting point, after fusing, dissolved the one having the higher.

The Mining Industry in Queensland

The Chief Product of the Mines near Chillagoe Is a Copper-Lead-Silver Ore Averaging 8 Per Cent. Copper and 17 Per Cent. Lead

BY GERARD W. WILLIAMS*

The state of Queensland is one of the largest and least known of Australian colonies. It extends from the 29th to the 11th parallel and is bounded on the western side by the 138th meridian, the greater part of the state, therefore, lying within the tropic of Capricorn. The mines may be conveniently grouped as follows: The Northern fields comprising the Herberton tinfields, the copper country that extends for a radius of about a hundred miles around Chillagoe, and the goldfields of the extreme north; the Northwestern district comprising what is generally known as the Cloncurry field, the most important mineral here being copper; the Charters-Towers goldfields, the copper-gold district of which Mt. Morgan is the natural center; and the goldfields of Gympie. The various fields will be considered in this order.

The town of Chillagoe is situated 140 miles by rail from the port of Cairns. Along the coast and roughly parallel to it runs a range of the mountains varying in height from 2000 to 5000 ft. This belt of country, some 40 miles wide, is well timbered and of proved fertility but beyond the landward slopes of the range the country passes into rolling plains sparsely timbered with small eucalyptus and covered with indifferent grass. Geologically the country consists mostly of highly altered sedimentary rocks overlying granites. Newer intrusive rocks penetrate both the granites and the sedimentary series which are of Silurian age. Chillagoe itself is situated at the junction of the granite and the slates with the Permo-Carboniferous limestones which outcrop in bold craggy scarps sculptured into fantastic shapes.

THE COPPER MINES

The chief mines in this district are, the Ruddigore, Zillmantion and Mungana mines, in the neighborhood of the town, the O. K. about 60 miles northwesterly and the Einasleigh 120 miles south.

As these mines all present different geological features a brief description will be given of each.

The Ruddigore—This mine, the property of the Chillagoe Railways and Mines (Ltd.), is situated $2\frac{1}{2}$ miles by rail from the smelteries at Chillagoe. It is a low-grade copper mine. The orebody appears to consist of a stockwork of chalcopryite in a quartz porphyry; the surrounding rock is granite. As exposed by an open

cut, now 100 ft. in depth, the main shoot is 270 ft. long and 40 ft. wide with an average copper content of 2.75 per cent. At present this ore is hand picked up to 4 per cent. and shipped to the smelteries. The lode is nearly vertical, the hanging wall being clearly shown, but on the foot-wall side there is no defined wall and the values pass out into the granite country. From bore holes the lode has been shown to extend to 250 ft. in depth. The present mining manager for the Chillagoe mines, J. Rhodda, is engaged in sinking a shaft in the western country rock with a view to opening up the lode at 125, 225 and 325 ft. respectively. Till this is done it is naturally impossible to estimate the real value of the mine.

At the *Zillmantion*, which is situated about two miles from the smelteries, the orebody occurs as a contact lode between granite and limestone. The mine is interesting from a geological point of view in that it is intermediate in character between the pure chalcopryite granite orebody of the Ruddigore and the limestone deposits of copper-lead-silver-zinc ore at Mungana. The limestone is entirely converted into massive calcite and on the side of the orebody there is a layer of varying thickness of soft ferruginous clay. This clay renders mining extremely difficult for from its nature it makes a dangerous hanging wall and moreover it forms an impervious layer which dams back the water in the limestone. In places this clay becomes so thin that the water breaks through making the mine liable to flood. The whole limestone country is extremely wet. In developing the bottom level (350 ft.) the main level was carried in the solid granite and exploratory cross-cuts and false drives run out into the orebody. At the time of my visit the workings were flooded.

The Mungana mines—These mines, of which the Lady Jane and the Girofla are the most important, are the property of the Mungana Mines (Ltd.), a subsidiary company of the Chillagoe Rails and Mines (Ltd.). They lie in a wide ore belt that runs in an east-west direction through the massive Permo-Carboniferous encrinoidal limestone. The ore channel is proved for about three miles and numerous mines have been opened up on it. In one place a dike of granite crosses the orebody, converting the limestone on the contact to garnet rock. The limits of the ore are in some instances marked by the occurrence of crystalline schists. The orebodies consist of more or less

persistent caverns in the limestone which have been filled with mineral. The Lady Jane has been opened up to 426 ft. in the mine shaft, but the lowest level is 320 ft. Work on the 420 has been delayed owing to influx of water from a water course in the limestone, tapped in sinking.

The deposit takes the form of an almost vertical chasm in the limestone. In section it resembles an open fan and at the 320 level measures 260 ft. in greatest length by 60 ft. across the center. At the 210 level the deposit was 60 ft. longer and 10 ft. wider. The actual outline, however is irregular and varies considerably from one level to another. The nature of the ore too varies widely. On the same sill floor it is possible to pass from a straight copper ore assaying 30 per cent. metal in black sulphide through an intermediate sulphide ore containing black copper, galena, blende and anglesite, to a straight silver-lead ore. Lots of copper ore assaying 51 per cent. metal have been shipped. Black sulphides exist on the 320 level and in a winze sunk to 60 ft. below that level, thus indicating the essentially secondary nature of the deposit. The average shipping grade of copper-lead-silver ore is 6 per cent. copper, 21 per cent. lead, and 20 to 25 oz. of silver. The "copper" ore varies from 10 to 20 per cent. copper, 4 to 14 per cent. lead with from 4 to 50 oz. silver. As will be shown later this latter ore is treated only for its copper and silver.

The orebody does not stand well in mining and in consequence is timbered with square sets which are kept well mullocked up. The sets are constructed of round timber, the manner of cutting being shown in Fig. 1. An interesting phenomenon was observed in the stope over the 320 level. The stopes were up on the fifth set at the time when without warning the timbers began to take weight badly. Despite all strengthening it was found advisable to cease work and every effort was made to keep the drive open. Legs and caps were smashed in almost as soon as placed in position and at one time it appeared certain that the level must be lost. The No. 4 winze was sunk from the 210 level but when down to 54 ft. it was necessary to cease work owing to the intense heat. A blower was started but before work was resumed the heated air in the cavity X, shown in Fig. 2, was accidentally tapped through the winze No. 1 and escaped along the 210-ft. level driving out all men from the stopes above for several days.

*Consulting engineer, Stock Exchange Club, Melbourne.

On examination the following conclusion was arrived at: At some time the ground at X fell and in falling sealed the outlet of the fissure into the old No. 1 winze, which had previously acted as a vent; as oxidation proceeded the temperature and pressure of the inclosed air increased, and the broken ground acted as a great piston forcing down all the stope and drive sets with irresistible pressure. Some idea of the pressure may be gained from the fact that when the gas escaped from the No. 1 winze the floor of the new No. 4 winze fell into the cavity. The floor was only 14 in. in thickness but together with the broken ore lying on it, it had been held up against the winze by the caisson pressure inside.

At the Girofla the nature of the ore deposit is similar but there are two shoots at the surface which unite at the 410-ft. level. This mine is lower grade in depth than the Lady Jane, the ore on the 510 level averaging 2.2 per cent. copper, 20 per cent. lead and 6 to 12 oz. silver. From this mine large quantities of "flux sulphide" are mined and sent to the smelteries at Chillagoe, ten miles distant. This flux contains 1.5 per cent. copper, 12 per cent. lead and 6.5 oz. silver.

The carbonate levels of all the Mungana mines have yielded rich carbonate and oxide ores. The whole ore channel contains mineral deposits many of which have already been located and it is quite certain that exploratory work with the diamond drill will result in the opening up of other deposits. As to the permanence in depth of these cave deposits it is difficult to speak with certainty. The fissures or caves in which the minerals are deposited may extend downward for a considerable distance, but the presence of zinc renders it highly probable that in the primary zone the copper will be replaced by that metal. The Chillagoe company controls several other mines along the granite-limestone belt but none of these were working at the time of my visit. They are only profitable when copper stands at a high price.

THE CHILLAGOE LEAD AND COPPER SMELTERIES

The smelteries of the Chillagoe Rails and Mines Company, are situated at Chillagoe, 149 miles by rail from Cairns. As indicated in the foregoing description of the mines supplying ores to the smelteries highly complex ores have to be treated. For working purposes all ores received are classified as lead or copper ores according as they are treated in the lead or the copper-blast furnaces. The accompanying table shows the chemical composition of the ores at present being treated.

From time to time small parcels of high-grade copper ore are treated.

LEAD SMELTING

The ores treated in the lead smeltery

are the Lady Jane and Girofla sulphide and oxide ores (excepting the "flux sulphides") together with purchased ore from the Consols mine. The Lady Jane and Girofla ores are mixed in the proportion of 2 to 1 and crushed through a No. 5 Gates crusher, the product passes to a 36x30-in. Krupp roll and from this through another similar roll which delivers to the boot of an elevator. Half of this crushed ore is fed to two large Edwards roasters. The latter measure 89x16 ft. over all, the inside hearth measuring 83x14 ft. The hearth has a fall of 5 deg. (34 in. per ft.). There are two rows of 20 rabbles, the arms are 3 ft. 6 in. long with five "feet" to each arm. The rabbles are driven from two 3-in. shafts which run

20 mesh, 22, 10.9; through 20 mesh, 43, 6.3. The loss in weight is about 15 per cent.

The roast is wetted and after mixing with unroasted sulphide ore and some limestone is charged to the Huntington-Heberlein converters, of which there are 12 with kettles of 10-ton capacity each. Each pot or kettle averages 2.5 blows per day with air at 20 oz. The company is under agreement not to publish details of the working of this plant although it is not easy to see what danger to the patentees would lie in such publication. From the converters the blown charge is dumped direct onto the floor beneath. The kettles swing over and after the charge falls out they swing back again for the new charge which is run in from hoppers connected with the feed bins above.

FIG. 1. METHOD OF FRAMING ROUND TIMBERS

the length of the roaster. The roof of the roaster is 1 ft. 3/4 in. in the center arching down to 10 in. at the sides. The fireboxes are three in number, one at the end and two placed in the middle. Opposite to each rabble is a port, 9x10 in. The rabbles revolve at the rate of 1 r.p.m. (the last four travel somewhat faster) and discharge to a cross tunnel from which the roasted ore is removed by a push conveyer. Each roaster treats from 30 to 50 tons per day according to the degree of desulphurization required. The size and sulphur content of the partly roasted material is as follows, the second figure representing percentage of roasted ore, and the third figure, the per cent. of sulphur it contains: On 1/2 in., 15, 14.1; on 3/4 in., 12.3, 12; on 1 1/4 in., 7.5, 11.4; on

The fines, which average 70 per cent. and consist largely of unsintered sulphides, are mixed with sulphide ores and rebrown. At the time of my visit, work on these kettles had been greatly improved and, as a result of certain changes in the sulphur content of the charge, the fines had been materially reduced. The sintered charge has approximately the following composition: Silver 12 oz. per ton; copper, 4 per cent.; lead, 20; silica, 15; ferrous oxide, 27; lime (CaO), 1.2; zinc oxide, 15; sulphur, 4.5. From the floor beneath the Huntington-Heberlein plant the lumps of sinter are spalled up and railed to the smeltery floor.

The lead furnace has a rectangular water jacket, 40x160 in. at the tuyeres. From the top of the crucible to the feed

floor is 18 ft. 6 in. and the water jacket extends 8 ft. above the tuyeres. The jacket measures (inside) 5 ft. 8 in. by 14 ft. 10 in., is straight sided and built of 5/8-in. mild steel. There are nine tuyeres 4 in. in diameter to each side. The furnace charge is approximately:

H-H product.....	3200 lb.
Oxidized Girofla.....	600 "
Limestone.....	400 "
Lead slag.....	700 "
Copper slag.....	400 "
Dirty lead mattes.....	400 "
Lead dross.....	300 "

the percentage of lead less the percentage of copper, i.e., on an ore containing 26 per cent. lead and 4 per cent. copper the available lead would be 22 per cent. Recent experiments on blowing up the lead-copper matte direct, have been encouraging and this is looked upon as a possibility for the future.

COPPER SMELTING

The copper furnace measures 160x40 in. at the tuyeres, the water jacket ex-

tes (40 per cent. copper), 9; lead slags from lead furnace, 20; coke, 6 per cent. on the charge. From the smelteries the daily returns averaged 24 tons of matte containing 50 per cent. copper, 13 lead, 4 zinc, 16 sulphur and 16 iron (FeO). An average slag composition has been: silica (SiO₂), 37 per cent.; zinc (ZnO), 4; alumina (Al₂O₃), 9; iron (FeO), 26; lime (CaO), 19; lead, 3; copper, 0.4 and silver, 0.4 oz. per ton.

The converters are two in number but the present air supply is only sufficient to keep one blowing at a time. When freshly lined their capacity is about 1½ tons which is increased to 6 tons on the fifth "blow." Generally speaking each lining treats 11 tons of copper. The following notes, taken from the time slate illustrate the time required for converting: "Charged with 2 tons matte, blowing for 45 min., slagged off. Slag very viscous and has to be rabbled. Two tons of matte added, blowing for 20 min., and another half ton of slag skimmed off. After a further blow of 6 min. the converter slagged, and the metal, 2.1 tons of 99-per cent. blister, poured into molds." The blister assayed 100 oz. silver per ton. The gold content was inappreciable.

During blowing a large portion of the copper scorifies out into the slag, the action being very similar to that which takes place in an ordinary scorifier during the treatment of copper lead. The converter slags have the following composition: Silica, 22.5 per cent.; ferrous oxide, 34.5; zinc oxide, 13.6; alumina, 5; copper, 8.5; lead, 20; sulphur, trace.

The quartz used in the converter lining contains 92 per cent. silica. Eight parts of it are mixed with four of binder composed of red clay obtained locally and two of old liners. The lining is tamped with small pneumatic hammers. The dust is

FIG. 2. LADY JANE SHAFT AND PORTION OF WORKINGS SHOWING CAVE

It is made up in three heaps on the charging floor and a barrow load of coke equal to 13.5 per cent. added to each heap. Sixty-three charges go through per day (24 hours).

From the furnace the following products are obtained: (1) Lead bullion, 17 tons, 60 to 65 oz. silver per ton; (2) dross from the lead well, 8 tons; this is returned to the furnace; (3) matte, 20 to 25 tons; this matte averages: lead, 19 per cent.; copper, 23; sulphur, 20; ferrous oxide, 25; zinc oxide, 10 and silver 16 oz. It is tapped into cooling launders of cast iron from which it is broken out and sent to the copper furnace. (4) Slag. This averages: Silica, 25 per cent.; iron (FeO), 35; lime (CaO), 12; zinc (ZnO), 16.5; lead, 2.0; copper, 0.55; sulphur, 3.0; silver, 0.5 oz. per ton.

The lead bullion contains less than 0.25 per cent. copper. The recovery of lead varies from 85 to 89 per cent. of the "available" lead. The "available" lead is

tending up 7 ft. 9 in. The feed floor is 18 ft. above the level of the tym. There are sixteen 3-in. tuyeres arranged in two rows of eight each on the longer sides of the furnace. The tym measures 3 ft. 4 in. by 18 by 6 in., and is constructed of 5/16-in. copper.

The average day's run for the past three months has been: Ruddigore ore, 40 tons; Queenslander ore, 30; Lady Jane oxidized and carbonate, 15; lead matte from lead furnace, 20; Girofla flux sulphide, 15; limestone, 30; high-grade mat-

returned to the converters and the slags are stored and smelted periodically in the lead furnace with a charge of the following proportions: Converter slags, 88 tons per day; H-H product, 25; Girofla lead sulphide, 34; limestone, 20; lead dross, 6; coke, 14 per cent. on charge.

The production per day averages: (1) Lead bullion, 11 tons; (2) Copper matte; lead, 26; copper, 35 per cent. goes to the copper furnace; (3) Slag. The composition of the slag is: Silica, 25 per cent.; ferrous oxide, 37; lime (CaO),

13.5; zinc oxide, 12.5; lead, 3; copper, 0.5.

The running of this charge has a most beneficial effect upon the furnace, all zinc accretions upon the sides and bottom of the crucible are cut out and the whole furnace is washed out clean. Previously these converter slags were returned to the copper furnace but the process had to be discontinued as the slags ran up high in copper.

The lead furnace was blown in on the first of January, '08, and was running well at the end of September. The copper furnace started a few weeks later and has run continually except for a few days' stop caused by lead and "mush" getting into the well. This furnace is running below its true capacity for it is necessary to run it side by side with the lead furnace in order to treat the mattes. The supply of straight copper ore is somewhat limited at present. Another lead furnace has been blown in and work is proceeding on a new one for copper.

The difficulty of copper smelting on these complex ores lies in the fact that if the coke is allowed to increase lead bullion is reduced and this collecting in the well chokes up the furnace. Practically no lead is recovered from the copper furnace, the bulk being volatilized and the rest going into the slag. A small quantity goes into the matte and is mostly blown out in the converters. Smelting practice at this plant is still in a transitional stage but immense improvements have been effected in little over a year's time since the present manager, J. Horsburg, took charge. Hampered by expensive freight, costly and not too efficient labor, and a badly laid out plant, the work done by the smelters is more than creditable, and marks a new and entirely successful departure in Australian metallurgy. As time goes on and the operations of the Chillagoe Mines and Railway extend, these smelteries will become of immense importance not only to the company but to North Queensland as a whole. The entire district traversed by the Chillagoe railways is mineral bearing but in most cases the ores are extremely refractory.

THE O. K. COPPER MINES, LTD.

The leases owned by the O. K. company are situated 50 miles north of Mungana, the terminus of the Cairns-Chillagoe line. The intervening road is bad, even for North Queensland. For three months of the year, during the rains, the roads are almost useless and the dry creeks of summer, over which they run, become raging torrents. In the immediate vicinity of the mine the country rock consists of quartzites and shales, the latter of Silurian age, which have been subjected to considerable dynamic metamorphism and as a result it is difficult to state definitely what was the original nature of much of the rock. Petrological-

ly the "country" varies from a highly silicious, massive greenish rock containing a small amount of hornblende to a rock composed of granules of aluminum silicate with secondary quartz and calcite. The schistose nature of the rock in the immediate neighborhood of the lodes is essentially secondary, induced by pressure and side movements. In some respects the rock is not unlike the amphibolites which compose the lode-bearing rocks of Kalgoorlie (West Australia). No rocks which can be definitely referred to an igneous origin are found in the mine.

As is the case with most of the mines in the Chillagoe district the surface gozans are well leached and have proved of little value. Patches of carbonate and silicate of copper were found but they proved of comparatively small extent. The black sulphides come in at water level (55 ft.). The mine has been opened up to a depth of 200 ft., but there are indications that this level will be the last to yield payable ore. Therefore, this mine is of interest chiefly from a metallurgical point of view. With the addition of limestone the ore is practically self-smelting, basic and silicious ores occurring in approximately equal quantity. The composition of the ore is as follows, the first figure being for basic and the figures in parentheses for silicious ore: Silica (SiO_2), 5 to 20 per cent., (40 to 70 per cent.); iron (FeO), 20 to 50; (7 to 18); alumina (Al_2O_3), 0 to 2; (1); lime (CaO), 0 to 5; (1); copper, 2 to 8; (8 to 20). Only a very small proportion of the ore is oxidized; the rest is sulphide ore.

The furnace measures 72x36 in. at the tuyeres and is 11 ft. to the feed floor. It is fitted with a crucible for inside settlement and the slag and matte are tapped intermittently.

The average daily charge is made up of 35 tons basic ore, 35 silicious ore, 16 limestone and 14 of converted slags, flue dust, etc. The smelting is semipyrritic, 5 per cent. of coke being used. Flue dust is heaped up in the open and after weathering for a few months it is made up in a Huntington mill with 25 per cent. of kaolin ore. The mass is made into briquets by hand and after drying these are fed to the furnace. The slag runs about 40 per cent. of silica and 32 of ferrous oxide. The metal recovery is given as 90 per cent. Attached to the smelting furnace is a converter, which runs only two shifts a day, matte produced on night shift being returned to the furnace on day shift. The matte averages 48 per cent. copper.

All stores have to be brought 50 miles by road, to traction engines being used for this purpose. Mining costs \$4 per ton (2240 lb.), smelting \$6 and converting \$20 per ton of metal. With average ores, (8.5 per cent. copper),

blister of 99 per cent. is produced at the mine for \$205 per ton or delivered on the wharf at Cairns for \$230 per ton. Labor costs \$2.50@3 per shift of eight hours, and it is not too efficient.

To date the company has smelted 57,000 tons of ore for a return of 6360 tons of copper. The mine is now treating 8.5 per cent. of ore of which there is an estimated reserve of 30,000 tons. On another lease about a half mile away a rich shoot of black sulphide ore is being opened up.

The mine is only a small one but it has had a distinctly successful career having paid half a million dollars in dividends end erected a plant to the value of \$240,000 on an original capital of \$15,000. The working limit, with copper at \$350 per ton appears to be 6.5 per cent. ore so that there is but a poor outlook when the primary ore is reached. As in most mines in this district zinc occurs in the ore. Despite its small size the mine is of interest as an example of the small scale smelting which is carried on in mines remote from railways and ports.

Australasian Gold Returns

Gold output in Western Australia in February was 123,116 oz. fine. For the two months ended Feb. 28 it was 281,315 oz. in 1908, and 255,383 oz.—or \$5,278,707—in 1909; a decrease of 25,932 oz. this year.

In February New South Wales reports 28,222 oz. gold. For the two months ended Feb. 28 the total was 45,340 oz. in 1908, and 48,107 oz.—or \$94,373—in 1909; an increase of 2767 oz. this year.

New Zealand gold production in February was 33,443 oz. bullion in 1908, and 41,265 oz. in 1909; an increase of 7822 oz. The bullion reported this year was equal to \$704,461, or 38,581 oz. fine gold. Silver reported was 133,387 oz. in 1908, and 154,258 oz. in 1909; an increase of 20,871 oz. this year.

The growth in size of Lake ore carriers is illustrated by a statement showing the average cargo of vessels loaded at the Duluth, Missabe & Northern ore docks in Duluth for a series of years, in long tons:

1905.....	1,809	1906.....	6,973
1900.....	3,783	1907.....	7,516
1905.....	6,037	1908.....	8,325

The average cargo of 1908 was more than four and one-half times that of 1895—and was handled in a shorter time.

The Associated Oil Company is building a pipe line from the Sherman oilfield in California to the port of Redondo in Los Angeles county. Wharves are also being built at that place. The Mitsui company is preparing to put on a regular line of tank steamers to carry oil from Redondo to Japanese ports.

Mining Enterprises in France

SPECIAL CORRESPONDENCE

The mining interests owned by French capital are of two kinds. Sometimes these enterprises are due entirely to foreign initiative with controlling companies constituted under foreign laws; sometimes they are due only to French initiative and capital and are controlled by French companies. The former plan owes its popularity to the success of the Transvaal gold mines in 1895. The French public at that time became familiar with the shares of the English companies, some of which sold practically all their stock in France. Although some French financial groups tried to take a direct interest in these companies their efforts came too late and met with little success. Of the two banks organized at that time to deal in the gold mines, the Banque de l'Afrique du Sud and the Compagnie Française des Mines d'Or et de l'Afrique du Sud, only the latter continues business at this time. However, the principal Rand trusts have still their own offices in Paris.

Gold mines take a considerable place in French investments and have an important market on the Paris Bourse. French capital is, also largely interested in diamond mines. A large amount of De Beers stock—if not the largest part of it—is held by French capitalists. The Jagersfontein and the Premier Diamond have also a great number of French shareholders.

The mining shares in which French capitalists and speculators take the most interest are those of the Rio Tinto, whose prices are closely influenced by the American market, particularly by Wall Street. Besides the Rio Tinto we find very large investments in English companies, such as Cape Copper, Tharsis, Golden Horse-shoe, Lagunas and Lautaro nitrates; in Belgian companies such as Asturienne des Mines, Vieille Montagne and many collieries; in German companies such as Harpener, Zincs de Silésie; in Italian companies, such as Montecatini; in Russian companies, such as Naphthes de Bakou; in Austrian companies such as Alpines, and in Turkish companies such as Balia-Karaidin, Héraclea colliery, etc.

Aside from these financial interests in foreign companies there are a number of mining enterprises in which both management and capital are in French hands. The older of these companies were organized to work the French mines, especially the coal seams of the north and center of the country. As these mines are in rich industrial districts the promoters easily raised the money necessary for their large business. The French collieries, owing to their exceptionally good management, their sound financial organization and the regularity of their dividends, command prices for their stocks which yield an interest of 3 to 4 per cent. only.

France, having comparatively few mines, has not been contented with its own enterprises or with the financing of foreign companies. The law of 1893, which allowed mining companies, only "civil" up to that time, to adopt the commercial form of the "sociétés anonymes" (joint stock companies limited), gave a great impulse to the development of the mining enterprises in the colonies and abroad, but especially in Algeria and Tunis. The leaders in this line were some of the large financial groups, commonly called the "Haute Banque."

Among them the most progressive and successful one is the Banque Mirabaud. It started under the name of Société d'Etudes et d'Entreprises, an important bureau for the investigation of mining enterprises. Owing to the large means available and to care in the selection of mining experts, this bureau studies every proposal with a care that has almost excluded failure. The Banque Mirabaud controls entirely the Boleo in Mexico, the Phosphates de Gafsa in Tunis, the Penarroya in Spain, the Mokta-el-Hadid in Algeria, the Bor in Servia. It is largely interested in the Epinau colliery in France, in the Sels Gemmes et Houilles de la Russie Méridionale, in the Ouasta Mesloul (Algeria) in the Vieille-Montagne Zinc in Belgium. It holds also many interests jointly with Rothschild Brothers, not only in Boleo, Penarroya, in the doubtful enterprise of Ingauran in Mexico, but also in undertakings special to the latter group and above all in the Nickel Company, which, by its connections with the International Nickel Company, controls the European market for nickel. Its mines are in New Caledonia and its smelting works are in England, France and Germany.

Next to the Mirabaud and Rothschild groups, the importance of which extends far beyond their mining enterprises, there exist a number of secondary groups of more recent date. We may instance:

1. The Bonnardel group, with interests in the Platinum Syndicate and the new gold-mining companies of French Guiana.
2. The Max Lyon-Achille Adam group with Catemou in Chile, Tuco-Cheira in Peru, and above all in Algeria and Tunis with Djebel-Ressas and Fedj-Assène.
3. The Vassal group with the Sosnowice colliery in Russia.
4. The Leonino group, chiefly interested in the French gold mines.
5. The Urruty group—representative of the Metallgesellschaft—dealing chiefly with Algerian and Tunisian mines such as Guelma, Safsaf and Kanguet.
6. The Bondeli group, with mines in the same countries, such as Djendil, and Djebel-Ressas; also connected with the Max Lyon group, and having unofficial help from the Credit Lyonnais.
7. The Rodocanachi group with Bou-Thaleb and French Laurium.

There are also different groups at Lyons and Paris with interests in Russian collieries and in gold mines in Madagascar, French Guiana and French West Africa.

The great banking institutions have often been criticized for their systematic indifference to industrial enterprises. This is not quite justified as some of them are directly or indirectly interested in mining companies. Among them may be instanced the Société Générale in Ekaterinowka and Routhenko, Russia; the Compagnie Française des Mines d'Or et de l'Afrique du Sud; the Omnium d'Algerie Tunisie; the Credit Industriel et Commercial in the Bethune colliery in France, the Czeladz Platinum in Russia, and the Omnium d'Algerie-Tunis. The Comptoir National d'Escompte de Paris is interested in the Compagnie Française des Mines du Laurium, in Greece.

To complete this general note we must mention the considerable interests of the great iron works in the iron mines of Lorraine and Algeria.

Many important foreign firms, such as the Metallgesellschaft of Frankfurt and Müller, of Rotterdam, have representatives in Paris and take a part in the mining business of France. We may add that the principal foreign manufacturers of mining machinery such as Fraser & Chalmers, Ltd., Krupp, Humboldt, Gröppel, Bleichert and Koppel, have in Paris branches or agencies carrying on a large business with the mining companies.

The number and importance of French mining enterprises has increased considerably in the last few years, principally during 1905-1906, when the majority of the new undertakings were connected with mines. It has been frequently noticed that at the time of financial crises, French investors feel inclined to buy only bonds and mortgage securities, while during prosperous times capital is willingly applied to industrial undertakings and principally to mining.

At present signs of a revival are obvious. A number of new mining ventures are being planned, some of which are ready and only awaiting a favorable time for soliciting capital and adding a few names to the already long list of French mining enterprises.

The French bronze coins of 5 and 10 centimes are to be withdrawn from circulation (*Min. Journ.*, Feb. 6, 1909) and replaced by aluminum coins 3 and 7 grammes lighter in weight. The standard of the aluminum must not be less than 990/1000, which is the same as that of commercially pure aluminum. There are to be coined 348,750,000 ten-centime pieces and 562,500,000 five-centime. It has been pointed out that pure aluminum is too soft for this use, and experiments are being made to solve this problem.

The Mammoth-Grand Central Case

SPECIAL CORRESPONDENCE

The Federal Supreme Court has just handed down a decision in the case of the Mammoth Mining Company against the Grand Central Mining Company, the latter being a Utah and Colorado corporation. This was a suit begun by the Grand Central Mining Company to recover for the removal of ores from beneath the surface of its Silveropolis mining claim and for an injunction. The defendant, the Mammoth Mining Company, filed a counterclaim, setting up that it was the owner of certain mining claims which were said to be senior to all other claims concerned, and that the vein or lode from which the ore in question was taken has a part of its apex within the Mammoth Mining Company's original holding which, if true, would entitle the Mammoth company to the ore. The case was originally decided by the Supreme Court of Utah in an elaborate opinion, and it was then appealed to the United States Supreme Court on the ground that the decision rested on a definition of a lode or vein which the plaintiff in error contests, and which, therefore, turned on the construction of Revised Statutes, Sec. 2322. The Federal Supreme Court dismisses the writ of error largely upon the same ground that was taken by the Utah court. It lays great stress on the fact that the Mammoth company could not locate the hanging or footwall of the supposed vein, the presumption being that the ore belongs to the owner of the claim under which it is found. The mines in question are found in a lime belt, which covers about two square miles, and is the great producing area of the Tintic district. In some places the limestone beds are upturned, large areas tilted upon edge, the beds dipping vertically, while in other places they dip at lower angles and in special areas the dips are quite uniform; and again it seems, though not frequently, anticlinals exist. This limestone is surrounded on all sides except the north by igneous rocks. The sedimentary rocks are broken up and fractured—evidently the result of igneous intrusion. The limestone carries some iron in the different forms of iron oxide, also some manganese, and in places the limestone is crushed, crumbled and brecciated. The view is taken that under such circumstances a vein cannot be said to exist merely because the rock is crushed, shattered, or even fissured, and that what will constitute one must depend somewhat on the nature of the country in which it is alleged to be found. It is recognized that a true vein may be barren in places, but the decision of the Utah Supreme Court is accepted to the effect that to allow the Mammoth company's claim would amount practically to declaring the whole limestone area to be one vein, thousands of

feet wide. The Federal Supreme Court, however, while noting that the Supreme Court of Utah expressed the opinion that there is a difference between a lode sufficient to validate a location and an apex giving extralateral rights, remarks that this question is not necessary to a decision in this case, and that it will not, therefore, express any opinion on that matter at the present time.

The National Conservation Commission

SPECIAL CORRESPONDENCE

It has been unofficially made known that at the recent meeting of the Joint Conservation Committee, which met last week in Washington in executive session, it was determined that the work of the committee could no longer go on under Federal control and at Federal expense. This committee is the organization resulting from the National Conservation Conference which met in Washington early last winter, and, on disbanding, left behind it resolutions favoring the establishment of a national committee under the control of the Federal Government to coordinate the efforts of the States and of private organizations in the interest of conservation. The committee was to consist of six members of State conservation commissions and three members of the national conservation commission, all of whom were to be designated by Chief Forester Pinchot, who was to act as chairman. Upon reaching Washington it was found by the members that the action of Congress in attaching to the sundry civil appropriation bill a rider prohibiting the use of funds of the National Government for the support or expenses of any board or commission not authorized by legislative enactment would prevent the expenditure of Federal moneys in connection with conservation. The work of the committee will, however, by no means be abandoned. There are at present about 37 State conservation commissions and about 50 committees of national organizations of private individuals, all needing leadership and aid. The committee intends to supply these, and it will rely for funds upon private contributions. Of the latter an adequate supply is understood to be in sight. At the recent meeting in Washington, a good deal of time was spent in considering this situation, but full attention was also paid to the large number of letters and suggestions received from the various State commissions and private organizations. A digest of these suggestions is being prepared and will probably be made known within a short time. No definite time has been fixed for the next meeting of the committee, but it is expected to occur soon.

The Bureau of Mines Bill

SPECIAL CORRESPONDENCE

After various efforts to get the bill to establish a bureau of mines before the Senate for discussion and a vote, it was finally brought up during the evening session of March 3, but a vote was prevented by a filibuster. Had a division actually occurred, probably the bill would have passed. The defeat of the measure was due to the success of opponents in preventing it from being taken up until the session was close to its end, when the time of the Senate could easily be occupied by anyone who wished to prevent the adoption of a given proposal. With greater energy and adroitness it would have been entirely practicable to have brought the subject to an issue much earlier. The final test, however, showed the location of the opposition as well as its character much more accurately than at any time heretofore. Those who were chiefly instrumental against the bill were Senators Clay, of Georgia; Teller, of Colorado; Clapp, of Minnesota, and Stone, of Missouri. With the concealed assent and support of a number of other senators this group was entirely adequate to accomplish the object in mind—the postponement of the bill to which they were antagonistic.

OBJECTIONS TO THE BILL

The principal objection to the bill, as developed in the course of discussion, was the unwillingness of the Senate to increase the number of Government bureaus and departments now in existence. Thus Senator Clapp voiced the apparently prevailing opinion, saying: "The bill is simply designed to establish another bureau for the government of this country and the government of Congress. Sooner or later Congress has got to take the stand that Congress will determine first and for all time in a session what the appropriations will be."

This view seemed to be supported by others on the ground that the marked success the Geological Survey has already had in enlarging its appropriations would be repeated in the case of a bureau of mines, were one to be created. The fear of interference with the "reserved powers" of the States also figured to some extent, Senator Carter stating that: "We have in the respective States certain laws relating to the inspection of mines. * * * The Federal inspectors of mines might prescribe one rule with reference to the safety of mines whereas the State law might prescribe another rule. How could the mining operator in the State of Montana, working a gold mine or a copper mine, determine when he was within his rights and complying with the law, should the law of the United States provide that an inspector appointed by the President, or by the bureau of mines, should insist

upon a rule fixed by Congress, whereas the State law provided for another rule of action entirely? I think the senator in charge of this bill should state clearly and distinctly the right, as he understands it, under our system of government for a Federal officer to enter a State to prescribe the method of conducting a mining operation in that State."

Senator Carter further remarked that the Federal Government had properly regulated and provided for inspection of coal mines in the Territories, and he thought that it might now with propriety make a similar provision for the inspection of quartz mines in the Territories. It could go no further.

Senator Teller plainly placed his opposition on the ground that the bureau would be of no real service. In the course of a long speech he said: "My objection to the bill is twofold: First, that it will be a great waste of money, an expenditure without return, and that it will be an absolute interference with the mining operations of this country, particularly with the mining of precious metals. * * * There is not in any section of the world men engaged in that industry who know any more about it than the miners of Colorado, Montana, Idaho, California and Utah. We do not need the fostering hand of the Government. We do not need any man to come from Washington out there to tell us how to develop our mines or, in the words of the bill, how to promote and develop the mining industries of the United States to make diligent investigations of the methods of mining, the safety of miners. Everybody who has lived in a mining country knows how to do that. If they did not know, my experience is that they could not get any relief from a bureau established here in Washington."

Although Senator Newlands interposed to assure Mr. Teller that numerous conventions of mining experts in the West had united in asking for the bill, the speaker only answered by the general charge that such conventions were not representative, and hence could not be trusted to interpret popular feeling.

It is intended to introduce the bill again at the next session of Congress and to make an effort to secure its early passage.

Tariff Revision Notes

SPECIAL CORRESPONDENCE

The manufacturers of ferro-alloys have suggested to the Ways and Means Committee a new draft of language which they wish to have inserted in the paragraph of the new tariff corresponding to paragraph 183 of the present tariff. The proposed language is also approved by General Appraiser Fischer, who has had particularly under his supervision the various questions concerning the importation of ferro-

alloys. The proposed wording is as follows:

Paragraph 122. Strike out the word "ferrosilicon."

Paragraph 183. Insert the following words: "Chromium or chromium metal, tungsten, molybdenum, titanium, silicon, tantalum, ferrosilicon, ferrochrome or ferrochromium, ferrotungsten, ferromolybdenum, ferrotitanium, ferrovanadium, ferrotantalum, ferrophosphorus, ferroboreon, and all other metals and alloys, all the foregoing crude or refined but unwrought, whether capable of being wrought or not, and whether produced in electric furnace or blast furnace or by chemical or other process, not otherwise specially provided for in this act,—ad valorem."

TOOL STEEL

In a detailed brief submitted to the Ways and Means Committee the Columbia Tool Steel Company, of Chicago Heights, Ill., demands that a duty be placed on all foreign tool steels sufficiently high to protect the American maker against unfair competition by inferior grades, and also to protect the buyer and direct his attention to the superior quality of American-made tool steels. The demand is made apropos of a brief filed some time ago by several firms in Boston in which reference is made to the fact that European steels can be duplicated or excelled in this country by half a dozen tool-steel makers selling at a lower price. The Columbia Tool Steel Company then says: "If it were possible for all tool steel entering the United States to be classified according to its quality as shown by analysis, there would be no need of a protective tariff. The traditions built up prior to the manufacture of tool steel in America still have such a strong hold among certain classes, that when a standard European make of steel fails to give results the workman invariably will take the blame on himself for not giving it the proper handling, whereas if a failure occurs with American steel it is always the steel that is at fault. . . . This would be manifestly impossible, in addition to which the tool-steel consumer has no facilities for making chemical analysis."

BISMUTH ORES

A new tariff treatment of bismuth has been proposed to the Ways and Means Committee by the Monsanto Chemical Company, of St. Louis, Mo., which recommends that in connection with the duties on lead there shall be a change in the wording intended to meet the conditions of production of bismuth. The change proposed is as follows: "Lead bullion or base bullion containing 95 per centum lead or less—per pound on the lead contained therein. *Provided*, that in levying and collecting the duty on lead, duty shall also be levied and collected on any other dutiable material contained therein. *Provided*, that in no bullion containing bismuth shall such

bismuth be dutiable unless such bismuth is equal to or exceeds 75 per centum of said bullion."

It is argued that should the revised wording be employed it "will have the effect of building up a new industry in this country at the expense of a foreign monopoly, which at the present time exists."

The Tennessee Merger

SPECIAL CORRESPONDENCE

The confidential report of the majority of the Senate Judiciary Committee relative to the question whether President Roosevelt was authorized to permit the merger between the United States Steel Corporation and the Tennessee Coal, Iron and Railroad Company has now become public. It shows that a majority of the committee who censured the President, based a considerable part of their argument upon the alleged fact that he allowed a monopoly to come into existence, and that this monopoly consisted in large part of a control of iron-ore deposits. The majority report says: "Another important factor entering into the potential capacity of the Tennessee company is the proximity of the iron ore, coal and limestone holdings to each other and to the plants, and the consequent saving of transportation charges." Referring then to the report of the National Conservation Commission, the majority report quotes the following: "The known supply of high-grade iron ores in the United States approximates 3,840,000,000 tons, which at the present increasing rate of consumption cannot be expected to last beyond the middle of the present century." The majority continue as follows: "If, then, the United States Steel Corporation now owns and controls 2,400,000,000 tons of high-grade iron ore, as has been estimated, it has 62½ per cent. of the total supply of the country. If this corporation acquired 700,000,000 tons of iron ore with the Tennessee company, it added to its then estimated holdings of 44 per cent. of the iron-ore supply 18½ per cent., giving it as stated control of 62½ per cent. of the iron-ore supply of the United States. The purchase of this 700,000,000 tons of iron ore from the Tennessee company, increasing the Steel Corporation's holdings of ore more than 40 per cent., created that future monopoly in ore and commanding position in trade to which Judge Gary testified before the Ways and Means Committee. The Steel Corporation, it is admitted, now practically controls the ultimate iron-ore supply of the United States."

Pulp for concentration on blanket and canvas tables is diluted to 7 water to 1 ore at the Giant mine, Rhodesia (*Journal*, Chem., Met. and Min. Soc. of South Africa, Nov., 1908), in order to obtain maximum efficiency.

Lake Superior Iron Ore

Shipments of iron ore by rail from the Lake Superior region in 1908 have now been reported in full. They were 587,893 tons—against 975,959 in 1907—and make the total for the year 26,044,987 tons, or 38.5 per cent. less than in 1907. The all-rail shipments are chiefly from the Mesabi range to the Zenith furnace at Duluth, from the Newport and Hemlock mines to Mayville, from the Illinois and Mayville mines in Wisconsin to Chicago and Mayville and from some of the Cleveland Cliffs company's Marquette range mines to the charcoal furnaces of Michigan.

The shipments, as apportioned by ranges, were as follows, in long tons:

Range:	1907		1908	
	Tons.	Perct.	Tons.	Perct.
Marquette.....	4,388,073	10.4	2,414,632	9.3
Menominee.....	4,964,728	11.8	2,679,156	10.3
Gogebic.....	3,637,102	8.6	2,699,856	10.4
Vermillion.....	1,685,267	4.0	841,544	3.2
Mesabi.....	27,495,708	65.0	17,257,350	66.3
Baraboo.....	95,790	0.2	122,449	0.5
Total.....	42,286,668	100.0	26,014,987	100.0

The shipments do not include those from the Michipicoten range in Canada, which were 148,000 tons in 1908, all from the Helen mine.

On the old ranges the Gogebic shows a smaller proportional decrease than the others. The Vermillion range had the largest proportional decrease, which was chiefly due to the abandonment of the Chandler mine, which was the chief producer up to two years ago.

The larger productions on the Marquette range were 438,379 tons from the Cleveland Cliffs and 278,366 from the Hartford; on the Menominee, 391,620 tons from the Chapin, and 365,361 from the Pewabic. On the Gogebic the leading producers were the Norrie, with 773,243 and the Newport with 579,390 tons. The Vermillion had only one great shipper in 1908, the Pioneer, with 477,506 tons. The Mesabi leaders were the Hull-Rust, 2,026,683; the Burt, 1,460,998; the Fayal, 1,430,879; the Adams, 765,592; the Virginia, 661,329; and the Mahoning, 611,592 tons.

The Oliver Iron Mining Company—the mining department of the Steel Corporation—in 1908 shipped a total of 14,123,957 tons, or 54.3 per cent. of the total. Only a small part of this came from the Hill lands, though a good deal of development and exploration work was done there.

Notwithstanding the dull year, shipments were made from six new mines—one on the Marquette, two on the Menominee, and those on the Mesabi range. Shipments are also reported from four old mines, which had been closed for several years previously—two on the Menominee and one each on the Marquette and the Mesabi.

Records of the shipments of Lake Superior ore have been kept from the first, and it is possible to give a statement of

the total production up to the end of 1908. The figures are as follows:

Range:	Year Opened.	Total Ore.	Per Ct.
Marquette.....	1859	87,605,566	21.6
Menominee.....	1877	66,320,369	16.3
Gogebic.....	1884	56,807,198	14.0
Vermillion.....	1884	27,636,970	6.8
Mesabi.....	1892	167,492,908	41.2
Baraboo.....	1892	737,868	0.2
Total.....		406,705,819	100.0

The Baraboo range in Wisconsin is included, although it does not adjoin any of the other ranges, because there is some evidence of its geological connection with the Gogebic deposits. The date for the first shipments from this range has been set back to 1892, owing to the inclusion this year of the Mayville mine, which had not previously been reported.

In all there were 162 shipping mines in 1908, of which 25 were on the Marquette range; 34 on the Menominee; 18 on the Gogebic; 6 on the Vermillion; 77 on the Mesabi; and 2 on the Baraboo range. In 1907 shipments were made from 179 mines.

Hydraulic Mining in California

SPECIAL CORRESPONDENCE

The great quantity of water which has fallen this year in California has favored the hydraulic miners. This particular branch of the gold-mining industry is now most active in the counties of Siskiyou and Trinity, on the northwestern coast of the State. In those sections, as well as in the counties of Humboldt and Del Norte, there is no restriction on hydraulic mining as there are no navigable rivers and most of the larger tributary streams empty into the Klamath river which carries the drainage into the Pacific ocean. These northern counties, however, are not as well equipped with general ditch systems as the more central mining counties of the State. In Nevada, Placer and other central hydraulic mining sections, extensive ditch and reservoir systems were devised and built before there were any restrictions laid upon hydraulic mining, and these systems still exist. In Siskiyou and Trinity, however, each mine has to provide its own water supply and there are few public ditches from which water may be purchased. In these counties there are large bodies of auriferous gravel which have never been mined for this reason. The ground is of little value without a water supply and considerable capital is usually necessary to furnish this. There are few very large hydraulic enterprises in those regions though there are numbers of small ones, each with its individual water supply. However, the largest hydraulic mine in the world—the La Grange near Weaver-ville—is operating in Trinity county.

Hydraulic mining in California is now receiving the attention of both the national Congress and the State Legislature. In Congress Mr. Englebright has introduced a bill, an abstract of which has been given in the JOURNAL. Its real

purpose is to permit miners to let hydraulic debris pass into mountain gulches or streams, provided they remove an equal amount from any place designated by the engineers of the California Debris Commission and pay for said removal. That is, if a miner some hundreds of miles from a navigable stream, lets any tailings get into a stream, he is privileged, if he pays for it, to remove an equal amount from some part of the stream or tributary where it is navigable. In this way he might continue to mine and yet not add any volume to the debris already in the river. The Anti-Debris Association is opposed to this and has resolved to send telegrams to Washington urging the defeat of the bill. In the State Legislature, Caminetti has a bill which creates an advisory board to the State Department of Engineering, composed of men who have interest and experience in gravel-mining matters. The River Commission people already have such an advisory board. The board is to be given powers only to advise with, and make recommendations to, the State engineer and the California Debris Commission, on matters pertaining to hydraulic mining. The California Miners' Association has sent a special committee to Sacramento to urge the passage of the bill, and the Anti Debris Association has sent a similar committee to try and defeat the measure.

Canadian Iron Production

The total production of pig iron in Canada has been heretofore reported. The detailed figures, as collected by the American Iron and Steel Association are as follows, in long tons:

	1907.	1908.	Changes.
Foundry and forge.....	84,979	114,951	I. 29,972
Bessemer iron.....	164,910	112,811	D. 42,099
Basic iron.....	341,257	335,410	D. 5,847
Total.....	681,146	663,172	D. 17,974

The total decrease was 3.1 per cent. Basic iron was made in 1908 by four companies owning nine furnaces and bessemer pig by two companies owning three furnaces. The basic and bessemer iron was all made with coke. Canada has not made spiegeleisen or ferromanganese since 1899.

On Dec. 31, 1908, Canada had 16 completed furnaces, of which 10 were in blast and six were idle. One of the idle furnaces was being rebuilt. Of the total 13 usually use coke for fuel and three use charcoal. In addition one coke furnace was projected and two coke furnaces upon which work was suspended some time ago were partly erected.

During the first half of 1908 the total number of furnaces in Canada actually in blast for the whole or a part of the period was 14, of which 11 used coke and three charcoal. During the last half of the year the total number of active furnaces was 11, of which nine used coke and two charcoal.

Comparative Tests of Run-of-Mine and Briquetted Coal

After a series of tests in burning run-of-mine and briquetted coal on a locomotive and on a torpedo boat, Mr. Goss, the engineer who conducted the tests, gives the results as follows:

(1) The briquets made on the Government's machines have well withstood exposure to the weather and have suffered but little deterioration from handling. (2) In all classes of service involved by the experiments, the use of briquets in the place of natural coal appears to have increased the evaporative efficiency of the boilers tested. (3) The smoke produced has in no test been more dense with the briquets than with coal; on the contrary, in most tests the smoke density is said to have been less when briquets were used. (4) The use of briquets increases the facility with which an even fire over the whole area of the grate may be maintained. (5) In locomotive service the substitution of briquets for coal has resulted in a marked increase in efficiency, in an increase of boiler capacity, and in a decrease in the production of smoke. It has been especially noted that careful firing of briquets at terminals is effective in diminishing the amount of smoke produced. (6) In torpedo-boat service the substitution of briquets for coal improves the evaporative efficiency of the boiler. It does not appear to have affected favorably or otherwise the amount of smoke produced. The briquets used in this series of tests were of a form requiring considerable bunker capacity for their storage, but as the form of the briquet is a detail entirely within control, this objection need not apply to the use of the briquets in actual service.

LOCOMOTIVE TESTS

Many low-volatile coals, such as those mined in the vicinity of Johnstown, Cambria county, Penn., are semi-smokeless and therefore very desirable for use in locomotives at or near terminals; nevertheless, on account of their low evaporative efficiency, they have not been found altogether satisfactory when used as locomotive fuel. Their tendency to disintegrate rapidly on the grate during combustion causes large quantities of cinders and sparks of high calorific value to be discharged. These cinders accumulate in the smoke box of the locomotive, obstruct the draft on the fires, and reduce the capacity of the boiler. The investigation here reported, therefore, was undertaken to determine in what measure, if any, the process of briquetting will serve as a remedy for these defects and to discover the effect of the process on efficiency and capacity.

The coal selected for the tests was taken from a mine working the Lower Kittan-

ning coal bed near Lloydell, Cambria county, Penn., on the South Fork branch of the Pennsylvania railroad. Its characteristics as a locomotive fuel were therefore well known. The Lloydell coal is a friable, low-volatile bituminous coal, and the carloads selected for the tests consisted of run-of-mine. The coal was exposed to the weather for 30 days on the way to the St. Louis testing plant, before being briquetted. It showed but little change due to this exposure except a decided increase in moisture, which, however, was eliminated in the briquetting process.

The binding material in all the briquets was water-gas pitch. This material was furnished at the briquetting plant of the United States Geological Survey, in St. Louis, at \$9 per ton, or 0.45c. per pound. The least amount of binding material that would make perfect briquets was found to be 5 per cent. of the weight of the coal. The cost of the binder in one ton of the 5-per cent. briquets was therefore 45 cents.

The cost of briquetting, including all charges, is estimated to be about \$1 per ton of briquets; that is, the briquetting added approximately \$1 per ton to the cost of the coal. The briquets were made, however, in an experimental plant, and the price is for this reason probably not so low as if they had been made on a much larger scale. After the coal was made up into briquets it was returned to the locomotive testing plant at Altoona, Penn., for the tests.

To observe the effect on briquets of exposure to the weather, a number of the round and square briquets were placed on the roof of the testing plant. After four months of exposure for the round and three months for the square briquets, no change whatever from their original condition was noticed. They appeared to be entirely impervious to moisture and were still firm and hard.

The briquets were little affected by handling. They were loaded at St. Louis in open gondola cars and shipped to Altoona, where they were unloaded by hand and stacked. They were handled a third time in taking them to the firing platform of the test locomotive. After these three handlings they were still in good condition, very few were broken, and the amount of dust and small particles was practically negligible.

The results of the tests justify the following conclusions: (a) The evaporation per pound of fuel is greater for the briquetted Lloydell coal than for the same coal in its natural state. This advantage is maintained at all rates of evaporation.

(b) The capacity of the boiler is considerably increased by the use of briquetted coal. (c) Briquetting appears to have little effect in reducing the quantity of cinders and sparks; the calorific value of these, however, is not as high in the briquetted as in the natural fuel. (d) The density of the smoke with the briquet-

ted coal is much less than with the natural coal. (e) The percentage of binder in the briquet has little influence on smoke density. (f) The percentage of binder in the briquet has little influence on smoke density. (f) The percentage of binder for the range tested appears to have little or no influence on the evaporative efficiency. (g) The expense of briquetting under the conditions of the experiments adds about \$1 per ton to the price of the fuel, an amount which does not seem to be warranted by the resulting increase in evaporative efficiency. (h) With careful firing, the briquets can be used at terminals with a considerable decrease in smoke. (i) The briquets appear to withstand exposure to the weather, and suffer little deterioration from handling.

Briquets made from Arkansas semi-anthracite, two qualities of Indian Territory slack, Indian Territory screenings, Missouri slack, Indiana Brazil block slack, coke breeze, and a mixture of coke breeze and washed Illinois coal were tested, and comparisons were drawn either with the same coal that was used in the briquet or with coal similar to it. In nearly every test the results reported show that the coal when burned in the form of briquets gives a higher evaporative efficiency than when burned in the natural state. For example, Indian Territory screenings give a boiler efficiency of 50 per cent., whereas briquets made from the same coal give an efficiency of 65 to 67 per cent. Decrease in smoke density, the elimination of objectionable clinkers, and an apparent decrease in the quantity of cinders and sparks are named as the chief reasons for this increased efficiency.

Australian Iron Bounties

The Australian Parliament at its latest session passed a bill for "the encouragement of manufactures," and regulations prepared under this act have been issued by the government. A bounty of 12s.—\$2.88—per ton will be paid on pig iron made from Australian ore, the quantity to be 1000 tons or over; and the same amount on bar iron puddled from Australian pig, at least 250 tons in quantity; and on steel made from Australian iron, not less than 100 tons to be considered. Bounties of 10 per cent. on value—which apparently means current price—are to be paid for iron or steel sheets or plates, minimum 100 tons; steel or iron wire or wire netting, minimum 50 tons; iron or steel pipes and tubes, minimum 50 tons. All are to be made from Australian iron. The year for bounties is to begin May 1, and the total amount to be paid is limited to £180,000 in five years.

During the first 11 months of 1908, an average of 8981 stamps were dropping on the Rand, and the average duty per 24 hours per stamp was 6.21 tons.

Colliery Notes

To get maximum efficiency from your ventilation, split your air as near the fan as possible.

Pumps should be set as close to the sump or water supply as practicable, so that there is no danger of drowning the pump in case of an accident.

One mine foreman states that a good mixture of mortar for stoppings is made by taking one part of cement to about seven parts of fine coal dust.

When searching for an unexploded charge in material blown down, great care should be taken that the detonator be not struck with a pick or other tool.

When any quantity of coal at the face is supposed to contain a portion of an unexploded charge, and the explosive is not recoverable, the coal should be securely packed in the goaf.

The principal difficulty in the utilization of peat under boilers appears to be the frequency with which it is necessary to fire. This disadvantage is caused by the lightness of the material and also on account of its rapid combustion.

The mine foreman who persists in his assertion that it is better to always curse his men in order that the maximum effort may be obtained, is making the mistake of his life. Those miners who only answer to rough handling are exceptions, and any organization will prosper better without them.

If a general examination were held and all coal-mine managers and superintendents were asked to tell what they know concerning the laws that regulate coal mining in their respective States, it would be surprising what little time would be required by some of these officials in telling all they know.

The fireboss who makes his rounds at 3 a.m., aided only by the light of a dim safety lamp, has no easy task; for this reason, he should insist on the miners keeping their places safe and clear. When miners do not keep their places in a condition that permits easy travel, the fireboss should stop them from working until they clean up.

Any loose rock or dangerous top in a working place should be taken down immediately after it is discovered. Nothing is more important than that the miner should make his place safe, and when orders are given to pull down dangerous roof, or to put props under it, the miner who disobeys or delays should be punished.

It is stated on good authority that an economical plan ought to make peat fuel at 60c. per ton. This result is accomplished by first draining the water from the bog, and then using a dredge which can take up an entire section of peat, 12 to 14 ft. in depth, at one time. Recent tests

have proved that a good quality of peat has a calorific value of 10,082 B.t.u. per pound.

As long as the cost of coal remains low, and freight charges moderate, the most promising field for the economic exploit of our vast peat lands lies mainly in the gasification of peat, and the utilization of its by-products, rather than the manufacture of briquets. In conjunction with such a plant, the making of peat mulch and peat straw, are industries that may meet with success if conditions are favorable.

Since the miner's certificate is so easily obtained, would it not be a wise safety precaution for the mine foreman or an assistant to go with a new man who is about to start as a miner, and see how he goes about preparing his shots and putting his place in order. It would be a difficult matter for any man, not versed in the art of mining, to hide his incompetency from an experienced foreman. Should the applicant be found incapable, the mine foreman should either employ him as a laborer or refuse his services altogether.

Up to the present time, the many mechanical and electrical arrangements which have been designed to dry peat cheaply, have all proved commercial failures. The only economical drying agents so far discovered, are the wind and sun. Could some scheme be devised whereby peat could be produced as a fine powder for dust firing, the field of this fuel would rapidly attain importance. There are only four works in Europe that manufacture solid peat briquets, and not one of these establishments has proved a great commercial success.

Mine managers should investigate carefully before they employ foremen or superintendents who have a reputation for producing the so-called "cheap ton" of coal. Many of these men, who are so much sought after, have a habit of reducing expenses by mining all the easily available coal, without devoting time or attention to future economic and systematic development. Such men remain with one company but a short time, and usually make it a point to change about the time the output starts to decrease and the cost begins to increase.

In the year 1650, at a colliery in North Wales, the general plan was to employ a man to enter the mine and fire the gas before the miners went to work. This man, who was called a "fireman," was dressed heavily, with his outer clothes thoroughly soaked in water. He carried a cane on which a naked lamp was fixed; when a doubtful or dangerous place in the mine was reached, he would lay down on the floor, or in a ditch, and then raise his candle to the roof and fire the gas. The historian states further that the fireman was seldom hurt. If the plan followed in 1650 were to be adopted at some of our gaseous mines today, it is probable there would be a great scarcity of firemen.

If we assume the average depth of all the peat bogs in the world to be 7 ft., then for this depth, every square mile would yield $7 \times 112,000 = 784,000$ tons (2000 lb.) of air-dried peat, and the estimated 200,000 square miles of bogs represent 156,800,000,000 tons of stored fuel. Considering that the heating value of the peat will average 4000 cal. per kg., or 7200 B.t.u. per lb., this is equivalent to 94,080,000,000 tons of coal of 12,000 B.t.u. per lb., or less than 4 per cent. of the estimated coal resources of the United States. Basing our figures on the present consumption of coal and lignite, without considering a future increase, our peat deposits would last about 75 years. The peat bogs in the United States would be exhausted in about 35 years if utilized as the sole supply of solid fuel.

The question of tamping shot holes in mines has recently been subjected to considerable discussion by coal engineers. The experiments of an English investigator show that owing to its inertia and friction on the side of the hole, tamping offers greater resistance to the escape of gases than generally supposed. This same authority has found that in a 1-in. diameter hole, 2 oz. or 4 oz. of powder would not blow out more than 7 in. of clay tamping, and that when the blast breaks out its burden, such tamping is often found intact in the hole. For high explosives, the 12 or 18 in. of tamping often used is unnecessary, as a few inches would often be sufficient. Many experienced shot-firers claim that in general, it is sufficient to use a tamping of water, or that a few inches of clay or paper pushed tightly home is all that is required. It will be interesting to hear what other authorities have to say on this subject.

The Pennsylvania law requires that all men who propose to become miners in the anthracite mines, shall first serve two years as a miner's laborer, previous to their appearance before the miners' examining board to obtain a certificate, which credential is necessary to their employment as miners. The intention of this law is often frustrated by the deception practiced by foreign miners. When a foreign laborer has been employed at some of our mines for two or three months, it often occurs to him that if he could only secure a certificate, he could mine coal as well as the man he is working for. The general plan followed is to have one of his friends of the same nationality, appear before the miners' examining board, and after giving the name of the laborer who desires the certificate, the more experienced miner answers the dozen or more questions propounded, pays his \$1.50 to the board, takes his certificate and sells the paper to his friend for the price agreed upon. Is it any wonder that mine accidents which so frequently occur, are often due to the ignorance of the miner himself?

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Pres and Treas. ROBERT MCKEAN, Sec'y.
555 Pearl St., New York.

London Office: 8 Bonville Street, London, E. C. Eng.
CABLE ADDRESS: "ENGINEERING," N. Y.

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs. Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for February, 1909, was 42,000 copies.

March 6..... 12,000

March 13..... 10,000

March 20..... 10,000

None sent free regularly, no back numbers.

Figures are five, net circulation.

The Situation in Copper

The statistics reported by the Copper Producers' Association last week for the month of February are not properly comparable on their face, with those for January because January was a long month and February a short one. Consequently, it is necessary to reduce to a daily basis. Upon such a basis it appears that the production in January averaged 3,617,265 lb. per day; in February, 3,703,600 lb. per day. This was a rather large increase; if maintained for a year it would amount to nearly 30,000,000 pounds.

The exports in January were 42,985,600 lb.; in February, 31,104,640 lb. Deducting these figures from the deliveries reported by the Association, it appears that American consumers in January took 47,376,821 lb., and in February, 43,441,974 lb. Computing the figures according to the working days in each month, the deliveries to domestic consumers in January averaged 1,822,185 lb., and in February 1,883,781 lb. So far as they go, these figures are encouraging, but they carry the metal only up to the gates of the manufacturers, and we do not know the situation inside of the latter. If we may assume that consumption is actually going on at the rate indicated for January and February, it must be recognized that there is a substantial improvement over the average for the whole of 1908, and that it is to Europe chiefly to which we must look for the great increase in demand to absorb the accumulating stock.

It was not to be supposed that production in February should exhibit a diminishing rate, inasmuch as the refineries were still working upon crude copper produced by the smelteries previous to Jan. 1. During February there was some curtailment by the miners who are unable to produce profitably on a 12½-cent basis, but even so it is doubtful whether their restriction is not more than offset by the increased production of Ely and other places that can produce profitably at a much lower figure. In this connection it is worth while to explain what is meant by cost of production. Sometimes the meaning is "direct operating cost." More conservatively, the meaning is the difference between gross proceeds and dividends to stockholders, which include all expenses for development, new construction, etc. Even so, the ultimate cost is an amount sufficiently large to reimburse the invest-

ment of capital. The allowance that should be made on the last account is difficult to determine for a variety of reasons. Moreover, in the curtailment of production there is a running expense on account of overhead charges which may make it cheaper to forego temporarily capital-return than to cease production entirely. Formerly, these conditions used not to be so carefully considered, but nowadays the talk that copper is cheap at about 12c. manifests not so much increased cost of production as compared with 10 years ago as it does the idea lurking in many minds that the capital invested in the production must receive an adequate return; in other words there is a better understanding of economics.

As to the outlook for copper in the immediate future, it is doubtful if the large sales that were made about March 1 help matters materially. Part of them were for speculative account, which does not assist at all; another part, representing the transactions with manufacturers, may not any more than make good the contracts that expired in February. It is quite obvious that there must be either a natural curtailment of production, or an increase in demand from home and abroad. Probably both those things will come into play and the market will naturally seek the level where demand and supply will balance.

Blast Roasting

Ever since the introduction of the Huntington-Heberlein, Savelsberg and Carmichael-Bradford processes there has been discussion as to the reason why they are so efficient in desulphurizing galena. Several years ago it was thought that lime played a chemical part in these processes, and ourselves leaning toward that belief we applied to them the generic name of "lime roasting." Later experience cast a great deal of doubt upon the chemical agency of lime, the function of the latter appearing to be to act as a diluent of the charge, and Prof. L. S. Austin introduced the name "pot-roasting" because the processes were then commonly performed in pots. Still later it developed that they could be done with other means, and A. S. Dwight used the term "blast-roasting." This will doubtless survive.

This progress in nomenclature marks the development in ideas as to these processes. Their results being so remarkable

in respect to rapidity and completeness of desulphurization and minimization of loss of lead and silver that it appeared to be necessary to attribute them to some undescribed chemical reaction. However, evidence gradually accumulated to show that there was nothing but an intensification of the ordinary reaction between sulphides and atmospheric oxygen, just as the combustion of coal on a grate is hastened by an under-grate blast, or indeed, the combustion of zinc sulphide (as in Bartlett kilns and the Greenawalt porous-hearth reverberatory). Indeed, we find the closest analogy in the blast furnace for smelting, which under certain conditions possesses a great oxidation-factor. Yet, the well known fact that the Carmichael-Bradford process, using gypsum, yields more sulphur dioxide than can be credited to the ore, has caused suspicion to remain that perhaps after all there is some reaction between lime, or lime sulphate, and the sulphides. So far as we were aware, calcium sulphate was not decomposed at the temperature believed to be attained in this process.

Prof. H. O. Hofman and W. Mostowitsch, in a paper in the *Bulletin* of the American Institute of Mining Engineers for January, 1909, report the results of an experimental investigation that clear up all doubts as to this matter. They have found that calcium sulphate begins to be decomposed at 1200 deg. C., but the dissociation is not complete until a much higher temperature is attained. However, silica begins to decompose CaSO_4 at 1000 deg. and the reaction is complete at 1250; while ferric oxide begins to decompose CaSO_4 at 1100 deg. and the decomposition is complete at 1250 deg., the product being calcium ferrite. The formation temperatures of calcium silicate and calcium ferrite are lower than their melting temperatures. Gypsum has no decomposing effect upon galena.

It is now established that in these processes the galena is oxidized by oxygen alone, but while the temperature in the ordinary oxidizing roast is but 900 to 1000 deg., in the blast roast it must be 1000 to 1250 deg. It has for a long time been recognized that the temperature of the latter roast is higher than would be implied by the low volatilization of lead, and it has been pointed out that the thermal action is localized as in the well-running blast furnace. However, although the older theories as to the formation of

calcium plumbate, or other compounds, in these processes have had to be discarded, the results of Hofman and Mostowitsch support the notion that there was some chemical action other than mere atmospheric oxidation. Inasmuch as gypsum is not decomposed at 1000 deg., the temperature of ordinary roasting, its presence can but have the effect of increasing the percentage of sulphur in the roasted charge. But at slightly higher temperature two important reactions occur, although lead or zinc play no part in either, whereby desulphurization is completed.

Metallurgists owe a great deal to investigations of this character, such as are being carried on in the laboratories of the Massachusetts Institute of Technology, Columbia University, and other institutions. They are beginning to reduce our knowledge to the precise basis of physical and pyrometric measurements and are rapidly furnishing data upon which new practices will be based. This is a line of work upon which the colleges should more and more concentrate their attention.

Steel Making in the United States

The production of steel ingots and castings in the United States in 1908 was less by a little over 40 per cent. than that of 1907, the decline having been rather greater than that in pig iron. The make of steel in 1908 was the smallest reported since 1901, with the sole exception of 1904, when the total was only 130,321 tons less than last year. The total make in 1908 was 13,897,627 tons, of which only 6,116,755 tons were bessemer, or converter steel, 7,780,872 tons being made in the open-hearth furnace.

Aside from the great decrease, the notable feature in the year's production was that the falling off in bessemer output was proportionally much greater than in open-hearth, the result being that for the first time the latter formed the larger part of the steel made. The proportion of converter steel to the total in 1908 was 44 per cent., which compares with 50.2 in 1907, and with 72 per cent. 10 years ago. Moreover, the smallest loss was in the basic open-hearth process, so that last year acid steel was only 49 per cent. of the total and basic 51; the proportions in 1907 having been 55.7 and 44.3, while in 1898 they were 82.3 and 17.7 per cent. Divided

according to the process used, the production of steel for 11 years past has been as follows, in long tons:

	Bessemer, Tons. Per Cent.	Acid- Open-hearth, Tons. Per Cent.	Basic Open-hearth, Tons. Per Cent.
1898.	6,609,017 74.8	650,880 47.6	1,568,412 17.7
1899.	7,586,354 72.0	862,800 84.2	2,080,426 19.8
1900.	6,084,770 65.3	855,044 8.5	2,545,091 25.2
1901.	8,713,302 65.2	1,037,316 7.8	3,618,993 27.0
1902.	9,138,363 61.6	1,191,196 8.0	4,496,533 30.4
1903.	8,692,829 59.6	1,084,908 7.6	4,753,913 32.8
1904.	7,859,140 67.1	801,799 5.8	5,106,937 37.1
1905.	10,341,375 55.0	1,155,648 5.8	7,815,728 39.2
1906.	12,275,830 52.8	1,321,653 5.7	9,658,760 41.5
1907.	11,667,549 50.2	1,269,773 6.5	10,278,315 44.3
1908.	6,116,755 44.0	826,301 5.0	7,084,568 51.0

Basic bessemer steel was never made in this country on a large scale, and has not been made at all since 1897. All the bessemer metal in the years given above was acid steel. In this table the small quantity of crucible and special steels, which has never reached 1 per cent. of the total, is disregarded. This production of crucible steel in 1907 was 145,309 tons; for 1908 it has not yet been reported, but probably did not exceed 110,000 tons. This would make the total output of steel for the year just over 14,000,000 tons.

The year 1909 may be expected to show a substantial increase over 1908, though there is now no probability—hardly even a possibility—that it will attain the high level of 1907. It is safe, however, to predict that there will be no great change in the proportions of the different classes of steel.

The preponderance of the open-hearth process may be expected to continue permanently, since it is based on the actual substitution of one process for the other, and not on any temporary condition. Thus, for instance, the steel made in the great new works at Gary will all come from open-hearth furnaces; and such furnaces have lately replaced an important group of converters in the Carnegie works at Pittsburgh. The bessemer converter has had an important part in industrial history, but it is gradually giving way to its later rival.

THAT CONCESSIONS in price do really stimulate consumption is illustrated by the recent experience of the American Radiator Company, which in 1908 realized the largest profit in its history. In their annual report the directors state that the lower selling prices established, because of reduction in cost of raw materials, induced a great number of people to purchase products for introduction in old buildings, and business from that source was largely increased.

The Anthracite Position

At the conference held in Philadelphia, March 11, there were present representatives of all the anthracite companies, headed by George F. Baer, president of the Philadelphia & Reading, and the United Mine Workers' committee, headed by President Lewis. The operators rejected all of the miners' demands. They also made a definite counter proposition to renew the present agreement for a term of three years, as in 1906. This means that the United Mine Workers must sign such an agreement before the existing agreement expires, on March 31, or take action upon the question of suspending work in all the collieries of the anthracite region. An official statement given out by Mr. Baer is as follows: "A committee of seven representatives of the Anthracite Mine Workers and a committee of seven representatives of the anthracite operators held a joint meeting to discuss the mine workers' demands. These demands are the same that were drafted in Scranton last October.

"The operators declined to accede to the demands. The chief reason offered for the rejection was that any increase in the cost of production would necessitate an advance in the price of coal, and that such an advance was impracticable. The operators said that the wages in the anthracite mining industry were already at a high level and could not be increased.

"The announcement of the operators' position was followed by a free discussion of the various demands, each side stating its views fully in regard thereto. The operators declared their unwillingness to reopen the eight-hour-day question and other questions passed upon by the Anthracite Strike Commission of 1902. They also declared themselves opposed to the mine workers' proposition for a one-year agreement.

"They declined to recognize the United Mine Workers of America, chiefly on the ground that it was controlled by bituminous mine workers. They said they met Mr. Lewis and his committee as representatives of the anthracite mine workers and not as officers of the union. The operators called upon the report of the Strike Commission to support their refusal to deal with the United Mine Workers.

"At the end of the discussion the operators made the definite proposition to renew the present agreement for a term of three years."

A second conference held on March 12 had the same result, and the committees adjourned with the understanding that another conference would be held after President Lewis, of the United Mine Workers, and his committee had presented the operators' proposition to continue the existing agreement for another term of three years to a convention of the mine workers.

Accordingly a convention of representatives of the miners in the three districts in the anthracite region has been called, to meet at Scranton, Penn., on March 23. All further conferences are adjourned until after this meeting.

It will be seen that the differences are wide. The operators declare that they are entirely uncertain as to the result, but they are determined not to give way, and not to surrender the open-shop principle, which has been the rule for three years. So far as trade is concerned, the season is approaching when domestic demand is light, and there are heavy stocks on hand, which will supply the trade for some time. Stocks of steam sizes are small, and a suspension would throw a large part of this trade to bituminous coal. Upon the whole, the conditions favor the operators, and they have on their side the support of the public, which cannot see the reason of the miners' demands, and is in no humor to submit to increased prices for coal.

The New Tariff as Proposed

The bill brought in by the Ways and Means Committee on March 17 makes the following changes:

Item.	Present.	Proposed.
Asphaltum, crude.....	free	\$3.00 per ton.
Fluorspar, crude.....	10%	0.50 per ton.
Fluorspar, refined.....	20%	1.75 per ton.
Boric acid.....	5c. per lb.	2c. per lb.
Borax.....	5c. per lb.	2c. per lb.
Bauxite, refined.....	0.6c. per lb.	0.5 c. per lb.
Ammonium sulphate.....	0.3c. per lb.	free
Alum.....	0.5c. per lb.	0.25c. per lb.
Soda ash.....	3c. per lb.	0.25c. per lb.
Sodium nitrate.....	2½c. per lb.	2c. per lb.
Salt cake.....	\$1.25 per ton.	\$1.00 per ton.
Sulphur, refined.....	8.00 per ton.	6.00 per ton.
Gypsum, crude.....	0.50 per ton.	0.40 per ton.
Gypsum, calcined.....	2.25 per ton.	1.75 per ton.
Iron ore.....	0.40 per ton.	free
Pig iron.....	4.00 per ton.	\$2.50 per ton.
Bar iron.....	0.6c. per lb.	0.4c. per lb.
Steel rails.....	5c. per lb.	3c. per lb.
Aluminum.....	8c. per lb.	7c. per lb.
Lead in ore.....	1½c. per lb.	1c. per lb.
Lead bullion.....	2½c. per lb.	1½c. per lb.
Manganese sand.....	6c. per lb.	4c. per lb.
Spelter.....	1½c. per lb.	1c. per lb.
Sheet zinc.....	2c. per lb.	1½c. per lb.
Zinc in ore.....	free	1c. per lb.

Refrigeration Applied to Mining

The application of mechanical refrigeration to mining operations, shaft sinking, etc., has been practiced (*Mining Science*, Dec. 10, 1908) in Europe for the last 25 years. In America, however, although well known, it has been little practiced, compressed-air methods being more favored. For instance, in 1906 there were about 56 shafts sunk in other countries by this method, while in America there was only one.

The field for this system of operation is much the same as that of the compressed-air method, i.e., working through quicksand or strata of gravel impregnated with water. Each system, of

course, has its special advantages and adaptabilities. For instance, the compressed-air method is superior for laying foundations under water by the caisson system, or for penetrating impregnated strata where rapidly flowing water is encountered which would tend to carry away partially frozen material. On the other hand the refrigeration method is better adapted for working to depths where compressed air may not be efficiently used on account of the injurious effect of the pressure upon workmen. With high pressures used in working to considerable depths frequent changes of shifts are necessary and much time is lost. In such cases the ventilation is liable to be unsatisfactory, leakage enters as a large factor of loss and the danger of a serious blow-out must always be faced.

In Europe the refrigeration method is mostly used in sinking in coal, iron and salt mines. In salt mining it is least efficient owing to the fact that the water impregnated with brine necessitates exceedingly low temperatures to produce freezing.

METHODS OF WORKING

The methods of operation practiced are modifications of the Poetsch system. In one system employed small holes are sunk around the periphery of a circle to inclose the proposed shaft. In each of these holes two pipes are lowered. The larger is closed at the bottom and into this the shorter one, open at the bottom, is lowered. The original lining of the holes is then drawn, the pipes connected, the outer to the brine or ammonia supply and the inner to the exhaust. Freezing of the surrounding material is then effected and the shaft is carried down within the inclosed circle. Afterward steam or hot brine is turned in the pipes to thaw out the ground and to facilitate their removal. The great disadvantage of this system is that, as with a diamond drill, the pipes sometimes depart from the desired direction entering the proposed course of the shaft.

Another development of this same system is in many cases more desirable. Shorter lengths of pipe are used connected by flexible joints with a central receiving head divided into two chambers, one the supply connected with the outer pipes, the other the exhaust connected with the inner pipes. The refrigerating material in circulating through the system freezes the surrounding ground. The core is excavated, lining inserted between the tubes and the lining completed while the tubes are again sunk to their full length. The points of variance between this and the first case are in the fact that the work progresses in stages and that a removable receiving head is used; thus shorter lengths of pipe are required and the danger of their deflection is reduced.

Comments on Questions Arising in Technical Practice and
Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

A Novel Stadia Rod

Mr. Granberry's article in the JOURNAL of Feb. 27, 1909, on stadia measurements recalls some work I did in the '70s, using stadia measurements in running several thousand miles of lines to make a topographical map of several hundred square miles. My rod was made in 7-ft. lengths, jointed, feet marked in black, and tenths painted alternately red and white, the rod being $3\frac{3}{4}$ in. I forget who told me to use looking-glasses, but I had pieces of looking-glass cut 0.1 ft. long and inserted them in the rod in the 0.9-ft. mark, the number being painted above the foot mark. With an intelligent rodman any distance for which the rod was long enough could be measured without trouble.

A "kink" I worked out proved a great time-saver in the field, and with care was just as accurate as the vertical-angle calculation for difference in elevation. It was as follows: After reading the distance on the rod and recording the vertical angle, bring the telescope level, note with the eye a piece of dirt, branch, or any object that the middle cross-hair cuts, bring the lower cross-hair up to this object, note by eye the point where the upper cross-hair cuts. screw up the telescope until the lower cross-hair cuts this new point, continue this until the upper cross-hair cuts the rod, note the reading on the rod of the upper cross-hair, then the difference of elevation is the stadia reading multiplied by the number of times the telescope has been moved up less the reading of the top cross-hair.

Thus, suppose stadia reading is 7 ft. = 700 ft. distance, that the telescope has been moved up eight times and then the top cross-hair cuts the rod at 4 ft., then

$$7 \times 8 - 4 = 52 \text{ ft.} =$$

height of bottom of rod above instrument. If the rod is lower than the instrument, bring telescope level, work down until bottom cross-hair cuts rod and add this reading. Thus, distance as before, but lower cross-hair cuts rod at 16-ft. mark; then

$$7 \times 8 + 16 = 72 \text{ ft.} =$$

height of bottom of rod below instrument.

In plotting topography in the field this will be found much the quickest way to get the difference in elevation, and it is also a check on the vertical angles. There are times, of course, when it cannot be used, as when the level line cuts above the sky line, or when a grain field is cut by

the cross-hairs. With good points to look at I found it to check up on the vertical-angle readings and only calculated vertical angles at night or on rainy days to check up the work. The only way to take topography with stadia is to plot the contours in the field; everything that saves time helps.

Another pointer for the beginner is: In taking vertical angles, sight at any convenient foot mark on the rod, record the vertical angle and under it put the foot mark with the prefix + or -, depending upon whether the rod is lower or higher than the instrument; thus, vertical + 5 deg. - 3 ft., or - 10 deg. + 6 ft.; the 5-deg. angle was taken to the 3-ft. mark and the 10-deg. to the 6-ft. mark on the rod; these feet to be added or subtracted from the calculated elevation.

Two good men in clear country should easily run 10 miles a day of stadia lines and put in the topography. A good rodman, however, is essential. I think Mr. Granberry's rod would be improved by inserting looking-glass at every foot mark. I do not see the necessity for the fine markings; tenths of a foot, I think, are all that are required except for quite short sights.

R. H. SANDERS.

Philadelphia, Penn., March 10, 1909.

Diamond Mine in Pike County, Arkansas

The letter appearing in the JOURNAL of Feb. 13, 1909, under the above heading and written by Dr. John C. Branner, from Stanford University, Cal., in criticism of my article on an "Arkansas Diamond Mine," which appeared in the JOURNAL of Jan. 16, 1909, seems to require an answer from me.

Taking Doctor Branner's criticisms in the order in which they are written, it appears that the fundamental trouble with my article lies in the unfortunate statement that Doctor Branner scouted the idea of the igneous mass containing diamonds. This, Doctor Branner admits to be true in his letter, but explains that he did so deliberately to keep people of Arkansas from going crazy.

The fact that I attributed Doctor Branner's skepticism (for in the absence of his letter of explanation it can be taken as nothing else) to a wrong reason, which Doctor Branner corrects by the true quotation from his own report, seems to me to refute his accusation of my having re-

peated most of his geology, for had I done so, I certainly would have made no mistakes and would certainly have given him full credit for same, as was done in the case of other authorities quoted in the article.

I first visited the Arkansas diamond field in June, 1908, for the purpose of making a report on same. While in Little Rock, the president of the Arkansas Diamond Company showed to me a copy of the report of the Arkansas Geological Survey containing Doctor Branner's and Doctor Brackett's reports and descriptions of the igneous area. I read these reports through hurriedly and glanced at the appended map, this being the only time I had seen the report or, to my knowledge, the map, until after the publication of Doctor Branner's letter.

As full geological reports had already been made by competent geologists in the employ of the Arkansas Diamond Company and others, and I had been employed to report on the engineering and economic possibilities of the field, the geological features were not of as much interest to me at that time as they might otherwise have been.

In regard to the geological portion of my article, the only part of it that was not written from my own personal field observations is the paragraph relating to the enclosing or country rock of the igneous area. This information was pieced together from several different reports and articles on the region, and it would have been difficult to give credit to any one of them, and was, therefore, published as general information. These reports may have been partly or wholly based on Doctor Branner's report.

As to the map in question, Doctor Branner certainly has justification for his claim. This map was given to me by the Arkansas Diamond Company with the information that it had been made by persons in their employ, which is absolutely correct, except that no mention was made of the fact that the volcanic outline, as determined by Doctor Branner, together with Doctor Branner's geological key, had been traced on the map to show the relative position of the area as determined by Doctor Branner and as determined by their survey. This fact I was not aware of until after the publication of Doctor Branner's letter, when I procured as soon as possible a copy of Doctor Branner's report and map and checked up both carefully. I am very sorry that the map was published without due acknowledgment

to Doctor Branner and hope that he will accept my apology for having done so.

In regard to my footnote relative to not finding diamonds in the *true matrix* in South America, I will leave that question to specialists in geology to fight out among themselves. A similar footnote or reference will be found, I believe, in *The Mineral Industry* for 1907. A discussion on this subject would prove interesting.

In conclusion, I beg to assure Doctor Branner that I had no such childish intent—appearances from his viewpoint to the contrary—to elect him "IT," nor do I pose as the "one gallus" man who first realized the possibilities.

JOHN T. FULLER.

Murfreesboro, Ark., March 1, 1909.

Firing Shots from the Electrical Power Service

D. Harrington's interesting account in the *JOURNAL* of the system of firing shots by electricity at the Utah Fuel Company's collieries, reminds me of the experiments that were carried out in the United Kingdom in the early days of electric lighting. In those days the electrical pressures did not exceed 110 volts and many things could be done with impunity that would not be practicable in these days, when pressures of 3000 volts are employed underground in collieries.

At the collieries where the system was carried out, an iron wire was connected to the end of one of the electric-light cables, and was carried into the workings, upon earthenware insulators. To fire a shot, one of the fuse wires was connected to this iron wire, and the other wire was pushed into the shot hole. In those days there was usually sufficient "earth" or "ground," as it is so much more expressively called in America, to complete the circuit through the fuse, when a switch, placed in any convenient position, and inserted in the iron wire, was closed. In addition to this, at one of the collieries, at least, where shot firing from the electric-lighting service was carried out, the electric engine-plane signals were also worked from the lighting service.

So far as I know, no serious accidents took place, but in Yorkshire, where it was tried, there were complaints of serious shocks being received from the rails, at some distance from the shot holes. In the collieries where the signals were worked from the electric-lighting service, it was very common to see flashes of light, similar to those one sees between the wheels of a tram car and the rails, at different parts of the engine-plane roads, produced by broken signal wires making contact with the rails, and then being pulled out of contact.

The arrangement described by Mr. Harrington avoids a large number of difficulties inherent to any method of firing

shots, or working signals from the power service. The precaution of disconnecting the shot-firing service from the generator, at all times except at the instant of firing, is exceptionally good. It insures, if the regulation is carried out, that the shot firing service itself cannot give shocks as long as its insulation is perfect. The provision also, of switches controlling the different branches, and still more, locking the switch cases, so that they cannot be interfered with, is of great value.

There is one danger, however, remaining, and that is the possibility of the shot-firing service cables making contact either directly with the power-service cables, or with some other metal which is in contact with the power-service cables, and transmitting the killing pressure to some other innocent body of metal, nearer the face. This difficulty should be largely overcome, and apparently from Mr. Harrington's report of the absence of accidents, has been entirely overcome, by the careful system of inspection which has been adopted.

There is another point that I think should be mentioned. Already, even in main roads, there is difficulty in finding room for the cables necessary for distributing the power current, so as to insure them against accident. I am afraid that it would be still more difficult in the majority of cases, to find room for the shot-firing service cables, though it appears to me that the arrangement, if carried out, would be a very good one.

SYDNEY F. WALKER.

Bath, England, Feb. 20, 1909.

Tariff Notes

SPECIAL CORRESPONDENCE

A large number of additional briefs dealing with the duties on minerals and metals to be fixed in the forthcoming tariff bill have been filed with the House Ways and Means Committee. Among these are a lengthy argument from the Cleveland-Cliffs Iron Company, Cleveland, Ohio, submitting data regarding the cost of iron-ore production. According to this statement, the costs at points of delivery are as follows: At Lake Erie ports, \$3.06; Mahoning and Shenango valley points, \$3.71; Pittsburg and vicinity, \$4.11; western Pennsylvania points other than above, \$4.31; points east of the Alleghenies, \$4.56. From these figures the inference is drawn that any reduction in the tariff on iron ore should be made with extreme conservatism.

IRON AND STEEL

Briefs filed by pig-iron interests in Pennsylvania and Virginia are to the effect that any reduction in the tariff on pig iron will be disastrous, one concern—the Thomas Iron Company, of Easton,

Penn.—asserting that any serious change will eventually compel all manufacturers of merchant pig iron in the East to go into liquidation.

James Lord, president of the American Iron and Steel Refining Company, has submitted estimates of the cost of manufacturing refined bar iron. The cost of material is placed at \$23.75, and the cost of conversion—including labor, taxes, insurance, depreciation and replacement—at \$9.35, or, in all, \$33.10 per ton.

Powell Stackhouse, president of the Cambria Steel Company, submits a statement showing the cost of steel rails to his company. This is \$14.92 per ton for all purchased materials, supplies, ores, transportation, etc.; \$9.42 for labor in mining and manufacturing; administrative and selling expenses of about 56c. per ton; or in all, \$24.90 per ton.

LEAD

In a lengthy argument before the Ways and Means Committee, Vice-President Brush, of the American Smelting and Refining Company has undertaken to rebut the contentions of manufacturers of lead articles and others who are dissatisfied with the existing trade situation. Mr. Brush urges the retention of the duty of 1½c. per lb. on lead in ore, giving a protection of \$30 per ton. He argues that, were there to be a cut in the tariff, the effect would be to discourage not only lead mining in the Rocky mountain region, but all other mining as well. The precious metals, he points out, cannot be recovered from the refractory ores of the Rocky mountains except as lead is used as a base to collect the precious metals in the process of smelting. In this process there must be at least 10 per cent. of lead in the furnace charge. Thus, according to this argument the whole business of the Rocky mountain region would suffer from such a change in tariff duties as is referred to. Mr. Brush further sets forth that the present price of 4c. per lb. for lead is not exorbitant, as is charged by critics, inasmuch as the cost of production in this country, not taking into account the depreciation of the mine, is approximately 3½c. As regards the alleged bad treatment of the mining interests by the smelters, it is set forth that the contracts with the miners agree to pay the latter the market price for their lead, silver and copper the day that it is shipped. Hence, it is argued, the claim that the smelting company profits by manipulating the price of raw material must be without foundation. It is denied that there is general community of the lead interests through joint directorates or common ownership of stock as has been charged.

The great lowering in costs that has been lately so conspicuous on the Rand, South Africa, has been due mainly to improved efficiency in the labor.

- CLONCURRY COPPER MINING DISTRICT, PARTS I AND II. By Lionel C. Ball. Queensland Geological Survey, Publication No. 215. Pp. 42-379; illustrated. 6x10 in.; paper. Brisbane, 1908: Government Printer.
- THE GEOLOGY AND MINERAL RESOURCES OF NEW BRUNSWICK. By R. W. Ellis. Canada Department of Mines, Geological Survey Branch. Pp. 135; illustrated. 7x10 in.; paper. Ottawa, 1907: Printed by S. E. Dawson.
- ROAD MATERIALS OF SOUTHERN AND EASTERN MAINE. By Henry Leighton and Edson S. Bastin. U. S. Department of Agriculture, Bull. No. 331 pp. 56; illustrated. 6x9 in.; paper. Washington, 1908: Government Printing Office.
- THE GEOLOGY OF THE PERSIAN GULF AND THE ADJOINING PORTIONS OF PERSIA AND ARABIA. By C. E. Pilgrim. Memoirs of the Geological Survey of India, Volume XXXIV, Part 4. Pp. 177; illustrated. 7x10½ in.; paper, 5s. 4d. Calcutta, 1908: Geological Survey of India.
- TEXT-BOOK OF PETROLOGY. Fifth Edition, Revised. By F. H. Hatch. Pp. 404; illustrated. 5x7½ in.; cloth, \$2.80. New York, 1909: The Macmillan Company; London, Swan Sonnenschein & Co., Ltd.
- Contents: The physical characters of the igneous rocks. The constituent minerals of the igneous rocks. The classification of the igneous rocks. The distribution of the igneous rocks as illustrated by the British Isles.
- MINERAL RESOURCES OF THE UNITED STATES, CALENDAR YEAR, 1907. Part I, Metallic Products. Part II, Non-metallic Products. Pp. 743 + 897; illustrated. 6x9 in.; cloth. Washington, 1908: Government Printing Office.
- This book is more clumsy than heretofore for having been divided into two volumes. This is done in accordance with an act of Congress. Why Congress should have made such a prescription, or bothered itself about the matter, is beyond comprehension. However, the ways and reasonings of Congress are "things that no fellow can find out," as Lord Dundreary used to say.
- The book and the investigation of which it is the result cost the people of the United States about \$75,000. If it were not that the U. S. Geological Survey is able to stretch its organic law to cover almost everything under the sun, we should ask the director to explain under what guise of legality the public funds are spent on reports as to the mineral resources of foreign countries and diverse other matters.
- MAGNETIC DEPOSITS OF THE CORNWALL TYPE IN PENNSYLVANIA. By Arthur C. Spencer. U. S. Geological Survey, Bull. No. 359. Pp. 102; illustrated. 6x9 in.; paper. Washington, 1908: Government Printing Office.
- This is a record of recent work in an old district, the object of which was chiefly to ascertain new facts bearing on the origin of the ore deposits. The results, so far as this object is concerned, were rather disappointing, but the author has been enabled to give a good description of an interesting group of mines. The ore-bodies occur in masses at different points on a rather wide belt extending from the Delaware river west and south across Pennsylvania to the Maryland line. The ores are generally magnetite, with enough pyrite to make roasting necessary. The largest and best known orebody is at Cornwall; it has been worked over 100 years, and is still exploited on a large scale. Smaller bodies have been, and are still worked at Boyertown, Joanna, Fritztown, Warwick and Dillsburg, all having nearly the same character.
- INDUSTRIE DES METAUX SECONDAIRES ET DES TERRES RARES. By Paul Nicolardot. Pp. 435; illustrated. 4¾x7 in.; cloth, 5 francs. Paris, 1908: Octave Doin.
- The plan of this little book is to take up each of the secondary metals having industrial applications, and to give for each its discovery, distribution, preparation, properties, alloys, extraction, detection and estimation, products and use in the industries. The book contains an introduction dealing with the preparation of alloys of the secondary metals by the aluminothermic process and in the electric furnace, and the preparation of filaments for incandescent lamps. The metals are then treated in the following order: tungsten, molybdenum, vanadium, titanium, uranium, zirconium, yttrium, thorium, cerium, osmium, columbium and tantalum. Following is the appended matter, consisting of a list of the minerals referred to in the work, a bibliographic index, an index to the authors and subjects treated, and a systematic table of the contents.
- The work contains considerable valuable information, such as could only be obtained by a search through recent chemical literature, and, for this reason, is to be recommended to the commercial or practical man. However, some important omissions are noted. The processes of Glin are not mentioned, and beryllium, the oxide of which is used extensively in the gas mantle industry, is omitted, as well as iridium. The historical discussions, although not presenting other than well-known facts, are commendable. Contrary to the custom of most continental chemists, Nicolardot properly refers to the element discovered by Hatchett as columbium.
- Several minor typographical errors, fortunately unimportant, are noted. The arrangement of the references in an "index bibliographique," and not at the bottom of each page as they occur, is productive of some confusion and loss of time; but the comprehensive, yet condensed text, written in scholarly manner by an authority in mineral chemistry and metallurgy, renders the work so valuable that one forgets these lesser faults.

The National Conservation Conference

SPECIAL CORRESPONDENCE

March 5, the joint conservation committee provided for by the National Conservation Conference, which met some time ago, convened in Washington and began work in executive session. The committee as appointed by Chairman Pinchot includes (in addition to Mr. Pinchot himself) six members of State conservation commissions and three members of the National Conservation Commission. Representing the State commissions were J. H. Teal, Portland, Ore.; Paris Gibson, Great Falls, Mont.; W. K. Kavanaugh, St. Louis, Mo.; Frank Rane, Boston, Mass.; O. J. Salisbury, Salt Lake City, Utah, and W. H. Milton, Marianna, Fla. The National commission is represented by Senator Knute Nelson, Alexandria, Minn.; Newton C. Blanchard, Shreveport, La., and George C. Pardee, Oakland, Cal.

To this committee reports were transmitted giving the details of the work accomplished by the State commissions and other organizations of similar character. The committee began by attempting to condense these reports and to draw from them practical suggestions as to what can be done in the way of cooperation between the conservation movements in the several States. The final recommendations will be transmitted by the conference to the several governors and the President, and these officers will be urged to do what they can to secure united action of all organizations concerned with the conservation of natural resources.

Among other documents which are before the committee for its use are those growing out of the resolution adopted by the conservation conference upon the suggestion of Powell Evans, of Pennsylvania, who presented a resolution providing that members of the national organizations in attendance upon the meeting be invited to offer their advice as to how the movement could be made practical.

bearings are dust proof and packed with waste. The brakes are of the standard street-car, inclosed ratchet handle type.

The electrical apparatus consists of a Westinghouse No. 64 motor, with type R controller, inclosed resistance, circuit breaker and cut-out switch, and reversible spring-type trolley. The cut-out switch is operated from the platform, and when the operator leaves the platform the current is cut off. This is for safety and avoids accidents, particularly as these cars are operated under very close clearance conditions. The wiring is specially incased in water-tight conduits to protect against the gritty material, which sometimes wears

ATLAS BOTTOM-DELIVERY, ELECTRIC,
CHARGING CAR

the insulation. The cars have a capacity of 5 tons and run on a 36-in. track. The over-all length is 11 ft., the width 5 ft., and the height from top of rail to top of car 5 ft. 6 inches.

The cars are manufactured by the Atlas Car and Manufacturing Company, Cleveland, Ohio, and the electrical equipment by the Westinghouse Electric and Manufacturing Company, Pittsburg, Penn. They are now in use at such smelters as those of the Garfield Smelting Company, Garfield, Utah; Michigan Smelting Company, Houghton, Mich., and the Anaconda Copper Mining Company, Anaconda, Montana.

Geological Survey Appropriations

SPECIAL CORRESPONDENCE

In the session of Congress which closed March 4, appropriations for the Geological Survey turned out more favorably than was expected at one point in the progress of the bills. The general current allowances have, of course, been maintained, but certain special changes have occurred, as follows:

1. A reduction of \$150,000 in the fuel-testing appropriations of the Survey. This cuts the amount from \$250,000, the sum set aside last year, to \$100,000 for the coming year. Inasmuch, however, as it was expected that this appropriation would last only for one year on any basis,

the allowance of \$100,000 is regarded as an addition to, rather than a deduction from, the original appropriation.

2. An increase in the appropriation for topographic surveys to \$350,000. This has stood at \$300,000 during the past two years, but was \$350,000 during 1906 and 1907. The increase for the coming year is thus \$50,000.

3. An omission of the \$10,000 heretofore granted for palaeontological investigations.

4. A transfer of the palaeontological work to the division of geological surveys. The latter appropriation is, however, increased by \$25,000, raising it to \$225,000 instead of \$200,000, the figure for the past four years. Thus a net increase of \$15,000 has occurred on palaeontology and geologic surveys taken together.

5. An increase of \$10,000 in the appropriation for the investigation of the mineral resources of Alaska making this \$90,000 instead of \$80,000, the figure for the past five years.

6. An addition of \$2500 to the annual rent allowances for the Survey. This permits an enlargement in the annex, which will be sufficient to allow the transfer of photographic laboratory of the Survey. This change is believed to be in the interest of more efficient safeguards against fire. At the same time it is held to furnish another argument in favor of the construction of a new building, inasmuch as every addition to the annual rent bill increases the economy to be realized by a new building. As to the building itself some progress has been made, although no favorable action was taken by Congress as a whole. The most that was accomplished was to get a favorable report from the House Committee on Public Buildings and Grounds. With another session's work the more hopeful friends of the Survey think that the desired provision can be pushed through Congress. In the course of the agitation in behalf of the bill its supporters received far more pledges of assistance than at any time in the past.

Correction

On page 399 of the JOURNAL of Feb. 20, 1909, in the 17th line from the bottom of column 2, the sentence reading: "The great plan in the argument of long life," etc., should read as follows: "The great flaw in the argument of long life."

The iron-ore properties in the State of Minnesota were assessed in 1908 at a total of \$176,340,749, or about 20 per cent. of the total real-estate valuation. The taxes paid on the iron lands amounted to about 15¢. per ton of iron ore produced in 1907. On the smaller production of 1908 they were nearly 25¢. per ton.

A Bottom-Delivery, Electric, Charging Car

The accompanying illustration shows a type of car in use in a number of the largest smelters and concentrators, known as the Atlas center-dump, swinging-door design. The door swings outward and is operated by the lever adjacent to the operator on the platform. The sides and ends are steep so that the material will not adhere, thus giving a clean delivery at all times.

The wheels are made of special material to withstand the hardest work, and are ground to insure maximum adhesion. The

The Calcium Nitrate Industry in Norway

Sam Eyde, in a recent lecture, described the status of the "saltpeter" industry at Notodden, in Telemarken, Norway. He traced the undertaking from its conception, and, throughout the experimental stages, to its present maturity under the auspices of the Badische Anilin und Soda-fabrik, whose rival method, together with capital requirements by the Norwegian promoters, necessitated an assimilation of interests. The Birkeland-Eyde nitrate industry at Notodden is epoch-making, in that it is the pioneer of its kind; from beginning to end it has been planned and carried out by Norwegians. Owing to breakdowns at the power station and factory, an average use of 13,000 kw. only was obtained in 1908, whereas the normal should have been 22,000 kw. In the last six months, allowing for occasional shortages of water, the average was 19,500 kw., with a revenue of about 1,500,000 kroner, and a cost of 970,000 kroner, which for the six months gives a net profit of 530,000 kroner. In experimental operations 1,000,000 kroner has been expended. The total capital in connection with the Notodden and Svölgefors construction was 11,000,000 kroner. The revenues will be further increased as soon as arrangements for the special production of ammonium nitrate and lime saltpeter, as well as the better regulation of the watersheds, are completed. Herr Eyde anticipates that with the further damming of the auxiliary falls, which would occupy 10 years, at a cost of 150,000,000 kroner, the yearly output of Norwegian nitrate would amount to 300,000 tons. Chile at present produces 1,800,000 tons annually—say, in 10 years' time (1920), 2,500,000 tons. As Norway's production in 1920 will have reached about 300,000 tons, to the value of 45,000,000 kroner yearly, it will only amount to about 12 per cent. of Chile's output in the same period. Chilean nitrate has to undergo a chemical process before it reaches the consumer, and climatic and labor drawbacks will in a high degree tend to prevent prices falling to a level that would threaten the Norwegian industry. Experiments with the practical use of Norway saltpeter have been carried out by authorities on agriculture in Norway, Sweden, Denmark, Germany, France, England and Scotland, Austria, Hungary and Italy, and results bear out the favorable opinion expressed by specialists on the first appearance of the fertilizer, viz., Norway saltpeter is equally as good as that from Chile; and in soil poor in lime it is even better.

The three companies connected with the Notodden-Rjukanfos power and nitrate production are: the Norwegian Power Company, capital 16,000,000 kroner; the Norwegian Saltpeter Works, capital 18,000,000 kroner; and the so-called Nor-

wegian Transport Company, capital 3,000,000 kroner, which was formed to connect Rjukanfos, Notodden and Skien by rail and water.

Technical details of the Birkeland-Eyde process now in operation at Notodden, and that of the Badische furnace method are not generally available, nor will it be known which of the two processes will be adopted for the Rjukanfos construction until the Badische process has been installed and tried in a factory now being built at Notodden.

Tomboy Gold Mines, Ltd.

SPECIAL CORRESPONDENCE

This English company operates a gold mine at Telluride, Colo. The report for the year ended June 30, 1908, records a profit of £87,115 on the last 12 months' working. Owing to the development of large bodies of comparatively low-grade ore in the lower levels, a policy was adopted of reducing the grade so as to yield profits of £5000 per month instead of £8000 per month. This policy aims at lengthening the productive life of the mine and maintaining a uniform rate of production in the future. The ore reserves at the close of the company's financial year were estimated at 410,000 tons.

Work has been carried on mainly on the Argentine group of claims, the Tomboy group having been operated by leasers whose output netted the company in royalties the sum of \$2153. The milling operations resulted in the crushing of 104,001 dry tons of ore from which bullion to the value of \$657,561 and concentrates worth \$341,459 were recovered. These amounts, together with \$13,482 received for boarding house, rents, royalties, etc., gave a total revenue of \$1,012,502. The expenditure on mining and development was \$340,553, or \$3.27 per ton; on milling, \$134,742, or \$1.29 per ton, and on general expenditure account, \$58,910, or 57c. per ton. The total expenditure was \$534,205, or \$5.13 per ton, leaving a surplus of \$478,296 on working account.

The manager, D. A. Herron, reports an interesting improvement in the treatment of middlings derived from the concentration of the ore in the mill. These middlings had formerly been a waste product. The new plant consists of classifiers, Wilfley tables, a roasting furnace and magnetic plant; and a separation of the iron, zinc and copper contents of the ore, with which some gold is associated, is effected. Zinc and iron concentrates of a marketable value are now produced. The plant was put into operation on Jan. 1 last. Experience has shown that the plant is capable of improvement and certain defects in the original design are to be remedied. The labor situation is reported to be now quite satisfactory.

The issued capital of the company is £300,000. For the year 1906-7 the dividend was 37½ per cent., and for 1907-8, 30 per cent. For the ensuing year it is proposed to hold in abeyance the development of the mine below the 2100-ft. level and to confine operations to the development of the orebodies indicated in a general way by the 1750- and 2100-ft. levels.

Mining in the Yukon Territory

SPECIAL CORRESPONDENCE

The report of the "Mining and Metallurgical Industries of Canada, 1907-8," states that the number of placer mines operated in the Yukon Territory on June 2, 1908, was approximately 7184. The Placer Mining act requires work to be done on each claim to the value of \$200 each year, but claims may be grouped so that expenditure on one or more claims shall be considered as covering all claims included in the group, and all the claims enumerated have been worked either separately or as one of a group. The number of quartz-mining claims in good standing in the Territory is approximately 1054. In the southern section extensive operations in copper and gold mining are being carried on. At Whitehorse a number of copper mines are in operation, and considerable quantities of ore being shipped. At Conrad considerable development in gold-quartz mining has been done with good results. There are 13 hydraulic mining locations in existence, comprising a total frontage of 38½ miles, which are all being operated in some degree. There are 58 dredging leases, comprising 304 miles of the submerged beds of rivers. These leases are confined to the Yukon, Forty Mile, Klondike, Stewart and Hootalinqua rivers. There were 12 large dredges in operation, nearly all having an indicated capacity of about 3000 cu.vd. per day, and it was anticipated that before the end of the season several others would be installed.

The only means by which the department can compute the production of gold in the Yukon is upon the amount on which royalty has been paid. The provision for the payment of a royalty came into force Sept. 11, 1897, and the records since that date show a total production of \$82,083,636. The maximum production was reached in 1902-3 with an output of \$12,113,015, each subsequent year showing a falling off, as will be seen by the following figures: 1903-4, \$10,700,663; 1904-5, \$8,222,053; 1905-6, \$6,540,007; 1906-7, \$3,304,791; 1907-8, \$2,820,161.

Two coal mines were in operation. The Tantalus, about 215 miles above Dawson produced last year over 7000 tons and the Sourdough, about 50 miles below Dawson, produced over 5000 tons. The coals retail at from \$15 to \$18 per ton.

Personals

Mining and metallurgical engineers are invited to keep **THE ENGINEERING AND MINING JOURNAL** informed of their movements and appointments.

A mail car containing a number of copies of **THE ENGINEERING AND MINING JOURNAL** of Feb. 27 was destroyed by fire in Illinois. Subscribers who have failed to receive that issue may obtain it by sending a postal card to this office. Our number of extra copies being small, subscribers will confer upon us a favor by making applications promptly.

Paul R. Forbes has returned to Mexico.

Allen H. Rogers has returned from Chile.

E. P. Mathewson, of Anaconda, Mont., has been visiting New York.

Richard A. Parker, Denver, Colo., visited New York and Boston last week.

S. H. Brockunier has returned to Wheeling, W. Va., from Alaska.

L. C. Church, of Joplin, Mo., has examined zinc-lead deposits at Alva, Oklahoma.

J. R. Finlay leaves New York this week for a trip to the Pacific coast, where he expects to be for about a month.

Henry C. Beeler, recently State geologist of Wyoming, has opened an office at Denver, Colo., as mining engineer.

F. C. Roberts has resigned his position as manager of the Ventanas mine in Durango, Mexico, and will return to San Francisco.

William C. Seddon, of Baltimore, has been chosen chairman of the executive committee of the Alabama Consolidated Coal and Iron Company.

W. E. Miller, of Glasgow, Scotland, secretary of the Arizona Copper Company, Ltd., is inspecting the company's mines and works at Clifton and Morenci, Arizona.

Douglas Muir has resigned his position as superintendent of the mill and cyanide plant of El Conde Mining Company at Tepic, Durango, Mexico, to take effect May 1 next.

Thomas Cox, formerly at Ely, Nev., and for some time past at Cerro de Pasco, Peru, expects to return to this country about June, and will open an office in San Francisco.

James L. Bruce, late engineer and assistant superintendent of the Grace Zinc Company, has been appointed general superintendent of the Continental Zinc Company at Joplin, Missouri.

F. A. Jordan has resigned his position as general superintendent of the Continental Zinc Company at Joplin, Mo., to take charge of an iron mine in the Moose Mountain district in western Ontario.

Robert Hawhurst, Jr., remains in Chile as general manager of the Poderosa Mining Company, Ltd., of London, which has recently acquired the properties of the Compañía Minera Poderosa de Collahuasi, Chile.

J. R. Dallas has resigned his position as engineer for the Leetonia Mining Company at Hibbing, Minn., to accept a position as manager for the Wheeling Gold Range Mining Company, at Sodaville, Esmeralda county, Nevada.

James Taylor has been appointed mine inspector for the sixth Illinois district, with office at Springfield. He succeeds Thomas Hannah, resigned. Mr. Taylor was formerly in Illinois, but for some years past has been managing a mine in Alberta, Canada.

C. A. Pringle, recently in Mexico, has been appointed manager of the Tintic Mining and Development Company's properties in the Bingham district, Utah. These include the Yampa smelter. He succeeds C. W. Saxman, resigned. J. C. Dick, general superintendent has also resigned.

George T. Oliver, just chosen United States Senator from Pennsylvania, was, until recently, engaged in the steel business. He was first vice-president and afterward president of the Oliver Wire Company until that company disposed of its plants in 1890. In 1889 he became president of the Hainsworth Steel Company and retained that position until its merger with the Oliver & Snyder Steel Company in 1897, of which he was president, until he disposed of his interest in the concern a few years ago.

Obituary

John Stevenson, superintendent of the Dunlap-Connellsville Coke Company, died at Hecla, Penn., March 6, aged 55 years. He had been employed in the Connellsville region for many years.

William McCully McKelvy died at Pittsburg, Feb. 28, aged 70 years. He was born in Pittsburg. He was president of the Alpha Portland Cement Company, a director of the Lockhart Iron and Steel Company, and of the Pittsburg Foundry Company.

James Robertson, Coatesville, Penn., died March 4, aged 48 years. He was superintendent of the open-hearth steel department of the Lukens Iron and Steel Company. He was a native of Glasgow, Scotland, came to this country about 24 years ago, and since then has been prominent in open-hearth steel practice, being connected with the above-named company since 1901.

John E. Carr, who died at Leavenworth, Kan., March 4, aged 69 years, was born in England and brought up as a mining engineer. He came to this country nearly 42 years ago. In 1872 he took charge of

a coal mine near Leavenworth, and was actively engaged in opening and managing coal mines in Kansas until his retirement a few years ago. He was the first man to put coal mining in Kansas on a paying basis.

George Everest, a miner, died recently at the age of 80 years, near Igo, in Shasta county, Cal., where he first went at the end of 1848. He had never since that time been outside of what is now Shasta county, and had continued mining operations all that period, never having followed any other occupation. While a record to the contrary would have been satisfactory, it is necessary to note that he died a poor man.

Societies and Technical Schools

Montana Society of Engineers—At the monthly meeting in Butte, Feb. 13, Victor C. Heikes, of the United States Geological Survey, with headquarters at Salt Lake, Utah, gave an interesting talk about the statistical labors of the Survey under his charge, within the district comprising Arizona, Idaho, Montana and Utah.

Canadian Cement and Concrete Association—The first annual convention and exhibition of this association was held in Toronto March 1-6. About 60 manufacturers were represented at the exhibition, which was opened by Hon. Doctor Reaume, Ontario minister of public works, who said that the provincial government had taken a leading part in introducing the use of concrete for bridges, dams, etc., and recommending it to municipal bodies. The convention proper met on March 2 and was largely attended. The opening address of President Peter Gillespie, Toronto, presented a comprehensive review of the growth of the Portland-cement industry in America. He urged the adoption of a standard form of specification for city contracts, and recommended the establishment of a government laboratory for the testing of materials. Dean Galbraith, of the faculty of engineering, Toronto University, said that with cement it was now possible to economize the wood used in building and conserve the forests. A large number of papers were read and addresses given. Among those who addressed the convention were A. W. Campbell, deputy minister of public works, Toronto; Emile G. Ferrolt, Philadelphia; Prof. E. Brown, McGill University, Montreal; J. E. Moore, Chicago; J. Augustine Smith, South Bend, Ind., and Charles D. Watson, Cleveland. Officers were elected as follows: President, Prof. Peter Gillespie, Toronto; vice-president, Gustave Kahn, Toronto; councillors, T. L. Dakes, Owen Sound, Ont.; Kennedy Stinson, Montreal; C. A. Lingham, C. Caniff, J. G. Murphy, D. Raymond and C. H. Thompson, Toronto.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at San Francisco, Butte, Salt Lake City, Denver, Toronto and Indianapolis

REVIEWS OF IMPORTANT EVENTS

San Francisco

March 12—While the State of California is producing nearly 50,000,000 bbl. of petroleum annually, it seems rather odd that some oil should also be imported. During the full months of last year 4,694,000 gal. of light oils, or tops, came into this port under the name of naphtha, from Singapore. It originated on the island of Sumatra. An export duty of 6 per cent. was imposed, and this country, to counteract that, imposes a 6-per cent. import duty. The light oil is used in the refineries on San Francisco bay in making illuminating oils, being added in suitable proportions during the process of manufacture of lighting oil from California petroleum. The California oils are mostly heavy ones, with asphalt base, and light oils are rather scarce.

The State Anti-Débris Association has received a surprise in having Yuba county cut off further money contributions. This association has been maintained by the counties of Yuba, Sutter and Sacramento, the supervisors of which contribute a monthly allowance. Yuba has been paying \$225 per month but at the last meeting of the board of supervisors it was decided to discontinue these payments for the future.

The mayor of Sacramento has announced that he will shortly call a convention to see what steps may be necessary to control or to stop dredge mining. Some of the newspapers are now calling on the engineers of the California Débris Commission to come forward with the necessary information about this industry. As it happens, however, this commission has nothing whatever to do with dredge mining, and has not studied its details. How the people at the proposed mass meeting are to get at facts when men interested in the subject, and having knowledge of it, are not invited to attend, remains to be seen. The dredge men have little fear of this since they can have exact facts brought out in court should litigation ensue.

The bill drawn by Senator Caminetti to appoint an advisory board of the department of engineering which might permit the building of impounding dams at hydraulic mines without going to the present expense of applying to the California Débris Commission, has been so amended that no final action can be taken without reporting to the legislature. It is also provided in the amendments that the courts have power to review the proceedings. With these amendments the bill has passed the Senate and gone to the

Assembly. The proposed law was intended to simplify matters for small hydraulic mines.

Salt Lake City

March 12—The United States Supreme Court has, for want of jurisdiction, dismissed the suit of the Mammoth Mining Company vs. The Grand Central Mining Company, which is generally construed as a victory for the latter company. The case which involved the question of apex, has been fought over nine years. A judgment of approximately \$170,000 stands against the Mammoth company.

For the week ending March 5, 184 cars of ore were shipped from the Tintic district. The following mines shipped in 20-ton cars: Colorado, 39 cars; Black Jack, 1; Beck Tunnel, 9; Brooklyn, 8; Dragon Iron, 34; Iron Blossom, 3; Swansea Consolidated, 1. The following mines shipped in 50-ton cars: Ajax, 9 cars; Horn Silver, 3; Silver Shield, 4; Bullion Beck, 2; Centennial Eureka, 46; Eureka Hill, 3; Mammoth, 1; May Day, 4; May Day concentrates, 1; Ridge & Valley, 2; Sioux Consolidated, 14.

Butte

March 10—Plans formulated some time ago for raising \$85,000 for the purpose of meeting option payments and paying off indebtedness of the Pilot-Butte Copper Company are meeting with an indifferent response from the stockholders. W. P. Jahn, president of the company, has recently issued another letter requesting response to the former appeal for subscriptions and calling attention to the loss which will be incurred in the event of failure to take up the option on the Pilot claim. He states that unless a payment of \$35,000 is made on the option from N. J. Beilenberg the company will lose the quarter interest represented by the option, on which several substantial payments have already been made.

In the action of Alonzo W. Evans against the Lake Shore Gold Mining Company, in which plaintiff secured a default judgment for \$10,123 some time ago, a satisfaction of judgment was filed by Evans a few days ago. Evans also filed a motion to set aside the judgment against the company, stating that his attorney had entered the judgment without his knowledge at a time when he, the plaintiff, was negotiating a compromise. Evans' attorney is now resisting the cancellation of the judgment on the ground that he has

a lien upon the same for the payment of his fee amounting to \$2263.

The Western Mining and Supply Company, of Butte, has brought suit against the North Butte Extension Copper Mining Company and the North Butte Extension Development Company for a sum slightly under \$1000 alleged to be due as rental for a pump used by the latter companies. An attachment has been levied upon the Black Crow, Overman, Occidental, Free Trade, Third Sphinx and Michigander quartz lode claims and the Clipper and Assay mill sites.

Denver

March 13—It does not seem likely that our State legislature will pass any laws this session looking toward the regulation of the smelters, and fortunately so, for it would appear better for these matters to be regulated by competition than by legislative compulsion.

A despatch from Salt Lake City today states that the Utah Mine Operators' Association has called for a conference to be held in that city March 25 by representatives from the principal lead camps of Utah, Nevada, Idaho and Colorado, the object being to devise means of protecting the lead-mining industry from the action of those who seek to reduce the tariff during the present session of Congress.

Goldfield, Nevada

March 9—The ore treated and shipped from Goldfield for the week ending March 6 was as follows: Nevada Goldfield Reduction Company, 685 tons averaging \$40 per ton; 50 tons from Pioneer at \$90 per ton; Consolidated and Combination mills, 4500 tons, estimated value \$40 per ton; Goldfield-Florence, 800 tons averaging \$20 per ton, and 225 tons shipped through Western Ore Purchasing Company the value of which is not made public.

Tonopah shipments: Tonopah Mining, 3150 tons; Belmont, 920 tons; Montana-Tonopah, 760 tons; Jim Butler, 300 tons; MacNamara, 235 tons; West End, 100 tons, and Midway, 100 tons. Total estimated value of \$135,000.

C. A. Gehrman, superintendent of the Florence-Goldfield, last week tendered his resignation, which was accepted. George Wingfield was elected president of the Goldfield Mining Stock Exchange March 3, to succeed H. T. Bragdon, who resigned on account of ill health. Mr. Wingfield's election was made at a meeting of the

board of directors after receiving a communication from him at Washington, stating that he would accept the position.

Senator Payne's bill providing for an exhibit and appropriation for the session of the Mining Congress to be held at Goldfield this fall, passed the Senate March 3, and has gone to the House. The law creates a commission of three who shall collect mineral exhibits from the various parts of the State and carries an appropriation of \$5000.

Indianapolis

March 15—The 20th annual convention of United Mine Workers of Indiana held a five-days' session at Terre Haute last week. Government ownership of coal mines as a solution of the problem of caring for disabled and worn-out miners was a proposition advanced by a number of delegates.

W. J. Woods, president of the Indiana Railroad Commission, addressed the convention, pointing out what the commission is doing to protect the lives of men employed about the railroad switches leading to the mines and elsewhere.

The convention emphasized the sentiment of breaking away from the old political parties and having labor demand that its own members represent it in public office. The miners are greatly disappointed over the rejection by the last legislature of bills introduced by labor interest.

W. H. Blatchley, State geologist, is in a quandary over the appointment of a State mine inspector. Under the new law 13 applicants took the first examination for appointment as State mine inspector and deputies and not one made the required grade of 85 per cent. Three of the number made grades of 80 per cent. The written examination covered questions relating to chemistry as applied to coal mining, mine engineering, and practical coal mining.

Among the applicants who failed to make the required grade were the present State mine inspector and his deputies, but Mr. Blatchley says the item of experience has not been sufficiently considered, and he believes when this is done a number of the applicants will have grades sufficient to comply with the law. Mr. Blatchley has submitted the matter to the attorney-general for an opinion.

Toronto

March 12—A return presented to the House of Commons at Ottawa, shows the approximate area of coal-mining lands in Saskatchewan to be 10,648 acres and in Alberta 373,691 acres. From payments for coal lands since Jan. 1, 1906, the government had received in Saskatchewan \$22,786; in Alberta \$1,116,413, and from coal royalties \$22,300 in Saskatchewan and \$23,514 in Alberta.

The situation in the Gowganda mining district during the early spring is likely to be serious, as between the breaking up of the winter roads and the opening of navigation some weeks must elapse, during which the new camp will be practically isolated. It is estimated that there are now upward of 10,000 people in the district, who unless extraordinary measures are taken to provide for them, may suffer for want of food. Every endeavor is being made to keep the line of communication open as long as possible and an immense quantity of freight is going into the country. The expense of freight is enormous, a rate of \$50 per ton being charged from Charlton to Gowganda. Teams are hired at \$15 per day.

The Canadian Pacific Railway has officially announced that, as soon as the frost breaks, a canoe freight route will be opened to Gowganda from a point on the line 35 miles west of Sudbury. As there are long stretches of lake navigation along this route, on which launches can be used, they will have, in addition to canoes, a number of launches for the heavier freight, putting horses on the portages to secure quick transshipment. The route is by way of Duncan lake, Shining Tree lake, Wapoose river and Montreal river.

Johannesburg

Feb. 25—Asbestos, of the chrysotile variety, occurs in many parts of South Africa, and the deposits of importance being opened up at present are situated in the Carolina district of eastern Transvaal, and the Victoria district, Rhodesia. The asbestos exported from Cape Colony is a fibrous amphibole. The Carolina company, controlled by one of the Rand's big houses, has issued a report showing that 281 tons of asbestos, mostly hand-cobbed, were produced during the last fiscal year. The profit of £20 may appear insignificant enough, but it compares favorably with the margin between revenue and expenditure declared by the majority of pioneer concerns floated in the outside districts during recent years. The crude produced is of good quality and 60 per cent. of it shows fibers over 1 in. long. Mining costs are naturally high, as the vein of productive serpentine averages only 2 ft. in thickness.

Yet another development record has been established. At the Van Dyk, in the East Rand, 323 ft. were driven in 62 shifts, with two 3½-in. Ingersoll-Sergeant machines. The ground, though deep, must have been especially favorable. Only 12 holes per round were required and each round, accounting for 5.21 ft. of average progress, required 44.3 lb. of blasting gelatine. It may be mentioned that the Brakpan company, which has done exceptionally speedy work in vertical and incline shaft sinking, is in the vicinity, and it would appear that the East Rand basin will, as a whole, be found cheaper

to develop than other parts of the field.

The year 1908 has been anything but a prosperous one in the South African diamond mines, yet the fascinations of the work hold a large community of adventurers to the alluvial of the Orange River Colony, Grigqualand West and the Transvaal. The relieving feature of the year's record has been provided by the new Harrismith diggings in the Orange River Colony. Mayer's Prospect has been proved rich and from a block 600 by 240 ft. in extent stones to the value of £30,000 are reported to have been won.

Paris, France

March 6—The study of the Lorraine coalfield has brought new facts to light. Borings undertaken at Gironcourt, near Mirecourt, have shown coal seams at a depth of 700 and 823 m. The first is 70 cm. thick, the second 60. Trias and Permian were only 270 m. thick at that spot, instead of 1020 m., as found by previous boring at Mont sur Menrthe. The belief is that it is the upper coal formation that has been struck. The coal producers in the north of France are striving to keep up the price of coal. The companies are divided into two groups; those that have joined the Douai Consortium and those that have not. The Consortium has lost ground in the East where German and Belgian coals are sold, but has succeeded so far in keeping up higher prices than the outsiders.

Official statistics of coal production for the departments of Nord and Pas-de-Calais show that the year 1908 holds the record, the coal mined being over 25,000,000 tons, against 24,000,000 in 1907. This result is remarkable since 1908 has been a poor year for the metallurgical industry. The output of both coalfields 10 years ago—in 1890—was 20,000,000 tons only. The advent of Belgian workmen is one of the chief factors in this increase. They bring in a reinforcement eagerly welcomed in France where the question of labor is often a hard one.

The Société des Gisements d'Or de St. Elie (French Guiana) made a profit of only 175,737 fr. in 1907-08. The company works its alluvial deposits of St. Elie and Dieu Merci on the leasing system, mines paying a royalty. In all, 244 kg. of gold have been saved, by the lessees. The Société des Mines de Zinc d'Ain Arko (Algeria) has just made its first report. On a capital of 1,500,000 fr. the profits amounted to 1,283,197 fr. This company proposes to pay 50 per cent. per share of 100 fr., having already repaid 25 fr. per share last year, and hopes to repay the balance of its capital at the close of the new year. It also expects to bring the output up from 12,000 to 15,000 tons. The concentrating mill built for dealing with calamine ores, which were not previously treated was put into commission in December last.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Alabama

BIBB COUNTY

At Centerville, recently, two of the men charged with firing into a train carrying non-union miners and guards at Blockton, during the strike last August, were tried and convicted. Mileto Papovitch was convicted of murder in the second degree and sentenced to three years at hard labor. Boris Dabovitch was convicted of murder in the first degree and sentenced to imprisonment for life. Both were defended by counsel employed by the United Mine Workers.

JEFFERSON COUNTY

The Alabama Consolidated Coal and Iron Company has filed a second mortgage on its properties to the amount of \$5,000,000. Part of the money will be used in redeeming some of the outstanding bonds and part in improvements. The company is said to have sold a large quantity of iron recently.

The annual meeting of the Sloss-Sheffield Steel and Iron Company was held in Jersey City during the past week. Despite the fact that there was a great depression on last year, a surplus was reported. The same officers and board of directors were reelected.

Alaska

Haines Mining and Milling Company—A Nissen stamp mill has been purchased for the mine back of Valdez. The officers report the possession of several ledges, the average value of which is about \$30 per ton.

Mother Lode—George E. Baldwin has been appointed superintendent. He was formerly with the Guggenheim interests in charge of the Bonanza mines.

Arizona

GILA COUNTY

Inspiration Mining Company—Stockholders voted to amend the articles of incorporation, changing the name of the company to the Majestic Copper Company.

Cordova Copper—Henry B. Hovland, Hoval A. Smith and associates have arranged for the merger of the Eureka group of claims and the properties now owned and under bond by the Globe Consolidated Copper Company. The new company will have a capitalization of 300,000 shares, par value \$10. One hundred thousand shares full paid Cordova copper stock will be issued for the 100,000 shares

outstanding full paid Globe Consolidated Copper Company stock. There will be issued 125,000 shares, \$2 first call and \$8 per share remaining due, subject to the call of the board of directors. Part of this stock will be exchanged for outstanding Globe Consolidated stock, and 70,000 shares unissued and under option will remain in the treasury. M. E. McCarthy will have charge of the property.

GRAHAM COUNTY

Graham County—March 5, 1909, the legislature of Arizona passed a bill which provides that Graham county shall be divided into two counties and that the new county, Greenlee, which contains most of the mines of the district, shall bear all of the bonded indebtedness of the present Graham county, amounting to about \$146,000. The new county is named for Mace Greenlee, the first prospector to explore the district. The southern half of the county will still be known as Graham county. The division takes effect Aug. 30, 1910.

Arizona Copper—Plans are being made to install an electric fire-alarm system at Clifton and Morenci. The production of copper for the month of February was 1273 tons.

Standard—A contract was recently closed with the Detroit Copper Mining Company whereby shipments of ore may be sent from Metcalf to Clifton via the Longfellow incline. The Arizona Copper Company will haul the ore from the incline to the smelter.

MARICOPA COUNTY

Future—Ten stamps of the old 80-stamp mill have been repaired and are now working on ore that is taken out in development work. Forty-five men are employed.

Arkansas

JOHNSON COUNTY

Little Rock Packet Company—This company, recently incorporated with a capital stock of \$200,000 by W. M. Kavanaugh and associates, has closed a contract with W. H. West, of Coal Hill, Ark., for the lease of 2000 acres of coal land in the Coal Hill district. The lease is for 10 years, and contains an option by which the company may purchase the property. There is at present a mine in operation, producing from 400 to 500 tons of coal per day, and it is the intention of the lessee to continue developments.

California

AMADOR COUNTY

Argonaut—A complete change of management has been effected. J. W. Lillenthal is now president; B. F. Taylor, vice-president; E. V. Zumbiel, secretary; R. S. Rainford, superintendent. Rapid development is now expected to take place.

Central Eureka—The work being done in reopening the shaft is within 400 ft. of the bottom and it is intended to sink much deeper.

Kennedy—At this extensive property, Jackson, a fine orebody has been found on the 3150-ft. level. Some of the rock being taken out is exceptionally rich, and the average values are as good as those when the mine was first discovered.

CALAVERAS COUNTY

Easy Bird and Peek Ranch—The people who have been bargaining for these mines have made first payment, and the deal has been closed.

Maine—At this old mine, West Point, a new shaft is being sunk by B. D. Porteous and D. O. Oliver.

INYO COUNTY

Estelle—This company is driving a tunnel near Keeler to cut a vein of silver-lead-copper ore. It will be 8000 ft. long and some 500 ft. have been driven. Machine drills are advancing the work at the rate of 10 ft. per day.

Lane—Reynolds & Peterson, of Darwin, are hoisting ore from the old workings of this mine.

Lost Burro—The first payment has been made. The operators will ship the high-grade ore while the mill is being built. Work will commence at once. The mine is in the Ubehebe district.

MARIPOSA COUNTY

Enterprise—At this property, near Hornitos, 12 men are at work taking out good ore, and the mill is kept at work steadily. New machinery is soon to be installed. F. H. McCall is manager.

SIERRA COUNTY

Snowden Hill—The new bedrock tunnel is being driven rapidly ahead and an upraise for the gravel will soon be made. The mine is owned by the American Mining and Development Company, and was one time known as the Jerry Watts placer. The property is seven miles from Camp-tonville.

Colorado

LAKE COUNTY—LEADVILLE

Vinnie—Another pocket of rich ore was recently taken from this property on Breece hill. The mine is worked from the Yak tunnel and the company has this month declared a dividend of 1 per cent., equivalent to \$5000.

Butte—During the week a two-foot gold-bearing vein was encountered in the tunnel.

Buckeye—This section lies to the northeast of Leadville and the little work that has been done on the surface shows that the formation is the same as that of Breece hill. Indications are promising.

Dinero—The present drawback to the successful working of the orebody opened last September in the tunnel is the water that accumulated in the old workings when the property was idle. This is being obviated by the driving of three upraises. At present the company is shipping about four cars of ore per week and the smelter returns show 50 oz. silver per ton.

Bartlett Tunnel—Preparations are now under way to drive this tunnel in Sugar Loaf district several hundred feet farther into the hill. A body of ore running high in silver has been opened in one of the drifts. The new company that took hold of the property recently is known as the George Nash Mining Company.

Cleveland—The shaft is now 785 ft. deep, leaving 40 ft. still to be sunk to complete the contract of 200 feet.

SAN JUAN COUNTY

Silver Lake—The electrical machinery at the mill has been completely overhauled and the mill will be started as soon as the crushing rolls are erected. There is a large quantity of ore in the bins.

Indiana

SULLIVAN COUNTY

A decree of foreclosure in favor of the First Trust and Savings Bank of Chicago has been entered against the Southern Indiana and Indiana Southern Coal companies. The mortgage indebtedness against the Indiana Southern Coal Company is \$1,500,000, and that against the Southern Indiana Coal Company is \$1,842,000. All of the properties of the two companies, including mines and lands in this and adjoining counties, are subject to the sale.

WARRICK COUNTY

A 6-ft. vein of coal has been discovered two miles southwest of Booneville. The vein is about 50 ft. below the surface and roof conditions good. The farm of 225 acres underlaid with this coal belongs to Henry Korf, of Evansville. This is one of the richest finds made in this part of the State for some time. The length of the vein is unknown, but it is believed to extend over considerable territory.

Michigan

COPPER

Quincy—The Pontiac or No. 9 shaft is down below the 300-ft. level and shows good copper-bearing rock. The land tributary to this shaft is being prospected by drifts from No. 8 shaft which are now within 800 ft. of the new shaft. The framework for a shaft house is on the ground.

Franklin—Sinking continues at No. 3 shaft on the Pewabic lode below the 700-ft. level. This lode is well mineralized at the drifts from the 22d and 23d levels of No. 1 shaft. All work on the Conglomerate lode is being centered in mining the previously blocked-out ore. It will take about a year to clean this all up.

Lake—Sinking continues at a depth of over 500 ft., and drifting is under way on the 410 ft. level. It is necessary to extend the workings to ascertain the value of the property.

Ojibway—The west bed of the Kearsarge lode opened at the 650-ft. level of No. 1 shaft is showing up well. At No. 2 shaft the crosscut from this same depth is nearing the lode and should encounter it about the same time that the shaft reaches the 800-ft. level.

Calumet & Hecla—The second portion of the regrinding mill will soon be ready to go into regular commission. Results that have been obtained from the first quarter of this mill are satisfactory.

Island Copper—This company has been recently organized under the laws of Michigan and will carry on operations in Houghton and Keweenaw counties, but principally on Isle Royal island. The company is capitalized at \$1,000,000 with 40,000 shares of \$25 par value, with offices at Houghton and Duluth.

Centennial—The annual meeting of stockholders will be held at Boston, Mass., April 6, 1909.

Missouri

ZINC-LEAD DISTRICT

Monticello—This company has incorporated with a capital stock of \$100,000 to operate the Monticello mine at Prosperity. F. A. Brown, R. K. Pitkin, the manager, and Byron Bourne, all of Joplin, are the stockholders.

Myrick—This mill, southwest of Joplin has been destroyed by fire.

Montana

BUTTE DISTRICT

Coalition—A station is being cut on the so-called 1700 level of the Tramway mine, which is in reality, about 1820 ft. below the surface. Production through this shaft averages between 600 and 650 tons daily, chiefly of ore mined from the

Minnie Healy ground. The 1300-, 1400-, 1500- and 1600-ft. levels are being worked, the greater production coming from the 1400- and 1500-ft. levels. An electric tramway carries the ore from the shaft to the ore bins, a distance of about 200 ft. The Rarus mine is producing about 850 tons daily.

DEER LODGE COUNTY

Southern Cross—Shipments of ore have recently been resumed. Twenty men are employed. With the advent of more favorable weather the stamp mill on the property will be put in operation.

Oro Fino—Anderson & Boscum have a lease on this claim, situated near Georgetown, and have shipped five cars of ore since the first of the year. The gold-bearing ledge is being worked through a tunnel.

FERGUS COUNTY

Barnes-King—About 120 men are employed. During the past 12 months the mine has been operating with a net profit of from \$1000 to \$5000 per month. The management states that during February the bullion produced amounted to \$25,000 and the operating expenses to about \$15,000.

The annual meeting of the stockholders was held at Kendall, Mont., March 3. The following directors were elected: John Gillie, C. W. Goodale, Donald Campbell, L. O. Evans and Phil. C. Goodwin, all of Butte; W. H. A. Fischer, New York City; John L. Bright and Wilfred Johnson, of Lewiston, Mont.

GRANITE COUNTY

Senate Group—An order of court has recently been made approving the sale of the property, situated in the Moose Lake district, to George M. Bourquin, of Butte. The sale was made by the executor of the estate of Ernest Cranmer.

JEFFERSON COUNTY

Corbin Copper Company—The management states that in the three tunnels on the Anna, Rosalie and Dewey claims, an average of 12 ft. advance is being made daily. About 50 men are employed.

Boston & Corbin—The shaft has reached the 700-ft. mark and is being enlarged from two to three compartments. A crosscut from this level will tap the vein 200 ft. below the present workings.

Raymond Mining Company—The property is situated three miles east of Clancy and carries gold and silver. The management states that they plan to resume operations early in the spring.

LEWIS AND CLARK COUNTY

Souvenir Gold—At a meeting of stockholders held last week the proposition of J. H. Simpson for a reorganization of the company was accepted. The present

company is capitalized at \$300,000 with 1,200,000 shares of the par value of 25c. each. The proposed company will have the same capitalization, but with 300,000 shares of the par value of \$1.

Nevada

CHURCHILL COUNTY—JESSUP

Rochelle Mine—A strike is reported on this property, owned by Messrs. Rice and Bailey. The vein, which is two feet wide, shows free gold. A shaft has been started and a hoist will be installed.

Eureka Mine—Messrs. Ratcliffe, Mack and Loose, owners of this group have a shaft down 130 ft. from which a drift has encountered ore. The ore is being sacked for shipment and a power hoist is to be installed.

ESMERALDA COUNTY—GOLDFIELD

Goldfield Consolidated—A strike of large proportion is reported on the 600-ft. level of the Mohawk. The vein is said to have a width of 40 feet.

Combination Fraction—The output was slightly over \$40,000 for the month of February. The mine is in good shape with a number of available stopes.

ESMERALDA COUNTY—ATLANTA

Fairview-Cherokee Lease—An 18-ft. ledge of quartz has been opened on the 500-ft. level. The ore is not of a shipping grade, but it is improving as drifting goes on.

ESMERALDA COUNTY—HORNSILVER

Orleans Mine—Small shipments continue regularly. The new, vertical, working shaft recently started, disclosed an ore shoot 10 ft. wide at the 65-ft. level, from which ore is now being taken. A gasoline hoist will be installed at once.

Hornsilver Mining Company—H. B. Taylor, of the Goldfield Engineers' Lease and Geo. B. Holleran will resume operations. The old hoist will be moved to the shaft on the Cable Lease, which will be sunk to the 300-ft. level before any laterals are run.

ESMERALDA COUNTY—RAWHIDE

Coalition Estate—There are now 40 leases in operation on this property. Ten are making regular shipments. Nineteen hoists are in operation and large bodies of milling and shipping ore are being developed.

LANDER COUNTY—HILL TOP

Hill Top Mine—This property is about 20 miles southeast of Battle Mountain. The first shipment consisted of two tons of selected ore that netted over \$2 a pound after deducting all expenses. The district is not yet three months old and already has several properties shipping. A controlling interest in the Hill Top was re-

cently sold to P. J. Queely, a coal operator of Rock Springs, Wyo., for \$110,000.

LINCOLN COUNTY

Pioneer Oil—Operations are at Indian Springs, about 20 miles from Las Vegas, Nevada. A drilling outfit costing \$6000 has been purchased and will be placed in service at once.

Nevada Oil—This is a new corporation, with a capital stock of \$100,000. The company owns 24,000 acres of oil land near Indian Springs. The officers are: Frank Oliver, president; F. A. Lucy, vice-president and treasurer; A. J. Sommers, secretary; Ira McFarland, general manager. Headquarters will be maintained at Goldfield.

NYE COUNTY—TONOPAH

Montana-Tonopah—The new refinery was completed last week and the first run was made March 3. The product representing a 15 day's cleanup was 21 bars of bullion weighing 90 lb. each. During the week 790 tons of rock were crushed, 235 tons of which came from the MacNamara. An unusually large amount of development work was performed during the week.

Jim Butler—S. H. Brady, formerly of the Belmont, was appointed superintendent of the property and took charge March 1, filling the vacancy made by the resignation of Alex Johnson. It is reported that extensive development work will be carried on from both the Stone Cabin and Wandering Boy shafts.

STOREY COUNTY—VIRGINIA CITY

Sutro Tunnel—The fire of two months ago resulted in great damage to the tunnel. A heavy cave has taken place destroying the stave pipe which was at that time being installed, thus seriously retarding the flow of water. The flume underneath the track, instead of being cleaned out by the greater pressure of water has become clogged and 50 men are now working six-hour shifts in the endeavor to remedy matters. At the time of the fire, the water was held below the 2450-ft. level, but now the 2400-ft. level is flooded and the water is still rising. An effort is being made to prevent its rise to the 2350-ft. level where there are a number of expensive pumps, hoists and other machinery.

New Mexico

GRANT COUNTY

Monte Cristo—Returns from the first shipment of ore from the Pearl mine at Sylvanite yield \$320 per ton. The Monte Cristo is a new company, the officers of which are: H. J. Bowles, president; H. W. Baylor, vice-president; D. W. Barnhill, secretary and treasurer; all of Uvalde, Texas.

Mogollon Gold and Copper—A reorganization has been effected. The new officers are Frederick M. Seward, Goshen, N. Y., president; W. B. Royce, Middletown, N. Y., vice-president; Frank P. Jones, Silver City, secretary and treasurer.

Grant County Telephone—This company has just completed its line to the Mogollon, connecting with all points of importance between that district and Silver City.

Oklahoma

PITTSBURG COUNTY

On Feb. 23 there was an explosion in mine No. 8 of the Rock Island Coal Company by which nine men were hurt. Later H. C. Booth, general manager; Robert Pickett, superintendent, and James Curran, pit-boss, were arrested and held for trial on complaint of Peter Hanraty, district mine inspector. He charged that the men were allowed to go to work there and to fire their own shots which, he says, was a clear violation of the law.

Oregon

JOSEPHINE COUNTY

Oriole Gold Mining Company—This company, capitalized at \$1,000,000, has just been organized; the home office is at Salem. The president is B. F. Rowland; vice-president and general manager, J. C. Mattison; secretary, O. S. Blanchard; treasurer, G. W. Donnell.

LANE COUNTY

West Coast—A gold brick worth \$5000 was shipped to San Francisco as part of the February cleanup. Ten men are now steadily employed in the mines; the future looks bright and prosperous. More men will soon be put to work blocking out ore in the tunnels.

The present company is the reorganization effected when the Oregon Securities Company failed. Mr. Ryan is superintendent.

St. Peters Creek—A. P. Churchill, owner, near Bohemia, has discovered an ore vein that pans well in gold. The property is only a prospect. The ledge is about 4 ft. wide. Its extent has not yet been ascertained.

Martin Creek—S. H. Burghardt, manager, reports some fine ore in the tunnels. Work has been in progress all winter, and it is reported that a plant will be installed in the early summer.

Combination—Good progress is being made with the development work, and as soon as the roads are better so as to make freighting possible they will build a concentrator. Some very rich silver ore has been found lately.

Golden Rule—Good work is being done on this property near Bohemia, and the company is now applying for a patent to its mining claims. It has made ar-

rangements for the capital needed to install a complete mining plant, concentrator and sawmill.

Pennsylvania

ANTHRACITE COAL

Philadelphia & Reading Coal and Iron Company—The statement for January and the seven months of the fiscal year from July 1 to Jan. 31 is as follows:

	January.	Seven Mos.
Earnings	\$3,072,526	\$20,305,684
Expenses	2,959,817	19,130,351
Net earnings.....	\$ 112,709	\$ 1,175,303

For the seven months there were decreases of \$3,838,845 in earnings; of \$3,011,298 in expenses; and of \$827,547 in net earnings.

BITUMINOUS COAL

J. V. Thompson, representing Pittsburg parties, has bought a tract of 5485 acres of coal land near Waynesburg, in Greene county. It is said that the land is to be developed soon.

South Dakota

CUSTER COUNTY

The mica mine of the Westinghouse Electric Company at Custer has temporarily suspended operations.

LAWRENCE COUNTY

Gold Eagle—A two-compartment shaft is being sunk on its main orebody. The shaft starts from the end of a 360-ft. tunnel and the contract is let for 500 ft. Crosscutting will begin at the 100-ft. level.

Golden Girl—Development work is shortly to be started. A number of prospect shafts will be sunk upon the exposed ledge in order to determine the best location for a permanent shaft.

Gold Dollar—This company expects to build a 100-ton cyanide mill, commencing work this spring. The property has been well developed.

Homestake—Preliminary work has commenced upon the 1700-h.p. hydro-electric plant at Spearfish creek. At least two years will be required for its completion.

Utah

BEAVER COUNTY

Mammoth—A drift from the 60-ft. shaft shows a 4-ft. ledge on a lime-granite contact. The ore carries lead, gold and silver.

SALT LAKE COUNTY

Dalton & Lark—The machinery is being overhauled and repaired and the pipe line over the hill will be placed in the Mascotte tunnel. It will probably be a month before the mine is in shape for active development.

Yampa—The smelter produced 5,500,000 lb. of copper during 1908. The plant is now producing about 1,000,000 lb. of copper per month at an estimated cost of about 8c. per pound.

SAN PETE COUNTY

Golden Reef—When the shaft reaches a depth of 250 ft., a crosscut is to be run to explore the vein encountered above.

Virginia

WASHINGTON COUNTY

Virginia Iron, Coal and Coke Company—Material for relining and otherwise repairing the blast furnace at Bristol has been received. The repair work will cost \$75,000.

Washington

KITITAS COUNTY

Skookum Copper—The Government has granted this company, operating in the Cle Elum district, permission to cut all timber required in constructing 16 miles of wagon road to the mine, and its new 250-ton concentrating plant. Work is progressing rapidly.

SNOHOMISH COUNTY

Wayside—This mine, near Granite Falls, under the management of Receiver Ned Hawkins, has encountered an orebody in the seventh level by a crosscut 12 ft. from the bottom of the shaft. The exposure shows 2 ft. of good ore. At the present time the deepest working is 500 ft. below sea level.

West Virginia

BRAXTON COUNTY

Cosmopolitan Coal and Coke Company—A controlling interest in this company has been sold to S. P. Boyd, representing Pittsburg parties. It is reported that the transfer is in the interest of the Steel Corporation. The company owns 11,600 acres of land in Braxton county, running over into Marshall county. It has a mine and coke plant at Gilmer.

Wisconsin

ZINC-LEAD DISTRICT

Highland—Jack and bone were struck at a depth of 37 ft. on the Whalen farm, two miles southeast of the village; the ore occurs in a disseminated vein and is a continuation of the Burrichter range. A deposit of white bone is being developed on the Manning property two miles west of Highland. In prospecting on the Tormey lot of the famous Crooked End, the Highland Mining Company struck 2 ft. of bone. This company is also prospecting on the Whalen 80, north of the village. Both of the company's mills have been idle for two months, but the smaller plant will start running next week. The Franklin

has opened up a rich deposit of bone on the Leuke tract; the company has over 600 tons of this ore in surface dump and will begin milling as soon as the weather settles.

Platteville—The Wisconsin Zinc Company will construct a mill on the Mitchell Hollow some time this spring; the ore has been crosscut 50 ft., the main sheet measuring 8 to 12 in. thick. The Gogebic, just west of the Kohinoor blende, will be opened up by shaft. The Homestead has completed its roasting plant. Over 500 tons of green concentrates are accumulated in the bin. Shipments from Platteville have been light the last three weeks, on account of bad roads. A few companies are holding for better prices, among them the Wisconsin Zinc Company, which alone has 1000 tons of green concentrates in bin.

Revee—*Miffin*—The shaft on the Ellsworth land reached the top of the pitch at 82 ft., showing lead and jack in sheet form. The Big Tom has completed shaft-sinking at 115 ft. and is following a 4-in. sheet of jack and lead toward drill holes which indicated a heavier deposit. The 50-ton mill on the Squirrel has been completed; the mine has a 14-in. sheet of jack. The Union Zinc Company has connected its new shaft and mill by 300 ft. of tram and will resume work in mine and mill. The mines in this camp which are producing regularly include the Coker, Sunrise, Senator, Gruno, Peni, Peacock and Slack; 50 per cent. of the production goes to the separating plants at Platteville and Galena.

Canada

ALBERTA

The population within a radius of 15 miles of Frank, in southwest Alberta, is estimated at between 9000 and 10,000. Farther north, within a similar radius of Bankhead, there is a population estimated at about 5000. In both districts coal mining is the chief industry, and its development in recent years has brought in the larger part of the population.

The joint meeting of representatives of the Coal Mine Operators Association of western Alberta and eastern British Columbia, and the United Mine Workers of America, recently opened at Macleod to formulate a new agreement to take the place of that to expire on March 31, has been adjourned until March 16, to allow F. H. Sherman, president of the local district of the mine workers to take an active part in the provincial election campaign now in progress.

BRITISH COLUMBIA

Official figures, compiled from returns received, show that the correct production of coal and coke in 1908 was practically as stated in the estimate published in the JOURNAL of Jan. 30. The revised figures show the production of coal to have been

1,678,000 long tons and of coke 247,400 tons.

The quantity of ore produced in the Boundary and Kootenay districts during the months of January and February was: Boundary district, 258,000 tons; East Kootenay, 17,000; West Kootenay—Ainsworth & Slocan, 16,500; Nelson, 9500; Rossland, 12,000; total 333,000 tons. This includes copper, gold and silver-lead ores.

Crows Nest Pass Coal Company—At the annual meeting held in Toronto March 12, sweeping changes were made in the directorate. G. G. S. Lindsey, president and managing director; Hon. Robert Jaffray, vice-president; E. R. Wood and Sir Henry Pellatt all declined reelection. The new board of directors consists of Elias Rogers, Toronto; Colonel Clough, New York; J. P. Graves, Spokane, Wash.; W. F. Robertson, Granby, B. C.; E. C. Whitney and H. B. McGiverin, Ottawa, and R. N. Young, Toronto. Mr. Young is secretary. It is understood that Sir Henry Pellatt has sold his large block of stock in the company to James J. Hill, so that the control now rests with the Great Northern Railway and the Granby Copper companies.

BRITISH COLUMBIA—VANCOUVER ISLAND

Two new coal ports are to be established on the east coast of Vancouver island—one at Boat harbor, about six miles north of Oyster harbor, which is the shipping port of the Wellington Colliery Company's Extension mines, and the other at Hardy bay, in the northern part of the island. The South Wellington Coal Mines, Ltd., George Wilkinson, Nanaimo, superintendent, has opened a coal mine near Nanaimo, and is installing a tippie of 1000 tons daily capacity, constructing a tramway seven miles to Boat harbor, and erecting bunkers and loading plant at the shipping point. The Hardy bay port is required chiefly for the shipment of coal from mines being opened in its vicinity, both on Vancouver and Malcolm islands.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ended March 6 were: Buffalo, 45,210 lb.; Chambers-Ferland, 60,000; Crown Reserve, 62,220; City of Cobalt, 75,000; Coniagass, 62,500; La Rose, 195,000; Nipissing, 38,410; Peterson Lake, 51,400; Temiskaming & Hudson Bay, 60,000; Trethewey, 60,000; total, 1,055,710 pounds.

Dividends—Recent dividends of Cobalt companies are: City of Cobalt, 3 per cent., quarterly, April 15, on the new capitalization of \$1,500,000. Crown Reserve, 6 per cent. quarterly and 9 per cent. bonus, March 31. Temiskaming, 6 per cent., quarterly, April 1.

Chambers-Ferland—In crosscutting at the 80-ft. level in No. 2 shaft a new Cobalt vein was encountered March 11,

which is 4 to 6 in. in width. Considerable high-grade ore is being extracted at the 150-ft. level of No. 1 shaft, where drifting north and south is being carried on.

Columbus—A 2-ft. body of galena has been encountered at a depth of 250 ft., and 51 ft. east of the shaft.

Hargrave—A tunnel is being driven in to cut a strong vein known as the West Center vein, being started about 100 ft. below the apex of the vein. A shaft has been put down 170 ft., from which a cross-cut will be run to strike the rich No. 3 vein of the Kerr Lake, which runs into the Hargrave location.

Station Grounds—This company has commenced operations from the main underground workings of the Cobalt Lake Company with power supplied by the latter.

Mexico

CHIHUAHUA

American Smelting and Refining Company—Three furnaces are in blast at the Chihuahua smelter. It is stated that owing to the diversion of ore hitherto going to the El Paso plant, makes necessary the early erection of two additional furnaces whereby the plant's capacity will be about 1250 tons daily.

Sau Toy—Shipments have been curtailed on account of fire destroying the lower tramway terminal and it will be several weeks before normal production will be resumed. During the last few weeks the average grade of the ore has been somewhat higher, due to opening the new orebodies.

Dolores—The recently published annual report shows the earnings for the year ending June 30, 1908, to have been \$260,359, the total income being \$863,096 and the total expenditures \$502,737.

Hidalgo—This Parral company has purchased the Nopal mine on the Veta Colorado lode. This acquisition is important inasmuch as it gives the company a mile of connected workings. Experiments are now being prosecuted with the view of erecting a cyanide plant. James I. and R. J. Long are at the head of the enterprise.

Mines of Mexico—Plans are announced for the installation of a large electric power plant utilizing the waters of the Mayo river in the Sierra Madre mountains. The company has a large mineral and timber tract in the Los Otates section. The control of this company is in the hands of Denver men, among whom are W. G. Boyle and W. O. Temple.

Mexican Northern Electric—This is a Canadian concern, lately organized in Montreal for the development of electric power throughout Mexico, and especially the La Joya site on the Conchos river. The largest stockholders are to visit Mexico during March.

International Oil and Gas—This Indianapolis company expects to begin active drilling operations on its concessions in eastern Chihuahua. The managing director, G. A. Deitch, general manager, A. M. Nelson and secretary, C. R. Troxel are now on the ground.

Sierra Madres—An unfortunate water shortage is reported in the western part of the state. The Otates and Santa Brigida mines have closed down and others, including the Rio Plata and Watertson, are using, to full capacity, their auxiliary steam plants. It is a number of years since so dry a season has been known and with the very light snowfall the indications are that the summer's operations at a number of mines must necessarily be curtailed.

Rio Plata—The report of January operations is as follows: Net returns on shipments, \$27,568; concentrates production, 60,190 ounces silver; operating expenses, \$8270; paid on account mine indebtedness, \$19,298, leaving a total mine indebtedness Feb. 1 of \$71,434. The power plant will be in readiness early in April when the completed cyanide plant will start on the accumulated tailings.

Parral Production—The output of the Parral camp for the week ending Feb. 26 was 9855 tons and for the following week 9390 tons. The February output was 45,000 tons as compared with 43,574 tons for January.

SONORA

Greene Gold-Silver—The directors, who are being sued by the New York State receiver to recover something like \$40,000 in dividends alleged to have been paid out of assets, have put the company into bankruptcy in West Virginia, where the concern is incorporated.

Martin Conboy of counsel for the directors said yesterday that the Federal bankruptcy proceedings would in no way interfere with the action of creditors against the directors. The directors in their answer to the New York State receiver's suit have taken the ground that in declaring dividends they acted on information of the company's condition supplied by Colonel Greene and the proper officers of the company, which they believed to be correct and given in good faith.

New Caledonia

Exports of ores from New Caledonia for December and the year ended Dec. 31 are reported by the *Bulletin du Commerce*, of Noumea as follows, in metric tons:

	December.	Year.
Nickel ore.....	5,118	120,028
Cobalt ore.....		3,406
Copper ore.....		10
Iron ore.....	10	64
Chromite ore.....		46,309

In addition there were reported for the year shipments of 5 tons lead and 5020 kg. silver.

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, March 17—The coal trade in the West is beginning to take on a more hopeful tone. This is a result of increased orders for steam coal which have appeared in some quarters. Mines are generally making better time, though shipments to consuming centers are still restricted in order to prevent accumulations which will reduce prices.

The bituminous trade in the East is beginning to wake up a little, though it is still inclined to be rather irregular. However, taken as a whole, an improvement is manifest and there is little doubt that more coal has been sold.

The anthracite trade depends entirely on the negotiations for a renewed agreement. Just now everything is in the air, and the miners and operators alike are uncertain whether there will be a general stoppage of mining or not. Opinions vary widely and there is really nothing to base positive predictions upon. Notes on the situation will be found on another page.

The coke trade has had rather a setback, the increase in production having called out a larger supply than was really needed at the present time.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to March 6, short tons:

	1908.	1909.	Changes.
Anthracite.....	941,066	838,722	D. 102,364
Bituminous.....	6,809,931	6,167,234	L. 287,363
Coke.....	1,302,635	1,739,560	I. 436,865
Total.....	8,113,652	8,795,466	I. 681,804

The total increase thus far this year was 8.4 per cent.

Coal and coke tonnage, Chesapeake & Ohio railway, seven months, July 1 to Jan. 1, short tons:

	Coal.	Coke.	Total.
New River.....	3,849,142	135,529	3,984,671
Kanawha.....	3,068,051	17,689	3,085,740
Kentucky.....	210,232		210,232
Connecting lines.....	151,995	44,489	196,484
Total.....	7,279,420	197,707	7,477,127
Total, 1907-08.....	6,855,741	224,860	7,080,601

Deliveries this year to points west of mines, 3,816,156 tons coal and 116,834 coke; points east, 995,101 tons coal and 80,873 coke; tidewater, 2,552,911 tons coal; anthracite to line points, 525,205 tons.

Shipments of coal for the year ended Dec. 31 from the Cumberland region—including the North Potomac basin—are reported as follows: Baltimore & Ohio, 2,554,779 tons; Pennsylvania Railroad,

354,613; Western Maryland, 1,886,257; Chesapeake & Ohio Canal, 190,336; used at mines and sold locally, 798,606; total, 5,784,591 tons. The total in 1907 was 7,360,336; the decrease last year, 1,575,745 tons, or 21.4 per cent. The largest shippers in 1908 were the Consolidation Coal Company, 1,938,569; Davis Coal and Coke Company, 1,765,789 tons.

New York

March 17—The anthracite trade is quiet so far as domestic sizes are concerned. The strike talk has produced much uncertainty, but everyone believes that the companies have sufficient stocks of the large sizes to carry them through. Steam sizes, on the other hand, are scarce and in demand. Consumers of these sizes are anxious to put in stocks ahead if possible, but the production has been moderate for some time, and the companies are holding back considerable quantities at the mines in order to be supplied with fuel for pumps, etc., in case of a stoppage.

The usual April discount of 50c. has not been announced and probably will not be until something definite is known. Prices continue nominally unchanged, but dealers and agents are getting from 5 to 15c. per ton advances on pea and buckwheat. The list prices for prepared sizes are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points.

BITUMINOUS

The soft-coal market is not exciting. There has been a little improvement, but it is irregular and trade is very bunched. Nevertheless, there is an improvement which is noticed most by the commission houses. Orders are generally for as quick delivery as possible, indicating that stocks are low. Some more contracting has been done, but slowly and with a good deal of dickering. A number of contracts are about 25c. below last year. The best trade just now is coming from the Sound, but the far East is reported to be pretty well cleared out of coal.

All-rail trade continues to hold its own fairly well. Transportation is fully up to schedule and car supply abundant. New York harbor is a little irregular, but prices remain unchanged at \$2.40@2.50, f.o.b. harbor shipping points, for good steam coal, with lower grades about 20c. less.

In the Coastwise trade vessels are

slowly coming out of winter quarters and captains are actively hunting for charters, which has brought about a decline in rates to a very low point. We quote for large vessels from Philadelphia: To Boston, Salem and Portland, 70c.; Lynn and Bath, 75c.; Portsmouth, 75c.; Newburyport, 80c.; Providence, New Bedford and the Sound, 55c. The peg of 75c. for around Cape Cod has at last been removed.

Birmingham

March 15—The coal trade in Alabama continues dull with no indications of an early improvement.

During the past week State Mine Inspector Flynn gave out some official figures as to the coal production in Alabama during 1908. A few mines are yet to be heard from which, it is estimated; will add about 500,000 tons to the figures now worked up. The figures in hand already total 10,474,591, against 14,424,863 tons in 1907. There were 118 men killed in the coal mines of Alabama during the year.

The coke production, which was reduced a few weeks since, will shortly be started up again, several batteries of ovens resuming operation shortly. The Tennessee company still has a large quantity of coke stacked up.

Chicago

March 15—Firmness exists in all branches of the coal trade. For steam uses both Western and Eastern coals find a quietly improving market; the domestic trade has dwindled to a condition of week-to-week supply. The market is notably bettered as to demurrage troubles. Little coal is depressed by reason of too great shipments and forced sales.

Contract business shows fair bookings to date, but the old trouble exists in the realization by consumers that retail prices will probably continue low because of large production and relatively small consumption. Fine coals show stronger tendencies with the advance of spring conditions.

Prices show little change. Illinois and Indiana lump and egg is quoted at \$1.75@2.40; run-of-mine at \$1.60@1.75 and screenings at \$1.25@1.55. Eastern coals show a firmer tendency; smokeless Pocahontas and New River lump bringing \$3.15@3.45 and run-of-mine \$2.85@3.15; lower-grade smokeless sells for \$2.95@3.30, lump or egg, and \$2.85@3, run-of-mine. Hocking coal has been withheld from this market, with the result that it is made firmer,

selling for \$3@3.15. Youghiogheny is quiet and steady at \$2.15 for 3/4-in. gas, and Pittsburg No. 8 brings \$2.75@2.85 for the same size.

Anthracite is very dull. The threats of labor troubles have not yet affected the market.

Cleveland

March 16—Prospects are not good for an early opening of Lake trade. Reports from the Northwest are that there are still large stocks of coal, which are being drawn on very slowly. Shippers are holding back on charters until they can get some line on probable demand.

Local coal trade is dull and there is a surplus supply, which has made prices weak. Eastern Ohio 3/4-in. can be had around \$1 at mine, and slack at 55c. Some sales of slack are reported at 50c. at mine.

Indianapolis

March 15—The most encouraging feature of the coal-mining industry in this State is the increasing demands for coal, which kept the mines running more regularly during the past week than for some time. This condition has occasioned the operators to become more optimistic. There is little or no fluctuation in prices and no attempt is made to secure large contracts by shading prices at the mines. The loss of a large amount of Pennsylvania coal by the sinking of barges in the Ohio river near Evansville, has occasioned quite a stiff demand for Indiana coal to supply the demand for lower river towns.

Pittsburg

March 16—Few mines in the district, outside of the river mines, are running more than three days a week, and production at the railroad mines in the district is estimated at about 30 per cent. of capacity. No large contracts have been made, and orders are for small tonnages compared to the buying formerly at this season of the year. Prices are being firmly held by the large producing interests on the basis of \$1.15 for mine-run coal at mine. This price, however, has been shaded by small operators. The river mines continue to run full, and there are plenty of empty coal boats and barges. Several tows were sent out during the week, cleaning up all the coal that was ready for shipment.

Connellsville Coke—There is no improvement in the trade. Lower prices are being quoted, but this has not induced buying. Sales of spot furnace coke have been made as low as \$1.50, but on contract the price is being held by large producers at \$1.75. Foundry coke for prompt shipment has declined to \$1.00, and it is believed contracts can be made at that rate until July 1; but the regular contract quotation ranges from \$2@2.15. The *Courier* gives production in both fields at 260,000

tons. The shipments were 9427 cars as follows: To Pittsburg district, 3138; to points west of Pittsburg, 5543; to points east, 746 cars.

Foreign Coal Trade

Austrian Coal Trade—Imports and exports of fuel in Austria-Hungary, year ended Dec. 31, metric tons:

	Imports.	Exports.	Excess.
Coal.....	9,995,289	768,445	Imp. 9,226,844
Brown coal (lignite).....	30,432	8,596,104	Exp. 8,565,672
Coke.....	861,098	183,278	Imp. 667,820
Briquettes.....	106,516	100,264	Imp. 6,252

Total..... 10,983,335 9,648,091 Imp. 1,335,244
Total, 1907... 10,538,619 10,140,841 Imp. 397,778

The total increase in imports in 1908 was 4.2 per cent.; the decrease in exports, 4.9 per cent.

French Coal Production—Output of the Nord and Pas-de-Calais—the two chief coal-producing districts of France—for the full year was, in metric tons:

	1907.	1908.	Changes.
Coal mined.....	24,738,628	25,521,605	1,782,977
Coke made.....	1,946,767	1,761,347	D. 185,420
Briquets made.....	1,191,297	1,339,817	I. 148,520

Of the coal mined in 1908 the Nord furnished 9,963,774 and the Pas-de-Calais 18,557,832 tons.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on March 6; Best Welsh steam, \$3.36; seconds, \$3.24; thirds, \$3.12; dry coals, \$3.48; best Monmouthshire, \$3.06; seconds, \$2.94; best small steam, \$2.10; seconds, \$1.86. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, March 17—The iron and steel markets generally have lapsed into rather a waiting condition. While price considerations have more immediate effect than the tariff revision, there are quite a number of buyers who deem it prudent to wait until something definite is known. No one expects that there will be any heavy importations of iron and steel, but the reduction of the tariff may have a considerable effect upon prices. The first draft of the new tariff bill, made public today, proposes large reductions in duties on pig iron and steel, and a removal of the duty on iron ore. These changes had been expected.

Pig iron has been more active and quite a number of contracts have been placed for foundry and basic. These are being generally taken at a reduction, mostly for immediate delivery, very few of them running beyond June. Southern furnaces have been rather scrambling for orders, and several contracts have been reported taken at \$11.50 and even \$11 Birmingham, for No. 2 foundry. On the other hand, some of the large companies have declined to take less than \$12, Birmingham. Virginia furnaces have also cut the prices, but Northern merchant furnaces are rather inclined to hold back

Finished material has been only moderately active, with the exception of structural steel. A number of contracts have been placed for building material and there seems to be a general disposition to go ahead with bridge and building projects.

The Pennsylvania and the Maryland steel companies have announced reductions of 10 per cent. in wages. It now seems probable that other companies will follow the same course. The Steel Corporation has made no announcement as to its intentions.

Iron-ore Movement—Imports and exports of iron ore in the United States, month of January, long tons:

	1908.	1909.	Changes.
Imports.....	67,659	105,233	I. 47,574
Exports.....	5,463	4,225	D. 1,238

Of the imports this year 70,525 tons were from Cuba; the balance from Newfoundland and Spain.

Imports of manganese ore in January, 35,019 tons in 1908, and 14,942 in 1909; decrease, 20,077 tons.

Baltimore

March 10—Exports from the port of Baltimore for the week included 876,646 lb. scrap tin to Rotterdam. Imports included 1601 tons ferromanganese and 125 tons manganese ore from Liverpool; 119 tons manganese ore from Rotterdam; 7581 tons pyrites from Spain; 10,100 tons iron ore from Cuba.

Birmingham

March 15—There is a better sale of iron going on in the Southern territory, but the market is still quiet. There is some improvement noted. Quotations are still weak—\$12 per ton, No. 2 foundry—but hardening, though there is a report that one or two companies are still selling under that figure. One or two companies are holding out for \$12.50 per ton. The cast-iron pipe concerns in this territory have a large amount of business in hand and have recently received other orders that warrant a steady operation through the balance of the year and longer. The pipe makers have been the best patrons in the last few months of the Southern furnaces. There has been no reduction in the make of iron in this district.

All kinds of reports are current in reference to the Ensley steel plant of the Tennessee company, shutting down April 1. There is no denial or verification. There is some accumulation of steel, though it is understood that the rolling mills of the company at Bessemer, Ala., will resume operation shortly and will use considerable steel.

Chicago

March 15—The iron market is gradually assuming confidence as regards manufactured products, and is buying well. As regards pig iron only slight improvement is

visible; the ordinary consumer prefers yet to buy from hand to mouth. He will not take, as a rule, more than a carload to 200 tons at a purchase, and he will not buy even so small an amount unless he can see use for the iron within the next three months. This condition seems bound to continue, for the subject of tariff legislation seems to be uppermost in the minds of all melters of iron. They are speculating little on possible changes.

Prices remain vague. Some Southern iron is said to have sold below \$12 Birmingham (\$16.35 Chicago), but that figure is still quoted nominally and doubtless represents some transactions. Northern at \$16.50 remains firm in general; special contracts may receive lower quotations, but not the average consumer. Business for the second half is generally regarded as non-existent. Lake Superior charcoal sells for \$10.50, with fair demand.

Coke is somewhat firmer, the best Connelleville bringing \$4.85 with shipments well held down.

Cleveland

March 16—Nothing definite has yet been done about ore prices. Some small sales have been made by an outside interest at last season's prices, but this is not considered as of importance, so far as the general market is concerned.

Pig iron is dull, and only some small local sales have been made, chiefly of foundry. Prices have been around \$16, Cleveland, for No. 2 foundry, and \$14 for gray forge.

In finished material business is growing, and a number of transactions are reported. Individual orders are not large, but the aggregate is increasing considerably.

Philadelphia

March 17—The past week has been almost lifeless, so far as pig iron is concerned. A few of the larger consumers, among which were several foundry interests, made propositions a week ago to buy special iron but withdrew them suddenly. Makers of pig iron are showing a desire to secure business, but are not able or willing to make any further concessions than those announced two weeks ago. The forge iron buyers are absolutely out of the market.

Steel Billets—The reduction in steel billets has led to the opening of negotiations or inquiries as to how far ahead manufacturers will be willing to make deliveries if orders are placed at this time.

Bars—Steel bars have been selling somewhat better within the past week and mills are now running on fair sized orders. There is also some additional business in common iron for the general trade; refined is weak and quotations are 1.45@1.50c. Common has sold as low as 1.20@1.25c., tidewater.

Structural Material—Apart from some

little inquiry nothing of importance has been done in this market in structural material.

Scrap—There is no activity and stock is accumulating. Several dealers are making efforts to get all the heavy cast scrap and railroad scrap they can get. Prices are weak.

Pittsburg

March 16—The unexpected determination of the Steel Corporation, through its tinplate subsidiary, to cut prices \$5 per ton which was reached during the week after a careful consideration of the situation undoubtedly will prove of benefit to that interest. The independent concerns, however, were opposed to the cut and contend that it will seriously affect their trade unless a corresponding cut is made in tinplate bars. The recent cut in bars was but \$2 per ton, making the price \$25.50 delivered in Steubenville. Wheeling, Sharon, McKeesport and adjacent territory. If this rate is lowered it will be necessary to reduce steel billets, the price of which was fixed at \$23, Pittsburg. To lower the billet price would increase the differential between billets and steel rails. Producers declare positively that these prices will not be disturbed, and that when the tariff legislation is ended conditions will immediately begin to improve.

As a result of the cut of \$5 per ton, or 25c. a box, in the price of tin andterne plates the American Sheet and Tin Plate Company is preparing to start a number of idle mills. It has been running 164 tin mills for several weeks, and on Monday will increase the active mills to 213, the highest number operated in two years.

In finished steel the Carnegie Steel Company has taken on considerably more business since the readjustment in prices, and its capacity is being increased. One of the two new blast furnaces which were added to the Duquesne group was blown in this week, and the other will be started in a short time. The company is now operating 35 of its 59 blast furnaces. Rail business is dull, and the three mills at the Edgar Thomson works are only being operated at about 40 per cent. of capacity.

Pig Iron—The market is practically dead, and unusually low prices are being named in order to induce buying. Some furnaces are quoting standard bessemer at \$14.75; malleable bessemer, basic and No. 2 foundry at \$14.50; gray forge at \$13.50, all at Valley furnaces. Other quotations are 25c. a ton higher, but there have been no sales of any consequence outside of one lot of 1000 tons off bessemer bought by the Westinghouse Air Brake Company at \$14.60, Valley.

Steel—Sales are light and prices unchanged as follows: Billets, \$23, Pittsburg; sheet-bars and tinbars, \$25.50; merchant-steel bars, 1.20c., and plates, 1.40 cents.

Sheets—Some new business is being placed at the ruling quotations, which are 2.30c. for black, and 3.30c. for galvanized sheets, No. 28 gage.

Ferro-manganese—Prices are much lower, \$41@41.50 being quoted.

Metal Market

New York, March 17—The metal markets continue in about the same condition as last week.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Feb. 1909..	\$ 8,860,814	\$ 3,576,413	Exp. \$5,284,401
" 1908..	1,967,597	2,847,131	Imp. 879,536
Year 1909..	16,726,170	6,996,596	Exp. 9,729,574
" 1908..	2,411,797	13,646,017	Imp. 11,234,820
Silver:			
Feb. 1909..	4,852,499	3,508,881	Exp. 1,343,668
" 1908..	4,108,774	3,461,755	" 657,019
Year 1909..	9,394,643	7,173,633	" 2,221,020
" 1908..	8,256,918	7,073,620	" 1,183,298

Exports from the port of New York, week ended March 13: Gold, \$3,823,050, chiefly to Argentina; silver, \$829,490, to London and Paris. Imports: Gold, \$608,250, from France, Central and South America; silver, \$89,037, from the West Indies and Mexico.

Foreign commerce of the United States, two months ended Feb. 28, reported by Bureau of Statistics, Department of Commerce and Labor:

Merchandise.	1908.	1909.
Exports.....	\$ 373,871,750	\$ 282,720,414
Imports.....	169,750,165	222,243,508
Excess, exports.....	\$ 204,121,585	\$ 60,476,906
Add excess of exports, silver.....		2,221,020
Add excess of exports, gold.....		9,729,574
Total export balance.....		\$ 72,427,500

The gold and silver movement in detail is given in the table at the head of this column.

The Treasury Department's estimate of the amount and kinds of money in the United States on March 1 is as follows:

In Treasury. In Circulation.		
Gold coin (inc. bullion in Treasury).....	\$ 186,394,881	\$ 609,988,369
Gold certificates.....	47,699,690	812,642,179
Silver dollars.....	6,878,913	72,158,899
Silver certificates.....	13,342,608	471,411,392
Subsidiary silver.....	24,895,000	130,767,140
Treasury notes of 1890.....	15,336	4,462,664
U. S. notes.....	10,922,510	335,758,506
Nat. bank notes.....	30,686,733	647,898,867
Total.....	\$320,795,671	\$3,084,778,006

Population of the United States March 1, 1909, estimated at 88,448,000; circulation per capita, \$34.88. The total circulation March 1 was 7,888,635 less than on March 1 of last year.

Gold and silver movement in France, year ended Dec. 31:

Imports.	Exports.	Excess.
Gold, Fr. 1,013,750,000 F. 23,379,000 Imp. Fr. 990,371,000		
1907..	444,431,000	154,573,000 Exp. 289,858,000
Silver..	174,099,000	175,893,000 Imp. 1,794,000
1907..	360,860,000	215,501,000 Imp. 145,359,000

Imports of copper and nickel coins, 109,000 fr. in 1907, and 73,000 fr. in 1908; exports, 703,000 fr. and 753,000 fr., respectively.

Gold and silver movement in Great Britain, month of January:

	Imports.	Exports.	Excess.
Gold, 1908.....	£ 3,228,260	£ 5,480,845	Exp. £2,252,585
Gold, 1908.....	3,225,392	2,938,590	Imp. 286,802
Silver, 1908.....	1,210,533	1,033,670	Imp. 176,863
Silver, 1908.....	569,555	1,436,570	Exp. 867,015

The excess of exports of gold and of imports of silver shown this year are both unusual conditions.

Gold—There has been no special demand for gold on the open market in London and prices remain at the mint value, 77s. 9d. per oz. for bars and 76s. 4d. per oz. for American eagles. The Bank of England has absorbed most of the supplies. In New York shipments have been made this week of \$2,400,000 to Argentina and \$3,500,000 to London; while it is reported that more will go on Saturday.

Platinum—Business has been a little better, but there are no signs of any change in price soon, though there is an impression that higher prices will come when demand improves. Dealers quote \$24 for refined platinum, \$26 per oz. for hard metal and \$19@21 for scrap.

Our special correspondent writes from St. Petersburg, under date of Feb. 18, that expectations of higher prices have not been realized, and large dealers now believe that there will be no change for some time. Crude platinum, 83 per cent. metal, is quoted at Ekaterinburg 5 rubles per zolotnik; in St. Petersburg, 20,000 rubles per pood. These prices are equivalent to \$18.80 and \$19.55 per oz., respectively. The annual conference of the Ural platinum miners, held at Ekaterinburg, Feb. 6-9, decided to petition the Government to make loans to miners at the rate of 16,000 rubles per pood of crude platinum.

Silver—The market has remained quite steady. The fluctuations have been slight, and the tendency is toward a movement within a small compass.

SILVER AND STERLING EXCHANGE.

Mar.	11	12	13	15	16	17
New York.....	50½	50½	50½	50½	50½	50½
London.....	23½	23½	23½	23½	23½	23½
Sterling Ex.....	4.8810	4.8810	4.8810	4.8815	4.8820	4.8820

New York quotations, cents per ounce troy, fine silver; London, pence per ounce sterling silver, 0.925 fine.

Exports of silver from London to the East, reported by Messrs. Pixley & Abell, year to March 4:

	1908.	1909.	Changes.
India.....	£ 1,490,538	£ 818,200	D. £ 682,338
China.....	496,400	200,000	D. 296,400
Straits.....	78,270	82,000	I. 4,530
Total.....	£ 1,975,208	£ 1,141,000	D. £ 834,208

Imports for the week, £3000 from Mexico and £2000 from New York; total, £203,000. Exports, £22,000 coin to the Straits and £6000 in bars to India; £28,000 in all.

Copper, Tin, Lead and Zinc

Mar.	Copper.			Tin.		Lead.		Zinc.	
	Lake, Cts. per lb.	Electrolytic, Cts. per lb.	London, £ per ton.	Cts. per lb.	New York, Cts. per lb.	St. Louis, Cts. per lb.	St. Louis, Cts. per lb.	St. Louis, Cts. per lb.	St. Louis, Cts. per lb.
11	12½ @13	12½ @12½	56	29	3.97½ @4.00	3.82½ @3.85	4.60 @4.62½		
12	12½ @13	12½ @12½	56½	29	3.97½ @4.00	3.82½ @3.85	4.60 @4.62½

15	12½ @12½	12½ @12½	54½	28½	3.97½ @4.00	3.82½ @3.85	4.60 @4.62½		
16	12½ @12½	12½ @12½	54½	28½	3.97½ @4.00	3.82½ @3.85	4.60 @4.62½		
17	12½ @12½	12½ @12½	55½	28½	3.97½ @4.00	3.82½ @3.85	4.60 @4.62½		

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, mainly New York, cash. The price of cathodes is usually, 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations for spelter are for ordinary Western brands; special brands command a premium.

Copper—The singular lack of interest which domestic consumers show in the present low level of prices has created considerable nervousness among selling interests. The selling pressure concentrated upon Europe, some business in electrolytic for export thither being done from day to day at receding prices, though the tonnage was relatively unimportant, owing to the fact that European buyers had well supplied themselves during the activity of about two weeks ago. Little or no business in Lake copper has been done, and quotations for that quality are nominal, the producers being in no way prominent in the market. The market closes barely steady at 12½@12¾c. for Lake copper; 12@12¾c. for electrolytic in ingots, cakes and wirebars. The average of the week for casting copper has been 12@12½c.

Copper sheets, cold-rolled, are quoted 17.3c. per lb., large lots; and hot-rolled, 16.5c. Copper wire, 14½c. base, carload lots at mill.

After holding fairly steady until the close Friday, the London standard market opened on Monday with a sharp decline, and on the second exchange on that date reached the lowest figures, £54 15s. for spot, £55 10s. for three months. Since then, under bear covering, there has been a recovery, the close being steady at £55 5s. for spot, £56 for three months.

Statistics for the first half of the current month show an increase in the visible supplies of 100 tons.

Refined and manufactured sorts we quote: English tough, £59 10s.; best selected, £58 10s.@£59 10s.; strong sheets, £70 10s.@£72 10s.

Copper exports from New York and Philadelphia for the week were 5538 long tons. Our special correspondent gives the exports from Baltimore for the week at 10-28 tons of copper.

European stocks on March 1 are reported as below, in long tons, by Henry R. Morton & Co., of London:

Visible stocks, Feb. 1.....	52,935
Supplies during February.....	24,653
Total.....	77,588
Deliveries in February.....	25,299
Stocks, March 1.....	24,290

Stocks include 38,242 tons in England; 6553 tons in France; 7700 tons afloat from Chile and Australia.

Tin—The bull party in London suddenly turned sellers, and prices consequently declined. The reasons for this change of front are not given, and it is hard to follow the tactics of these London speculators. The market closes steady at £129 for spot, £130 12s. 6d. for three months.

There is very little activity in the domestic market, the only remarkable feature being an over-supply of spot material which is pressed for sale. The quotations at the close are made at 28½ cts

Lead—The market has quieted down after some large transactions early in the week, but is holding well, as the recent activity has taken care of the cheap offerings and sellers can afford to be independent. The close is steady at 3.82½@3.85c. St. Louis, 3.97½@4c. New York.

The London market has been depressed throughout the week and the close is cabled at £13 5s. for Spanish lead, £13 7s. 6d. for English lead.

Spelter—Business has again fallen off to minimum proportions. On the one hand, consumers are well supplied, and, on the other, there is no pressure to sell. The close is steady at 4.60@4.62½c. St. Louis, 4.75@4.77½c. New York. The New York price was 4.75@4.77½c. throughout, March 11-17, inclusive.

The London market has again declined, and the close is cabled at £21 5s. for good ordinaries, £21 10s. for specials.

Base price of sheet zinc is now 6¼c. per lb., f.o.b. La Salle-Peru, Ill., less 8 per cent. discount.

The New Jersey Zinc Company announces that after March 22 its offices will be in the National City Bank building, 55 Wall street, New York.

Other Metals

Antimony—Business is extremely quiet. Prices nominally unchanged at 8@8½c. for Cookson's; 7¾c. for Hallett's; 7¾@7¾c. for ordinary brands.

Aluminum—Nothing new is reported. The Aluminum Company of America still quotes 24c. base for No. 1 ingots; 33@34c. base for sheets.

Quicksilver—New York quotations, \$45 @46 per flask of 75 lb. Business continues fair. San Francisco nominal at \$45 for domestic, and \$43 for export. London,

£8 7s. 6d. per flask, with £8 6s. 3d. named by jobbers.

Nickel—Large lots, contract business, 40¢@45¢. per lb. Retail, spot, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. The price for electrolytic is 5c. higher.

Cadmium—Current quotation 75c. per lb., in 100-lb. lots, at Cleveland, Ohio.

Magnesium—Quotations for this metal are \$1.25 per lb., New York, in 100-lb. lots; for 5-lb. lots, \$1.40 per pound.

German Metal Imports and Exports

Imports and exports of metals in Germany for the full year are reported as follows, in metric tons:

	Imports.	Exports.	Excess.
Copper, 1907.....	175,184	89,925	Imp. 105,259
Copper, 1907.....	144,002	62,511	Imp. 81,491
Tin.....	14,243	6,122	Imp. 8,121
Tin, 1907.....	13,020	5,848	Imp. 7,172
Lead.....	77,049	40,626	Imp. 37,423

Zinc ore.....	109,840	39,450	Imp. 169,290
Zinc ore, 1907.....	184,703	34,863	Imp. 149,840
Nickel ore.....	17,492		Imp. 17,492
Nickel ore, 1907.....	29,226		Imp. 29,226
Tungsten ore.....	2,308	133	Imp. 2,175
Tung. ore, '07.....	2,239	195	Imp. 2,044
Other ores.....	2,618	603	Imp. 2,015
Other, 1907.....	6,073	929	Imp. 5,144
Chrome ore.....	15,973	111	Imp. 16,084
Chrome, 1907.....	19,508	148	Imp. 19,360
Pyrites.....	334,133	16,884	Imp. 317,249
Pyrites, 1907.....	393,927	24,183	Imp. 369,744

Other ores include uranium, molybdenum and other minor metals, with some mixed or complex ores.

Zinc and Lead Ore Markets

Platteville, Wis., March 13—Prices continued the same as last week; \$37.50 per ton being the basis paid for 60-per cent. zinc. No premium was paid. For 80-per cent. lead ore, \$46 per ton was paid.

SHIPMENTS, WEEK ENDED MAR. 13

Camps.	Zinc ore, lb.	Lead ore, lb.	Sulphur ore, lb.
Hazel Green.....	343,300		281,050
Platteville.....	242,500	54,000	
Beaton.....	221,670

Total.....	1,494,050	54,000	281,050
Year to Mar. 13.....	21,865,239	710,180	1,980,650

In addition to the above there was shipped to the American Zinc Ore Separating Company 190,410 lb. zinc ore.

Joplin, Mo., March 13—The highest price reported for zinc sulphide ore was \$40 per ton, the base ranging from \$35.50 to \$38 per ton of 60 per cent. zinc. Zinc silicate sold at \$25 highest, on base of \$18@20 per ton of 40 per cent. zinc. Zinc, all grades, averaged \$34.24 per ton. Lead sold as high as \$50.50, the bulk of the ore selling around \$50 averaging, all grades, \$49.86 per ton.

The general decrease of the wage scale has made it possible for most of the mines to continue outputting on the present level of prices, even though the margin of profit is small; weather and general conditions are so favorable that the output continues to increase.

SHIPMENTS, WEEK ENDED MAR. 13

NOTE—Under zinc ore the first two columns give base prices for zinc ore and zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

Chemicals

New York, March 17—A fair amount of business is being transacted in small sales, although the market remains generally quiet.

Copper Sulphate—The market is quiet with no big sales reported. Prices held at \$4.60 per 100 lb. for carload lots and \$4.85 per 100 lb. for smaller parcels.

Arsenic—Sales for the week amount to about 200 tons at 27½c. per lb. The

market is not active and the price quoted is 3c. per lb. on white arsenic.

Nitrate of Soda—Quotations have been 2.15@2.17c. per lb. There has been some improvement in the market during the week.

Potassium Salts—Exports of potassium salts from Germany for the year are reported as below, in metric tons:

	1907.	1908.	Changes.
Kainit, kieserit, etc.....	839,889	818,589	D. 21,300
Potassium chloride.....	173,638	174,359	I. 721
Potassium sulphate.....	46,158	48,804	I. 2,646
Pot.-magnesium sulphate	128,344	182,943	I. 5,599

Exports to the United States in 1908, included in the above totals, were 364,731 tons kainit, kieserit, etc.; 100,587 tons potassium chloride; 25,957 tons potassium sulphate; 59,869 tons potassium-magnesium sulphate.

Petroleum Exports

Exports of mineral oils from the United States, two months ended Feb. 28, in gallons:

	1908.	1909.
Crude petroleum.....	14,899,445	17,832,045
Naphthas.....	3,829,138	6,410,792
Illuminating oils.....	161,995,537	152,036,316
Lubricating oils.....	26,123,918	20,609,612
Residuum.....	9,673,416	12,061,498
Total.....	216,521,454	208,850,263

Paraffin is included in lubricating oils. The total decrease this year was 6,671,191 gal., or 3.1 per cent.

Mining Stocks

New York, March 17—The general stock market has been distinctly narrow with some tendency to weakness. This tendency, however, has not been so marked as the unwillingness to trade much at present and the desire to await further developments especially in the industrial field. The special session of Congress began on Monday and the Exchange seems to be holding back until it can see what turn the tariff legislation will take.

On the Curb trading was not very heavy. The copper shares displayed considerable weakness, and buyers were not strongly disposed to take them up. Other stocks followed this lead and were inclined to be weak on moderate trading but without any heavy actual loss in prices.

The Curb was stirred up on Monday by an unusual out-pouring of "cats and dogs." There was a sale of 190,565 shares in all, made to close out an account. The prices were something startling to those brokers who have memories long enough to remember the quotations of a year or two ago. Among them were the following: Nevada Exploration, 60,000 shares at \$100 for the lot; Round Mountain Red Top, 35,000 shares at \$100 for the lot; Roanoke, 3950 shares at \$8 for the lot; Mohawk Extension, 17½c.; Gibraltar, 5½c.; Tramps Consolidated, 6c.; North Butte Extension,

4½c. Montgomery Shoshone held up best of all, bringing \$1.37½c. per share.

Boston, March 16—Notwithstanding the fact that there is little interest manifested in mining shares prices held wonderfully well. The annual reports of the various mining companies, now coming out from time to time, show lean treasuries. As a rule it is a surplus of liabilities.

Parrot has been a strong feature, advancing \$2.25 to \$32.12½, with fractional setback from this. Favorable developments in the lower levels are coming from the property. North Butte rose from \$67.50, ex-dividend, to \$68.50 and Calumet & Hecla is off \$15 to \$610. Osceola is off \$2 to \$128. The 1900 annual meeting resulted in a complete change in the directorate, Calumet & Hecla officials taking the places of the old board. The same people have issued the call for the annual meeting of the Isle Royale when a complete change in the management will take place.

Utah Consolidated directors have declared the usual 50c. quarterly dividend. Arcadian showed activity and a degree of strength. Reports have been current of Calumet & Hecla interests in this property but there is no foundation for them.

Nipissing and Ohio Copper were the Curb features.

On the Curb market hereafter there will be two departments, stocks being known as "qualified" and "unqualified," according to the degree in which they meet the requirements of the governing committee.

The Mount Morgan Gold and Copper Mine

Three Distinct Methods of Mining Are Employed, the Open Cut with Steam Shovel, the Milling System and Square-set Supported Stopes

BY GERARD W. WILLIAMS*

The Mount Morgan mine is situated 25 miles south-southwest of Rockhampton in Central Queensland. The mine itself is only a few miles south of the tropic of Capricorn. It was discovered in 1883 by Messrs. Morgan, who had been prospecting in the neighborhood. Since its discovery the mine has chlorinated 3,250,000 long tons¹ of ore for a return of approximately an ounce to the ton, while half a million tons have been smelted for a return of about 3 per cent. copper and 8 dwt. gold per ton. To July 10, 1908,

In the open cut the axes of the ellipse attain a maximum of 940 and 590 ft. The lowest level (950 ft. vertical) is opened up for more than 600 ft. in length and 250 ft. in width, but ore is still in the face and both width and breadth will be considerably exceeded.

The orebody is traversed by numerous dikes, of which four are extremely well defined. The north and south dikes run parallel, about 450 ft. apart and strike northwest-southeast. These dikes are almost vertical and average 20 ft. in width.

copper ore, now estimated at more than 3,000,000 tons, lies to the west of the andesite dike. The dike itself averages 20 ft. in width and is almost vertical. It runs across the open cut and standing out from the softer ore it forms a conspicuous feature.

NATURE OF THE OREBODY

There is practically no contact enrichment at the dike faces, which show slickensides in some places in the dike matter itself, but give no evidences of

OPEN CUTS AND DUMP, LOOKING SOUTH. CONTOUR OF ORIGINAL HILL SHOWN BY DOTTED LINE

the total value of gold and copper produced amounted to slightly more than \$70,000,000, of which \$37,000,000 has been paid in dividends. The nominal capital of the company is £1,000,000.

The surrounding country is composed of highly altered sedimentary rocks traversed by a large series of dikes of varying geological age. The orebody in outline resembles an irregular ellipse, the longer axis running northwest-southeast.

The south dike is still in the ore in the bottom level, but the north dike leaves the lode and passes into the country at 650 ft. The east dike is a branch of the south dike and runs in a general north-east direction.

The biggest dike is known from the nature of the rock as the andesite dike. This dike runs north and south and crosses the south dike above the 750-ft. level. This dike was formerly considered the limit of payable ore, and it is only since diamond-drill work was started that the country beyond the dikes has been opened up. Practically the whole of the

having faulted the orebody. The dike material has been considerably altered, the smaller dikes being completely kaolinized; even at the lowest level the surface of the larger dike shows signs of alteration. When one considers that the unoxidized ore averages 25 per cent. pyrites, and that more than 2,000,000 tons of leached ores have been excavated from the open cut the quantity of acid produced by oxidation must have been enormous. It is not surprising, therefore, that all the rocks have been highly altered. The nature of the unoxidized ore varies widely from ultra basic (10 per cent.

*Consulting engineer, Melbourne, Australia.

¹Throughout this article all tons are of 2240 lb. The short ton is not used in Australia, except in West Australia.

silica) to ore containing 80 per cent. silica. Generally speaking, the highly mineralized basic ores are high in copper and low in gold, while the silicious portions of the orebody are rich in gold, but low in copper. The whole of the un-oxidized ore may be averaged at 65 per cent. silica and 3 per cent. copper, the balance being chiefly iron pyrites.

Several theories as to the genesis of this orebody have been put forward. The oldest and best known theory was advanced by Dr. Logan Jack, that the deposit was due to a vast geyser. This theory has been completely abandoned, the silicious sinter which was supposed to occur in the open cut having been shown to be really a stockwork of small veins of infiltrated silica. In the light of recent work at depth it would seem that the ore was deposited from ascending mineral-

mine he is fully qualified to express an opinion. While adopting the theory of upward percolation through a crush zone he finds it impossible to account for the sharp demarkation between lode and country rock.

The gold contents show a natural decrease from the outcrop downward, but in the copper mine the value appears to be fairly uniform. All the copper occurs as chalcopyrite; there are no carbonate ores. Black sulphides occur but rarely and then as impregnations in felsite dikes.

METHODS OF MINING

The mining methods may be divided into three classes: Open cut in the oxidized ore for supplying oxidized ore for the west chlorination works, the "mundic" stopes, which send ore to the mundic works for roasting and chlorination and

present management decided that the bulk of the ore would pay to remove for treatment and the present open cut was started. Working down on benches the steam shovels remove the old stope fillings, dike matter and overburden and load it upon electric trams which carry it out through adits in the hill side and tip it into the valley at the side of the mine, or to winzes leading to the stopes below. Two steam shovels are in constant use, a small one having a capacity of 450 tons per shift which is used for opening up new benches and a larger one which follows in the wake of the small one and removes from 800 to 1200 tons per shift.

At the time the estimate was made the ratio of overburden to ore was placed at 4 to 1, but this ratio has been slightly reduced owing to the fact that in many cases the old stope fillings paid for treat-

CROSS-SECTION, COPPER MINE

The Engineering & Mining Journal, N. Y.

bearing solutions which permeated a zone of crushed or weakened sedimentary rocks. These rocks were completely altered in their composition and in addition to the deposition of sulphide of iron considerable infiltration of secondary quartz took place.

It is noteworthy that the lode does not shade off into the country rock, but that the line of demarkation of the elliptical orebody and the surrounding rocks is well marked. It is certainly somewhat difficult to account for a crush zone of this shape, and this is the strongest argument against this theory. J. Bowie Wilson, late mine manager at Mount Morgan, recently published several valuable papers¹ dealing with the genesis of this deposit, and from his long association with the

the copper mine. The oxidized ore extends to a depth of about 400 ft. below the old hill top; the mundic stopes follow down 500 ft. vertically and then appear the newly opened stopes of the copper mine, which have been opened up down to 950 ft. The whole orebody is continuous and the above divisions are purely arbitrary, for silicious ore low in copper and high in gold occurs in the copper stopes and basic ore low in gold and high in copper has been won from the mundic stopes.

The open cut covers an area of 11.2 acres and measures 1030 ft. and 710 ft. in greatest width and breadth; of this 910 ft. by 500 ft. represents ore.

In the old days the rich gold ore, which occurred in very irregular shoots in the mass of the orebody, was stope out with square setting from adit levels driven from the hill side. A few years ago the

ment. The cost of removing overburden and waste varies from 10 to 15c. per ton. The bulk of the overburden has been removed and for the last 12 months the ratio of overburden to ore was only 1 to 1.8.

The ore is won by benching and by "milling." In the former method the faces of ore left by the steam shovels are broken down by deep, vertical "jumper" holes and the broken ore is shoveled into ore passes leading to the 450-ft. level below, or is removed by the small steam shovel.

MILLING SYSTEM

The milling system was borrowed, I think, from America. It certainly merits a few words of description for it is not so well known as it should be. A level is driven into the face of the ore from the floor of the cut and from the end of the

¹ *Aust. Mining Standard*, Aug. 12, 1908, et seq.

level a rise is put up to the surface. The rise is fitted up as an ore chute and rails are laid into the level. Starting at the surface opening of the rise the ore is broken into it from all sides. The miners work back from the opening of the ore pass in such manner that the sides of the conical "rill" are steep enough to allow all broken ore to fall down to the ore pass in the center.

Viewed from the crest of the big andesite dike which crosses the open cut the

chine men \$2.24 to \$2.40 per eight-hour shift. The floor of the open cut is now 340 ft. below the crest of the old hill. The dotted line in the accompanying illustration shows the former contour of the hill.

THE MUNDIC MINE

The stopes in this portion of the orebody are worked by the square-set method. The sets measure 6x5 ft. between centers on the sill and 7 ft. 9 in. in height. The

swinging sets the price for breaking ore and erecting sets varies from \$16.20 to \$22.40 per set, and for sill floor sets from \$30 to \$42. A set averages 23 tons of ore.

The total costs average \$2.97 per ton, and development 50c. per ton mined.

THE COPPER MINE

The copper stopes are all to the west of the big andesite dike, which for many years was considered to be the eastern limit of the payable orebody. Six

PLAN OF COPPER MINE

The Engineering & Mining Journal, N. Y.

LONGITUDINAL SECTION, COPPER MINE

The Engineering & Mining Journal, N. Y.

"mills" appear like so many gigantic antlions' pits. Some of these mills measure 200 ft. across; but their size naturally varies within wide limits as adjoining mills encroach on each others' territory.

COMPARISON OF COSTS OF MINING, PERIOD OF SIX MONTHS.

BENCHING SYSTEM.	
Ore and waste (65,103 tons)	49c.
Ore charged with waste (32,962 tons)	82c.
MILLING SYSTEM.	
Ore and waste (71,632 tons)	26c.
Ore charged with waste (32,962 tons)	43c.

All labor in the open cut is by day's pay. Miners earn from \$2 to \$2.24, and ma-

timber is all square-cut 9x9 in., and is joggled in the usual manner except that the struts are given a 1-in. shoulder instead of carrying the full-sized tenon. The wood used is known as spotted gum and is obtained locally. It is stronger than Oregon pine and stands well. It does not, however, "talk" when taking weight, but is liable to snap suddenly. The timber costs \$3.40 board measure and is cut from the logs in the company's mills. Per ton of ore the cost of timber averages 44 cents.

The ore is mined by contract, the contract price being based on the number of square sets and not on footage nor tonnage. On

years ago diamond drilling was started and large masses of copper ore were located. For three years systematic exploratory work was carried out and at the end of that time 3,000,000 tons of 3.5-per cent. ore had been located. This drill work cost \$150,000. As soon as the ore was proved a smelting plant was erected at a cost of more than \$1,000,000 and was paid for out of the profits on one year's work. Without calling up a cent of capital and without interfering with the production of gold the Mount Morgan mine commenced a new existence as a copper-smelting enterprise. Typical secondary

ores were entirely absent from the upper levels and the portion of the orebody which contains the copper ore was previously regarded as valueless.

The mine is opened up with levels at 450 (the mundic level) 574, 650, 750, 850 and 950 ft. vertical depth. Only the 750- and 850-ft. levels in the copper mine are at present being stoped. The main underlay shaft is down 1035 ft. vertically.

The orebody, which may be taken as 650 ft. in length and anything above 260 ft. in width is opened up by means of drives parallel with the longer axis of the orebody and 60 ft. apart. Large crosscuts run at right angles to the main drives. This method of development blocks the ore out into panels or chambers 60 ft.

Along the sides of the chamber a continuous line of solidly built pigsties is erected which form the sides of the drives and crosscuts and ultimately convert the whole chamber itself into a gigantic waste-filled pigsty. Waste is sent down from the open cut and distributed by winzes to the chambers. Ore passes are placed in the level every alternate 15 ft. Once the sill sets are in and the waste spread and leveled out, another face is taken off the stope and the filling repeated. Meantime the adjoining chambers are working up, each inclosed in its wall of pigsties.

The accompanying plans, supplied by the management for the purpose of illustrating this article, explain the whole system very clearly. It will be noticed that all drive

thousand tons and crushed down the bulkheads until it rested on the waste beneath.

The government is at present holding an inquiry into the causes of the accident, and will doubtless recommend some other form of stoping practice. Probably the use of a larger number of bulkheads in the working faces, each bulk being filled up with broken rock, will enable the present method to be continued. The frequency or otherwise of serious accidents is not always a fair criterion of safe working, for there is at times something of "cussedness" in inanimate matter that defies all laws, and it is not improbable that were the present method continued no more accidents would occur.

TIMBERING METHODS IN STOPES OF COPPER MINE

wide and usually 250 ft. to 300 ft. in length. The ground plan of the sill floor thus determined, stoping commences in one or other of the center chambers.

METHOD OF WORKING

The ore being vertical there is no need to begin from the footwall side. The sill floor is cut out and the leading stope carried to a height of 14 ft. above the floor of the sill. Bulks of timber, composed of old square-set timbers recovered from the old stopes laid bare in the open cut, are used to support any heavy ground in the roof. The sill floor is laid with logs of brigralow, a cheap timber which occurs locally and which stands well underground. The bed logs are floored with 4-in. planks of Colonial pine.

timbering is done away with and the expensive sawed timber sets are replaced by a wall of round logs slightly joggled into each other.

In every way the method appears to be extremely safe; not only does the panel system eliminate the possibility of "creeps" caused by the crushing of wide spans of ore as the stope works up to the level above, but by the use of bulkheads the danger of small falls of rock is lessened or entirely done away with. At the time of my visit a few months ago 300,000 tons of ore had been excavated without a single accident; then, without warning, came three disastrous falls, two of which were attended by serious loss of life. The ore, although apparently absolutely solid gave way in masses weighing several

LABOR AND WAGES

All miners, except those employed in the open cut are contract workers. In the copper mine the men work in gangs of 16 to 24. Usually the gang or party rig up and bore out a face right across the chamber; the face is then fired and while one machine is employed squaring off the face the rest of the party spill up the ore and deliver it to the ore passes.

The ore is taken to the plat by an electric tram and every truck is weighed as it passes to the plat. The contract men are paid on the actual weight of ore sent up. The price paid varies from 60c. to \$1 per ton, the higher rate being paid in the sill-floor stopes.

Mining costs in the copper mine are abnormally high at present; out of six work-

ing stopes four are on the sill floor and the cost of flooring boards, etc., runs the costs up. Dike material represents 13 per cent. of the total ore broken. This is sorted in the chambers; at one time it was sorted on a belt at the surface but the cost was too high. The main underlay shaft carries two skip ways; each skip carries from seven to ten tons according to the nature of the ore. The trucks from the levels are tipped into bins in the floor of the level which discharge through chutes to the skips.

Mining costs for the six months ending May 31, 1908, averaged \$2.28 per ton. The ore reserves of the copper mine (down to the 850-ft. level) are estimated at 1,280,000 tons containing 3.5 per cent. copper and 8 dwt. gold and 1,700,000 tons containing 3 per cent. copper and 2.5 dwt. gold. This does not include ore in the mundic stopes or in the open cut. The former is estimated to be equal to ten years' supply for the mundic plant, approximately a million tons.

Short Talks on Mining Law—XIV

By A. H. RICKETTS*

The use of water on the public domain was primarily regulated by miners' rules, regulations and customs. The vested and accrued rights in water, recognized and given by local legislation and the decisions of the courts, received early recognition and sanction from Congress. The appropriation and use of water are now regulated by local statutes, which vary in detail, and the rights of the appropriator depend upon his compliance with these local laws. Grants of the public lands are made subject to all water rights that may have previously accrued to any person other than the patentee. In forest reserves rights of way for the construction and maintenance of dams, reservoirs, water plants, ditches, flumes, pipes, tunnels and canals within and across the forest reserves of the United States are granted by congress for mining purposes and for the reduction and milling of ores during the period of their beneficial use under such rules and regulations as may be prescribed by the secretary of agriculture, and also subject to local statutes. Congress has also provided for rights of way through the public lands, forest and other reservations of the United States, and through the Yosemite, Sequoia, and General Grant national parks, of California, for canals, ditches, pipes and pipe lines, flumes, tunnels, or other water conduits, and for water plants, dams and reservoirs used to promote mining or quarrying or the cutting of timber. Lands valuable for mineral deposits and embraced within a withdrawal of lands susceptible of irrigation by means of a reclamation project under the Act of June

17, 1902, are not taken out of the operation of the mining act, but continue open to exploration and purchase under such law.

WATER RIGHTS

All surplus water over and above that necessarily used for the purposes of irrigation and reclamation of desert land, part of the public domain, together with the water of all lakes, rivers and other sources of water supply upon the public lands and not navigable may be appropriated for mining purposes when not violative of the reasonable rights of others. But the right to appropriate water is not confined to streams running over public lands of the United States, but exists whenever the appropriator can find water which has not been appropriated or in which no other person has or claims superior rights and interests and by the latter only as far as there is a conflict.

The size of the stream is immaterial. It may run upon or beneath the surface of the land (but it must be separate and distinct from the soil whether produced by percolation, filtration or otherwise), flow in a river or down a cañon or ravine, or it may consist of percolating waters collected or gathered in a stream running in a defined channel or of water flowing from a well, whether flowing away or standing in a pool or a small lake, or flowing from springs or developed in a tunnel and conducted away, by owners of adjoining lands, from land where the waters would otherwise in their natural course sink into the ground and be lost. A person who enters upon the public lands and digs a well has a superior title to the use of the waters from the well. Until the performance of the conditions upon which the right to forever maintain possession is based, the person taking possession has no title legal or equitable as against the Government.

TIDE LANDS

Lands "under tide water" or "below high-water mark," "lands flowed by the tide" and other expressions of like import are usually employed in defining tide lands. The term "shore line" has been construed to mean high-water line. Lands under tide water are vested in the United States and are not subject to exploration, occupation or location under the mining act, except that in Alaska temporary possession thereof may be had for mining purposes subject to such general limits as may be necessary to exempt navigation from artificial obstruction. So, a mill-site location cannot lawfully be made in Alaska within 60 ft. of the "shore line" of navigable streams, etc.

The term "miner's inch" is not definite without specification of the head or pressure. In California the standard miner's inch of water is equivalent to $1\frac{1}{2}$ cu. ft. of water per minute measured through any aperture or orifice.

TIMBER CUTTING

Timber on mineral lands may be felled and removed by citizens and *bona fide* residents (but not by railroad corporations) of Arizona, Colorado, North and South Dakota, Idaho, Montana, New Mexico, Nevada, Utah, Wyoming and all other mineral districts of the United States for mining, smelting, roasting of ores or other domestic purposes.

Land chiefly valuable for timber may be acquired under the provisions of the "timber and Stone act." Where the character of land sought to be acquired under that act is put in issue, entry will be allowed by the Land department only when it appears that the growth of timber thereon is so extensive and so dense as to render the tract as a whole, in its present state, substantially unfit for cultivation, and that the land is chiefly valuable for the timber thereon.

Miners and prospectors have the free use of timber and stone within a forest reserve for mining, prospecting and other domestic purposes under such rules and regulations as may be prescribed by the Government. The secretary of agriculture may permit the exportation of timber cut or removed from the forest reserves of the United States or the district of Alaska, except the Black Hill forest reserve in South Dakota and the forest reserves in Idaho.

A valuable growth of timber upon land located as a placer claim may properly be an incentive to its location; the validity of this location will be upheld if otherwise unobjectionable. So, if any land is in fact mineral in character, title to the land, together with the timber thereon may be acquired under the mining act and, if vacant and non-mineral and chiefly valuable for timber, but unfit for cultivation and containing no mining or other improvements, it may be purchased under the provisions of the "Timber and Stone act."

The Victorian government's antidote for cyanide poisoning is put up in the form of a package containing the following: A hermetically sealed bottle containing $7\frac{1}{2}$ grams ferrous sulphate dissolved in 30 c.c. water; a bottle containing $1\frac{1}{2}$ grams caustic soda, dissolved in 300 c.c. water; and a tube containing 3 grams of magnesia. The ingredients are to be mixed and introduced into the patient's stomach through a rubber tube which acts as a siphon for emptying the stomach of its poison. The package is to be hung in some easily accessible place in the mill.

Mine timbers placed near decaying wood, according to a bulletin of the U. S. Forest Service, decay much more rapidly than if they are isolated, infection being communicated from the diseased to the new timber.

Tonnage Estimation in Dumps, Open Cuts, Etc.

The Density Factors for Solid and Broken Ore, Tailings and Slime Are Discussed, and Different Methods of Measuring Tonnages Described

BY R. J. DONALDSON*

In estimating the weight of material in any orebody, bin, or heap, the volume is first found, and then divided by a density factor, generally the number of cubic feet per ton. I will deal with the determination of this factor first, and for shortness will refer to it simply as the factor for the material under notice.

DENSITY FACTOR

This determination is really the most difficult and unsatisfactory operation in the estimation of tonnages. The value of the factor may vary largely for any material according to conditions in themselves impossible to determine. For instance, take rough, crushed ore in a bin. A mixture of sizes is heavier, bulk for bulk, than any one size alone, so that the factor for the crushed ore will vary with the proportion of coarse to fine. The factor used will nearly always be so many cubic feet per ton dry weight, but the moisture content may make a big difference in the packing of the ore, and, of course, differences in the assay value and in the constituents of the gangue will affect the figure.

These variations in the factor may be so great as to render an estimate little better than a guess. The concentrates from the various flotation processes are particularly liable to vary, and I have known one case in which the factor ranged from 15 up to 30 cu.ft. per ton.

RELATIONS OF THE FACTOR FOR SOLID TO THAT OF BROKEN ORE

In the appendix to "Ore Dressing," by Prof. R. H. Richards, the following authorities are quoted: Vezin, for "fairly finely crushed" ore, makes the factor for broken ore 1.75 times that for solid; Kirby, for run-of-mine ore, broken, 1.53 to 2 times the solid; McDonald, probably for run-of-mine ore, factor for broken 1.74 to 1.85 that for solid ore.

Examples of Broken Hill practice are 1.6 to 1.73 times the solid factor. Trautwine states that 1 cu.yd. solid breaks to from 1.75 to 1.9 cu.yd. in ordinary excavating. He also gives figures for three sizes of clean quartz sand. The coarsest contains 41 per cent. voids, the finest 50 per cent., i.e., the factors are 1.7 and 2 times the solid factor respectively. This is for loose sand. The medium sand gives intermediate values.

These figures for sand, taken by themselves, seem to confirm the often printed statement that the finer the crushing the bigger the percentage of voids, and, therefore, the higher the factor. But compare the coarse-sand factor with that given by the same authority for rough, broken material, and the two are found to be the same. Again, the coarse sand well shaken and jarred has a factor of only 1.47 times that for solid, and so is then heavier than rough, broken material.

In this connection the following table of factors (cubic feet per long ton) for different sizes of anthracite, given by C. Enzian, in a paper in the *ENGINEERING AND MINING JOURNAL* for July 27, 1907, is interesting:

CUBIC FEET OF ANTHRACITE PER LONG TON

Buckw't, Pea, Nut, Stove Egg, Broken.
41.4 42.1 38.4 38.5 38.8 39.4 * Lenig.
40.4 41.1 39.4 39.5 40.0 40.1 Wyoming.

It appears that the factor drops, i.e., the material gets heavier as the size diminishes from "broken" to "nut," jumps to a higher value than ever at "pea" size, and then falls again at "buckwheat."

The truth seems to be that the finer the crushing the lighter, bulk for bulk, the material may be, but at the same time it becomes more compressible, and the factor is affected to a much greater extent by the conditions of deposition.

The following experiments on the factor for Broken Hill mill slimes show how greatly it, a very fine material, varies in weight according to these conditions. The experiments were carefully conducted in a strong tin holding about $\frac{3}{4}$ cu.ft., the volume being found by weighing it empty and then full of water.

The values for tailings show that they are less sensitive to conditions of deposition, but still vary greatly.

By measuring a dump of tailings before and after a known weight—some hundreds of tons—had been removed, a factor of about 18 was obtained.

Unfortunately there is no connection between the two sets of figures, and a set of careful experiments seems to be needed on the density of the same material in different sizes. I have come across very little literature on the subject.

THE ACTUAL DETERMINATION OF FACTORS

In estimating the tonnage in any underground orebody, it is necessary to know the number of cubic feet of solid ore required to weigh a ton. The determination

DENSITY FACTOR FOR SLIME UNDER DIFFERENT CONDITIONS.

	Cu.Ft. per Ton (dry).
Dry slime, lightly shaken	25.8
Slime with 2 per cent. water, well rammed	19.6
Slime with 4 per cent. water, well rammed	18.4
Paste, 23 per cent. water	22.0
Same paste, dried in sun to 6.5 per cent. water	18.0
Weighting the slime dug from a hole in a dump 2-ft. cube gave a factor on the average of.	19.0

DENSITY FACTOR FOR TAILINGS UNDER DIFFERENT CONDITIONS.

	Cu.Ft. per Ton (dry).
Loose, dry.	20.32
Dry, well rammed	17.08
Dry, well rammed (repetition)	16.83
2 per cent. water, well rammed	18.04
15.5 per cent. water, well rammed	18.08

of the specific gravity of specimens will give an approximate figure, but an allowance, say, 5 or 10 per cent., or even more, will almost always be necessary for vugs, etc. In the case of lodé material which varies in density, the specific gravity of typical specimens of the different classes of ore should be found, and an attempt made to average the figures obtained, according to some estimate of the relative quantities of the different classes.

Much the best way, however, in an established mine with reliable records, is to measure the volume of the depleted stopes on any one level, from the cross-section, in the same way as the reserves would be measured or the volume might be calculated from the floor plans. From this volume and the recorded extraction from the level, the factor is easily obtained. It is generally possible to find a recently opened level with a reliable record of extraction. The factor got in this way is, of course, exactly the figure required, being the number of cubic feet as represented on the cross-sections or floor plans necessary to be mined to produce one ton of ore. It should agree approximately with the theoretical factor; otherwise there is likely to be some serious error in the method used for finding the volume.

FACTOR FOR ROUGH BROKEN ORE

Estimating the factor for rough broken ore is difficult. Having found the factor for ore in place, it may be multiplied by one of the figures given by Trautwine and other authorities to get the factor for broken ore. Sometimes an opportunity occurs for measuring a bin before and after a known weight of ore has been put into it. Or a railway truck full may be very carefully measured up and weighed.

FACTOR FOR TAILINGS AND CONCENTRATES

As mentioned before, the conditions of

*Broken Hill, New South Wales, Australia.
NOTE.—Abstract of paper read before the Scientific Society of Broken Hill, and published in *Aust. Min. and Eng. Review*, Dec. 5, 1908.

deposition affect the figure for these fine materials so much that the determination is very difficult and unsatisfactory. In the case of concentrates it is generally possible to get a figure by shipping and weighing the whole of a heap (or contents of a bin) previously carefully measured. In the case of tailings and slimes, it is not often that this can be arranged, and we have to fall back on weighing a known and necessarily small volume. The figures already given show how unreliable the data obtained in this way may be. It is obvious that, under these conditions, it is absurd to waste time on a fine determination of volume when an error of 5 per cent. or more may unavoidably occur in the density factor. It is also obvious that an estimate can only be after all an estimate, and not an exact measurement.

MEASUREMENT OF VOLUMES UNDERGROUND

The chief problem is the estimating of ore reserves. In a lode of uniform width, the area of proved but unstopped ore as shown on a projected longitudinal section should be taken and multiplied by the width measured normal to the section. Sometimes a simple arithmetical calculation is all that is necessary. In a wide, irregular lode, such as the Broken Hill lode, there are two chief methods. The first is to multiply the mean of the proved ore areas (whether stoped or not) on two adjacent levels by the distance between them, and afterward to subtract the recorded extraction between these levels. As the mean-area method gives a value too high when the end areas differ much, in such a case it would be better to use the prismoidal formula. The middle area would be got by plotting a plan half-way between the levels, by the aid of the sections and floor plans. The second method is much better. It is, however, necessary to have accurate cross-sections of the lode at frequent intervals, the frequency, of course, depending on the irregularity of the orebody. In Broken Hill practice the sections are spaced at intervals varying from 20 to 50 ft. The mean of the areas of proved unstopped ore on any two sections is multiplied by the distance between these sections. This method is more laborious, but much more exact, as it takes into account bulges, etc., between the levels. It has two other great advantages. No reliance is placed on records of extraction, which are often very unreliable indeed, especially in the older levels; and the tonnages are obtained separately for each section of each level—a very important point, as it is often desirable to know the approximate tonnage to be won by carrying out some particular piece of repair or development work.

An estimate of ore reserves might, of course, be made by finding the area of ore left unmined on each floor plan, but the conjectured wall would generally have to be drawn in on the cross-sections,

and transferred to the floor plans; moreover, the tonnage in each separate floor of a level would be a figure of no practical value.

UNDERGROUND EXCAVATIONS

In Australia these are generally measured in cubic fathoms. In the case of measuring up fathoms for stoping contracts in a narrow lode of fairly uniform width, the stoping may be plotted on a projected longitudinal section, and the measured widths (normal to the section, not necessarily to the lode) figured on in their correct positions. By narrow lode, I mean one in which the whole lode from wall to wall is taken out in one stop. The area of stoping on the longitudinal section is then multiplied by an average of the widths over that particular area. Care should be taken in averaging the widths over any area to give each measurement its proper value. For instance, suppose we have a square with widths as shown, the mean width is not the sum of the widths divided by nine, but is obtained thus:

2x1	—	2
3x2		6
5x1		5
3x2		6
5x4		20
7x2		14
2x1		2
4x2		8
8x1		8
———		1671
		4.43

If the widths of the small squares are averaged separately, and the mean width of the four averaged again, the corner widths will be used only once, the side widths twice, and the center width four times.

This is a very simple example. In an irregular area judgment must be used in valuing the measurements. In irregular underground excavations, cross-sections at intervals depending on the change of form of section must be used. These cross-sections would be taken with the level and staff, the staffman measuring the height to the back, and calling it to the instrument man at each level point. With much of this work to do it would pay to have a special column marked, "heights to back," in the level book.

MEASUREMENT OF CONTENTS OF BINS

In irregular box-like bins, never surcharged, the simplest method is to take a number of measurements at regular intervals from the top down to the surface of the material, and then average these depths (according to the method of averaging mentioned before). Knowing the whole depth of the bins, we can then get the average depth of ore. In bins with hopped bottoms of various shapes, the same general method may be followed, if the capacity of the bin for each foot in depth is first calculated. Surcharged bins

or bins in which the surface of the material or the bin bottom is very irregular, are best measured by plotting cross-sections, and taking out the areas in the usual way. Where bins of irregular, empty section have to be measured, it pays to have the sections of the empty bin plotted to scale in ink in a notebook of handmade paper. The surface of the contents of the bin may often then be simply sketched on the section in pencil, and rubbed out before the next measurement. Having the empty section already drawn saves a lot of time in the field.

MEASUREMENT OF DUMPS

To estimate the contents of a dump of pile of ore is frequently necessary. If the dump is of great area, and there are no records of the original surface levels, the estimate can only be approximate. In the case of large, flat-topped tailings dumps, in which the top area is not very different from the bottom area, and on fairly level ground, or ground of small uniform slope, an estimate may be made from a plan showing the edge and the toe. A series of levels should be taken around the toe, and another series to the same datum at intervals on top. The top of such a dump is generally fairly level, so that no particular care is needed in spacing the levels. The dump may then conveniently be divided into sections or divisions, the area of the top and of the bottom of each division taken, and the mean reduced level of the top and of the bottom found separately by averaging. By simply taking the mean of the top and bottom areas, and multiplying by the difference of the mean levels, we get an approximation, but for closer work the prismoidal formula should be used. Since the batter of a dump is usually uniform at any one place, even if part of the dump has been removed, the middle area may easily be found by drawing a line around the dump half way between the edge and the toe. If the dump lies on steep or irregular ground, the calculation should be made from cross-sections, taken at right angles to the top center line. The right angles may be laid out by optical square or pocket transit. The center line, of course, should be approximately the greatest length of the dump. As long as the cross-section keeps about the same value, 40- or 50-ft. intervals along this line on a big dump, together with the use of the mean area method, will be sufficient. At the ends the sections must be closer, and the prismoidal formula should be used. In settling this important question of the spacing of sections in any estimate, it must be constantly remembered that the prismoidal formula is mathematically correct, and the mean area method an approximation, for any solid with parallel ends, and capable of being generated by a right line moving on the boundaries of the end areas—in other words, for any prismoid.

MEASUREMENT OF LONG HEAPS

In measuring long-shaped heaps of small section, such as heaps of coal or concentrates piled along railway lines for subsequent reloading, it is, however, impossible without the use of a multitude of sections to adhere closely to this rule. The sections can with practice be so placed at fairly long intervals—say, 30 or 40 ft.—that the material lying between them could be shoveled up into an approximate prismoid. In dumps of this sort, a close estimate can, of course, be made mechanically by spacing the sections at regular short intervals—5 or 10 ft., according to the regularity of the heap. This way, again, would mean a multitude of sections to take, plot and calculate, but this method must be followed for periodical measurements, if the area under the dump is very irregular. Bottom sections should be taken before the dump is formed, at, say, 10-ft. intervals, and plotted in ink, the sections of the dump itself being taken at the same points, and plotted in pencil on the bottom sections. When called upon to measure a dump on irregular ground, with no previous levels on record, a vivid imagination is exceedingly useful. A party of three men can very quickly estimate these long dumps—3000 or 4000 tons spread over $\frac{1}{4}$ mile of railway can be measured up in about four hours as far as the field work is concerned. A good system is this: The leader pegs out half a dozen sections, at the greatest intervals at which he can mentally shape all the material between them in prismoids, with the pegged sections as end areas. He then records the sections distances and offsets as they are taped and called out by the other two men, then leaves them to get the levels (with a dumpy, which is much quicker than any pocket level), and proceeds to peg out sections on another length of dump until the first lot of levels is completed. Where much of this work has to be done, it pays to have special books or sheets printed for recording field notes, thus:

Section.	Staff Reading.	Offset.	Remarks.

A complete set of notes can then be taken on one page of a book, or on half a sheet where the loose-leaf system of recording field notes is used. Each section is complete in itself, as where stuff has to be shoveled out of trucks and in again it will never be piled so high that all the levels cannot be taken off one set up. There is, therefore, no need to reduce the levels, but the section can be plotted direct off the line of sight of the instrument as datum line.

MEASUREMENT OF IRREGULAR CONES

In calculating the tonnage in irregular

cones the best method is to make a contour map of it. A rough theodolite traverse should be run around the toe, and from each station bearings, vertical angles and slope distances taken to any changes of slope in the sides and to one point on top. Then find the reduced levels of the station points around the base, make a rough survey of the top off the point fixed by slope from the bottom survey, and take levels over the top reduced to this point as datum. Now plot the whole survey in plan, and figure on the reduced levels, calculated to the one datum, at all the points fixed. Contours at any desirable intervals may then be plotted by interpolation. The areas of the contours may then be taken out, and the volume calculated by either the mean area or the prismoidal formulas. In taking out all these irregular areas, a planimeter is almost a necessity, although tracing linen or paper ruled into small squares will do as a makeshift. A planimeter should be occasionally tested on a carefully plotted square of known size. Even on small areas of 1 or 2 sq.in. area, the planimeter will give results within about 1 or 2 per cent. Where sections are to be used only once, it pays to plot with a hard pencil, grooving the lines well in so as to facilitate guiding the point of the planimeter. Of course, where the top section is plotted on a permanent bottom section, and rubbed out so that the latter can be used again, a soft pencil is necessary.

MEASUREMENTS OF EXCAVATIONS, SUCH AS QUARRIES AND OPEN CUTS

This is a branch of work in which I have had very little experience. The same general methods of plotting cross-sections and calculating the volume from their area would be followed, but the difficulty would lie in taking the sections across steep and irregular falls. I have raised the point in the hope of discussion.

In discussing the above paper, C. W. Matters suggested a useful method for measurements of open cuts. A center line is first pegged along the bottom of the quarry. A theodolite is then set upon the section points (at suitable intervals), and a right angle turned and the section marked out. For the bottom of the open cut the theodolite is used as a dumpy level, and offset distances and levels taken as usual. For the irregular sides vertical angles are taken, and slope distances to the points measured with a steel tape. The chainman takes a level staff with him. Where possible the angle and slope distance is read direct to the point on the side, but where hummocks of rock, etc., intervene to hide the actual point, the staff is held vertically on it, and the angle and slope distance read to a figure on the staff, which is recorded in a separate column.

H. Warlowe Davies considered that Mr. Matters' method would be slow, as leveling with a theodolite is not so quick as

with a dumpy, and an optical square would be much quicker and quite accurate enough for marking off the sections at right angles. He preferred the use of a pocket level or clinometer to overcome difficulties in the side measurements. A parallel base line would also be necessary on top. Mr. Davies also discussed several other points, and advocated determining ore reserves off the floor plans, as being sections only 7 or 8 ft. apart, and suggested reading the staff inverted against the back as a safer method for measuring the height to the back in underground excavations. He mentioned the following factors:

	Cu. Ft. per Ton.	
Coal	39 17	(careful measurement of a truck)
Coal, Friable ore in place	40 8 4	(usual practice from a square set)
Run-of-mine ore	16	
Slime	20	
Tails	18	
Fine jig tails	7	

In his reply to the discussion Mr. Donaldson said that the two methods of measuring open cuts seem to be suitable for two classes of excavation, Mr. Matters' (theodolite) method being adapted to deep, more or less V-shaped cuts, and Mr. Davies' to flat-bottomed quarries, in which the irregularities of the sides do not greatly affect the volume. He also thought Mr. Davies' suggestion for inverting the staff in measuring stopes, etc., was good. He also gave the following factors:

	Cu. Ft. per Ton.	
Ore in place	9 5	(from measurement of stopes or several levels with known extractions)
Coal	40	
Run-of-mine ore	16	
Tails	19	
Slime	19	

Indian Gold Mines

The gold production of the Kolar field, in Mysore, India, in February was 41,888 oz. bullion, the smallest in a long time. This was due chiefly to a fire, which stopped production in the Nundydroog mine for a time. The output for two months ended Feb. 28 was \$1,807 oz. bullion in 1908, and \$8,019 oz. in 1909; a decrease of \$88 oz. The bullion reported this year was equal to \$1,654,158, or 80,027 oz. fine gold. The report includes two mines—the Hutti-Nizam and the Dharwar Reefs—in the Deccan.

In drifts at the Van Dyk Proprietary mines (*South African Min. Journ.*, Jan. 9, 1909), the average advance for each face throughout the mine was in December, 217 feet per month. There were seven drifts, five driven double-shift and two single shift.

Gold Dredging Ground in the Upper Amazon Valley*

The first mining concession granted by Peru for working the gold alluvials of the Inambari was confined to the torrential district and did not extend to the lower and far richer region. The gold here was discovered in connection with the india-rubber industry. The rubber men, while building a road down to and along the lower course of the Inambari as far as the head of navigation, discovered that natives and also their own rubber-pickers spent much of the time washing gold. Thus prompted, the English managers made experimental washings, and after professional assistance, an elaborately organized expedition was sent out from England, and more ground was examined with the same result. The gold from the Inambari resembles in form and quality the gold obtained from the Kaka. It is flat and relatively thick, having evidently been subjected to pressure after leaving its original vein. When a pan of gravel is washed the heavy residue containing the gold is a black sand. An analysis of a sample from the lower Inambari gives the following results:

	Per Cent.
Silica	8.50
Gold	0.27*
Silver	0.024†
Copper	0.55
Arsenic	0.50
Iron	37.10
Alumina	24.30
Titanic oxide	4.18
Manganese	1.50
Sulphur	1.57
Oxygen (by difference)	21.406
* 88.20 oz. per ton. † 7.84 oz. per ton.	

Thus far all we know about the Incachua and Inambari gravels is the result of exploratory expeditions; but companies are now proceeding to test these gravels by actual working, and their results will be watched with interest. All that the various experts have done is to ascertain surface richness. At Incachua, however, the ground was explored to a depth of 16 ft., and found to be equally rich all the way down. At no place has bedrock been reached, because the water poured in when the river-level was reached. Neither has the bed of either river been examined.

METHOD OF WORKING

Only one method of working these gravels is practicable, i.e., dredging; the ground does not fall steeply enough for sluicing or hydraulicking. At Incachua, for instance, and along most of the reaches of the lower Inambari (except where torrential side streams enter it) there are no boulders. On neither river, again, is there hard clay; the ground is loose, a mere compound of stones and sand. Again, at Incachua the bedrock is friable and easily scraped by the lip of

the dredge buckets, and a similar bedrock appears on the Inambari.

The current of neither river at the points of interest to the gold dredger is swift enough to cause any danger to the vessel. In flood time it can float over and excavate the banks, or can be worked in a paddock. During low river it can delve up the bed of the stream.

The transport of dredges to these remote places is difficult and costly; but in the case of the Incachua dredger a considerable part of the machine is said to have been already transported to the site. According to report, the Ollachea road presents no greater difficulties than does the Caravani.

EXTENT OF THE DEPOSIT.

The question that has to be answered is: What is the extent of these two dredging grounds? The answer can be only hypothetical. The only part of the ground on the Inambari or Beni rivers that has been examined by competent men is the Incachua basin, which contains about 10,000,000 cu.yd. of dredgeable gravel. Its surface has nowhere yielded less than 19d. to the cubic yard, while large areas of it average at least a dollar, and many places very much more. The bedrock value is likely to be much higher.

An average value of 3s. per cubic yard is not an extravagant estimate. Of course, local authorities put the average very much higher. At this rate the Incachua basin alone contains £1,500,000 worth of gold. For 100 miles below the Incachua basin it is believed that the Beni gravels yield gold; there are numbers of places where it has been definitely located, so that in all probability the Incachua basin is a mere fraction, probably not more than the hundredth part of the dredgeable ground on the Beni.

On the Inambari, if no spot has been so carefully examined as the Incachua, a much longer stretch of the river has been rapidly sampled by more than one expert, and values as high, for instance, as 22s. to the cubic yard have been revealed. The Inambari, therefore, is likely to yield as much gold as the Beni. The lower tributaries of both rivers are margined by gold alluvials.

LODE MINES

Something is to be expected, too, from the substance of the hills through which these rivers flow. At a point situated between the basins of the Inambari and the Beni, one gold mine has been worked for some years by an American company. Its output of gold is known to have run to several millions of dollars. During his explorations of the province of Caupolican Doctor Evans observed many signs of old workings in the rocks bordering the Beni. It is unlikely, then, that dredging will be the beginning and end of the exploitation of this region.

As far as we now know, all the indications seem to point to the conclusion that this part of the eastern slope of the Cordillera is a real goldfield of great size and importance. Its southern limit seems to be somewhere about the latitude of Mount Illimani; but as to the limit of its northern extension we know nothing. It will probably be long before we have exact knowledge over so large an area, so difficult of access.

Dense tropical forests render prospecting extremely difficult; only along the river banks has it thus far been seriously attempted. The climate at the level we are considering (about 1000 ft. to 2000 ft. above sea) is healthy; once plantations have been cleared, roads made, and suitable houses built, people can live there in comfort all the year around. All that is needed is a flow of population in this direction; for it is probably the richest but least developed part of the world.

Electric Motors in a Concentrating Plant

The concentrating plant at the Washoe smelter, Anaconda, Mont., was one of the first in the country to be driven by electric power exclusively, four large induction motors being used for this purpose. The concentration building is 600 ft. long, with the steam plant, heretofore used for driving it, located in the center. The jigs, tables, etc., are driven from a main line shaft 500 ft. long, to which the steam engines were connected by rope drive and friction clutch pulleys. The steam plant has been kept intact, to be used as a reserve in case that the electric power fails. The mill as a whole is divided into eight sections, four on each side of the engine room. Two induction motors are installed in each half of the mill, and connected to the main shaft by rope drive and friction clutch pulleys.

These large motors are notable because of their having squirrel-cage rotors, something unusual in motors of this size. Their guaranteed full-load efficiency is 91 per cent. and full-load power factor 92 per cent. Squirrel-cage motors were chosen because the starting conditions are favorable and the power factor of this kind of motor is higher than that of the wound-rotor type. The general construction of these large induction motors is practically the same as that of the smaller ones built by the Allis-Chalmers Company.

In addition to the four large motors and the 200-h.p. variable-speed induction motor for operating the pumps in the mill, the Allis-Chalmers Company also furnished for this plant three synchronous motor-generator sets of 300 kw. output each, and one small induction-motor generator set for starting and exciting the synchronous sets.

*From a paper by Sir Martin Conway, read before the Society of Arts, and published in the London *Mfn. Journ.*

Skips or Buckets in Sinking Vertical Shafts?

Sinking with Buckets Is More Dangerous, and If Much Water Is Encountered, More Expensive, While Timbering Is Much More Difficult

BY CHARLES B. SANER*

Most vertical shafts on the Rand have been sunk by means of kibles or buckets, with or without crossheads. All modern shafts on the Rand, South Africa, are rectangular; and until lately all the shafts were sunk with their long axes parallel to the strike of the formation, but now that the mines have become so deep that compound shafts are not economical, it has been found better to sink the shafts at the deeper-deep mines with their long axes in line with the dip, and at right angles to the strike.

In a number of instances hauling engines have been installed that cannot hoist from the extreme dip of the property in one lift, a grave error in design, so that the present amalgamation era will bring relief to many a mechanical engineer. Here I may be allowed to make a complaint, that those who design new plants, whether for surface or underground equipment, seldom take the trouble to consult those who have to work the plant; upon whom in the end the blame falls if things go wrong, but seldom the credit if all goes well.

Two methods are employed in sinking vertical shafts: machine drilling and hand drilling. Sometimes a combination of both methods is used.

SHAFT SINKING BY MEANS OF AIR DRILLS

On the Rand machine sinking has been proved less expeditious and more costly. The great drawbacks are the necessity for irregular working shifts, both for drilling and shoveling, and the raising and lowering of the gear that causes loss of valuable time. If the formation passed through is in any way disturbed, the heavier charged machine holes break wider and make the sides of the shaft bad and heavy while more timbers are broken than when the shaft is sunk by hand. If the cut does not come, the whole round is hung up; that means loss of time and added cost in blowing out the holes and reblasting.

At the Village Deep No. 2 shaft, as native labor was scarce immediately after the war, sinking was done by machines and shoveling by one gang of 20 whites and another of 20 natives. The best footage done was in October, 1904, when 150 ft. was sunk in 31 days, a world's record for machine sinking.

Twelve machines were used on four bars; the cut holes were drilled 9 to 10 ft. deep and the other holes 8 to 9 ft. deep. The details are: Number of rounds drilled in the month, 20; average number of holes per round, 32.5; average time drilled, 8.28 hours; average time cleaning out, 27.27 hours; average time per round, 37.40 hours; average depth sunk per round, 7.5 ft.; number of ton buckets of rock broken per round, 231.

The whole round was blasted together, and it took two shifts to clean out; a task of 80 buckets was set for the first shift, and the second shift cleaned up. The sockets of the holes were then blown free of dust with compressed air, and again charged and blasted, the first shift coming in again and completing the cleaning up. Two engines and buckets were used. The timber was usually lowered just before the drilling shift went down—to wall plates, or five sets at a time; the filling-in was done during lashing.

This method is bad, as there are no allotted hours of work for the men; this generally resulted in a rush. But as far as could be seen, no better system could be devised, as it was no use blasting the round until every hole was drilled to the proper depth; one awkward hole delayed the whole shaft. The great job of loosening the bars and machines, raising the hoses and bringing everything to the surface, is an undertaking that operates against speed in machine sinking—not to mention the waste of labor which, in order to be available, at any time day or night must be paid for, but which half the time is unemployed.

SHAFT SINKING BY HAND DRILLING

It has been stated that where very hard ground or water is met with, machines will replace hand labor; but I fail to see it. The hardest ground can be more cheaply and as effectively sunk through by hand as by machines.

In the Turf Mines shaft a very hard dike was passed through and a square shaft cut by hand. If machines had been used, the blasting of the large holes would have made a wide ugly shaft, necessitating extra timbering, and the hauling and shoveling of unnecessary rock. With hand labor excellent results have been and are being obtained. The shaft is cut almost to exact required size, regular shifts are employed, and greatly increased speed has resulted.

In the latest large seven-compartment shafts the method of procedure is some-

what as follows: Three 8-hour shifts were worked, consisting of from 75 to 85 boys, under the charge of a white sinker and an assistant. The rock broken by the previous shift is shoveled into buckets or skips, and then from 35 to 45 holes from 30 to 50 in. deep (according to the nature of the rock) are drilled, mostly double hand, and blasted in the eight hours.

The holes are usually put in at right angles to the dip of the formation (or even flatter). When the shaft is sunk with the dip, practically no sump is carried, but instead a sort of vertical stope face, with the benches well defined, the north and south ends being, as a rule, a little higher than the center. With the formation dipping 30 to 40 deg., as in the central Rand, most of the rock in blasting is hurled to the north or rise end of the shaft, so that shoveling is mostly at one end. This is a serious drawback, as rapidity of sinking depends upon the speed of getting out the broken rock. The more time there is to drill, the deeper the holes, and the better the footage.

Various forms of receptacle are used to clear out the debris from the shaft bottom—cages carrying one or more trucks, buckets and skips. Mention is only made of the first as an old, and, as far as the Rand is concerned, a disused system. The other two systems are used on the Rand, and have ardent advocates. I will endeavor to give the advantages and disadvantages of each, claiming that privilege, as I have had experience with both.

Although it may be presumption on my part to criticize well known experts, I may mention that all those who have sunk with both buckets and skips have no hesitation in their preference; while those who have only had experience with buckets, naturally pin their faith to that system, knowing little of the other. In the large shafts two engines are usually employed, and to the winding ropes are attached buckets or skips.

SINKING WITH BUCKETS

Buckets are made of iron or steel and have a capacity of 10 to 20 cu. ft., they are usually oval or cylindrical in shape, about 4 ft. high, and attached to the rope by a ball-bearing swivel, to bale or bow, or by a chain of iron or steel, bent to form a loop in the middle or provided with a hole for attachment. Some buckets are hung just above the center of gravity, and are held in position by two fingers above the bucket, which are turned back when

*Mine manager, Turf Mines, Johannesburg, South Africa.

Note: Abstract of a paper in the *Journal of the South African Association of Engineers* for October, 1908.

dumping. Other buckets are hung by a chain, with a large link in the middle, attached to two lugs on the top of the bucket, and are tipped by inserting a hook in a ring at the bottom of the bucket and allowing the winding rope to lower slightly.

The bucket may also be tipped on inverted V-hinged doors, or into a swinging chute. Four or more buckets are always in use; the great secret is always to have two in the bottom being filled. Cross-heads of various makes are used to keep the bucket from swinging too much in the shaft.

An empty bucket is lowered by the engineman to within 10 ft. of the bottom, and on the signal to lower, he does so slowly. The sinkers below seize the bucket and push it to the desired position most suitable for loading, and detach the rope at once. Meanwhile the bucket on the other rope of the same engine, which is at the surface, is tipped. The rope in the shaft bottom is then attached to a full bucket, and on the signal being given, is raised slowly about 5 ft., is steadied vertically below the rope by the shaftmen, and then sent away. The engineman slows up on taking the cross-head at the timbers, which are from 40 to 140 ft. above the bottom of the shaft, and then speeds up to surface. From the bottom of the timbers the bucket is free to revolve, and sometimes does at a great speed before engaging the cross-head.

The buckets being usually of small diameter the shovelers can crowd around for loading. When nothing but dry rock has to be handled the bucket is very adaptable; but if any quantity of water has to be baled as well, its drawbacks are soon manifested. The steadying at bottom and tipping at top cause serious delays. The carrying capacity is limited, and it cannot with advantage be made much larger. When lowering timber and boys, limited capacity of the bucket is again a serious drawback; and when taking timber out at the bottom set, it is dangerous on account of its swinging. Drills can be lowered to the bottom, and, by overturning the bucket, are at once deposited on the shaft bottom. Few repairs are necessary for upkeep. Small-diameter ropes can be used—a saving in cost.

Many more trips are required to lower and raise the boys and material and timber, 6 to 8 boys only being carried at once. A form of bucket used by me was oval in shape, only 3 ft. high and from 3 to 3 ft. 6 in. diameter. It was easy to shovel into this bucket, and because of its shape the bucket was not so liable to catch in the timbers; but it was not very safe for boys to ride in, as they might be jerked out.

In blasting with buckets, after the warning signal has been given, the driver raises the bucket a few feet and lowers again. He is liable to let out a little slack rope,

and on account of the irregular bottom, especially in shafts cut with the dip, the bucket will not stand upright nor steady; when the "rightaway" signal is given, the engineer takes the bucket away too quickly. This causes swinging, and there is every chance of fouling the timbers. Because of this swinging, a bucket cannot safely be quite full.

It is difficult to examine and clean down the shaft timbers and sides, especially between the last set and the bottom of the shaft—the place from which most of the rocks that cause accidents slab off. As it is almost impossible to remove bad or loose ground from a swinging and revolving bucket, the slab is left, with the hope that it will hang there until the timber reaches it. When using buckets in timbering, several sets are usually hung at a time; this means a rush of work for the timbermen, and then a slack time. The timber being farther away is little damaged with blasting. In some shafts extra boys are stationed on the timbers to steady the ascending bucket before it takes the crosshead.

SINKING WITH SKIPS

Skips are rectangular boxes of steel or iron, supported on the bottom by a shafting on which the box revolves, and in a framework with shoes running on guides. These shoes, during sinking, are 18 to 35 ft. long; the skips are self-dumping, and have a capacity varying from 20 to 40 cu. ft. The following are the dimensions of a skip frequently used: Three ft. 8 in. by 3 ft. 8 in. by 3 ft. 6 in. high. The important point is to have the loading box low enough so that rock can be thrown in over a shoveler's head from anywhere in the shaft. In the large shafts the best arrangement is to have one engine running the two skips in Nos. 2 and 3 compartments, and the other engine to run in Nos. 5 and 6 compartments.

The native gang is divided into three parties so as to have a regular set of men in each of Nos. 1, 4 and 7 compartments. Each party is again divided into two shoveling and one picking units.

One skip comes to the bottom, and 12 to 14 boys immediately load it—5 on each side and one at each corner, throwing over his shoulder. Immediately the skip is full—and it can safely be filled quite full—it is rung away and the driver can pull away and gather up speed at once. Meanwhile the pickers loosen the rock while the other skip is descending. When the empty skip gets to the bottom timbers, the loaded skip is tipping automatically, and no time is lost. After tipping the skip is drawn farther up the headgear, there being 30 ft. of head room above the tip, while the other is lowered in the shaft bottom. Loading is begun at once.

The timber is kept 20 to 30 ft. away from the bottom; short, temporary, 6-ft. lengths of steel guides are put downward

projecting 3 ft. below the last set of timber, so that there is never any chance of the skip's shoes coming out, thereby insuring perfect safety.

When six 6-ft. lengths are in, they are taken out in one lift of two 36-ft. guides, and the permanent steel guide, 30 ft. long, with a temporary 6-ft. length, fastened by fishplates to the lower end, so as to take any blows of rocks from blasting, is bolted securely in place.

To take out the two 36-ft. lengths and bolt the two permanent lengths in place takes only from half to one hour, and is done while the bottom is being drilled over; that is, between 12 and 2 midday. The holes in the dividers are drilled on the surface before the dividers are sent down, and the steel guides punched from measurements taken in the shaft.

One set is lowered at a time, and the system adopted is as follows: First thing in the morning the timbermen descend and, while the debris is being cleared up from the shaft bottom, block the set lowered and filled in the day previous; then when the boys are drilling and the engines are free, four half-wall plates are hung in pairs and filled in 1 to 1½ hours. The corners are temporarily blocked and the short guides bolted on. The sides and ends, between the two bottom sets, are carefully examined and all loose rock is taken down. Thus the shaft is being examined and trimmed down daily, and if there is any dangerous rock, the boys can easily be moved to one side by shouting, and the rock dislodged and sent to the bottom without any mishap or delay, it having no distance to fall. When the wall plates are being hung, the south skip of one engine and the north skip of the other engine (skips in 2 and 6 compartments) are filled with the end pieces, studdles and dividers, and with compartments 1, 4 and 7 staged over, the filling in of the set is soon done, for one more skip load, or three in all, completes the whole set. All this timber can be taken out of the skip easily and with comparative safety, as the skip does not swing.

Skips have to be periodically repaired, for the liners to shoes and other parts wear out. Large diameter ropes have to be used; there is greater safety with skips than with buckets; better and more work is done, and, given equal conditions, just as great speed can be made.

I may mention that at the Turf mines, while sinking with skips from a depth of from 640 ft. to 3007 ft., there has not been one blasting accident, and only two from falling rock, which came from faulty ground.

During drilling, the sides can be easily examined and loose rock can be removed with safety from the timbers. A skip can be well filled, and when the signal is given, it is at once hoisted to the tip, with no jar or trouble, and automatically emptied. If the rope winds badly on the drum, there is no danger to the skip as the shoes run-

ning on the guides prevent its swinging, and there is also regularity of work.

Greater loads can be handled at one time, and the capacity of the skip can be increased while that of the bucket is limited. If water is met with and has to be handled before pumps can be installed, buckets are out of it, whereas skips can easily handle a fairly large quantity.

At the Turf mines the shaft has been cleaned up, one set blocked, another lowered and filled in, two 36-ft. lengths of temporary steel guides taken out, and the permanent ones put in place in seven hours, and without delaying the sinking operations below.

COMPARISON OF THE TWO METHODS

Excellent work has been done with both buckets and skips, but up to the present, because of meeting the most favorable conditions, buckets have done the quicker sinking.

It is impossible to make comparisons between two separate shafts, just as it is impossible to compare two adjacent mines as to working costs, or profit per ton—so many factors affect the issues, such as dip of ground, hardness and stratification of rock passed through, quantity of water, dikes, etc. The following are the best performances with each appliance:

At Brakpan No. 2 shaft, 204 ft. were sunk in one month and an average of 161 ft. in 14 months; the dip of the formation was about 8 deg. This was done with buckets.

At Turf mines, 162 ft. were sunk in one month, and an average of 143 ft. in 14 months; the dip of the formation was from 32 to 44 deg. This includes one month when only 87 ft. were sunk owing to faulted ground necessitating stoppage for extra timbering. During the 14 months four dikes, totaling 98 ft., were passed through. This was with skips.

In examining the published statistics of accidents, the following figures are significant: From 1903 to 1907 there were 15 fatal and 15 nonfatal accidents due to the swinging of the bucket. From July 1, 1903, to Dec. 31, 1906, accidents due to the swinging of the bucket or the cross-heads catching, men standing on edge, or rock falling out of the bucket or skip were, with buckets, 57; with skips, 8. Between 1902 and 1908 the number of accidents, including falls of rock from shaft sides, or out of tip (excluding blasting accidents) were, with buckets, 97; with skips, 23. Unfortunately I have been unable to get the exact footage sunk by each method during that period.

In reading the evidence given before the Rope and Safety Catch Commission, one is struck by the diversity of opinion expressed by the advocates of each system, but one notices that those who have used both buckets and skips are almost all in favor of the latter, and to that opinion I most strongly adhere.

Raising Liquids by Compressed Air

The use of compressed air in pumping, especially from deep wells, is increasing on account of the simplicity of the system and the low cost of maintenance. In this method there are no moving parts; the only requirement is that the size, length and connections are properly designed so as to obtain maximum efficiency. Still, while pumping by compressed air is simple, the problem is better solved by tests than by mathematical calculations. The Westinghouse Air Brake Company, of Pittsburg, has lately completed a series of

WESTINGHOUSE AIR-PUMPING INSTALLATION

nearly 2000 tests covering a range of from 350 to 400 different conditions in deep-well pumping in order to obtain data concerning the amount of water delivered, air consumed, and the best proportions for and arrangement of piping and apparatus. The accompanying illustration shows the system as frequently installed by that company.

The council of the chamber of mines of Victoria has passed a resolution emphatically protesting against the "very lenient and inadequate sentences" given by magistrates in many cases of convictions under the Gold-buyers Act. Members expressed the opinion that the crime of gold stealing will never be checked while lenient sentences are given. In recent cases fines of £1 and £2 10s. have been assessed for offenses against the act—amounts which the council considers altogether inadequate.

The London Silver Movement

The imports and exports of silver in Great Britain are a matter of much importance, since London still remains the great silver market of the world, and by its fluctuations the prices and movements of silver are largely governed. The totals of this movement have been given heretofore; in the following tables the details are stated, as they are reported in the annual statement of Messrs. Pixley & Abell. According to this statement the imports of silver into London for two years are valued as below:

From:	1907.	1908.	Changes.
United States.....	£11,961,701	£ 8,305,976	D. £3,655,725
Canada.....	129	240,532	L. 240,403
Mexico and S.....			
America.....	255,515	211,267	D. 44,248
Australasia.....	125,944	120,241	D. 5,703
Africa.....	54,917	196,469	L. 132,452
India.....	1,218,473	271,000	D. 947,473
China.....	377,485		D. 377,485
The Straits.....	958,144	46,666	D. 911,478
European countries.....	997,138	924,713	D. 72,425
Other countries.....	25,342	10,925	D. 15,317
Total.....	£15,983,892	£10,326,889	D. £5,657,003
Approx. ounces.....	55,660,500	46,883,600	D. 8,776,900

The total imports do not include silver in ores, which was valued at £2,244,030 in 1907, and £2,148,680 in 1908; raising the approximate quantities imported to 63,588,000 oz. and 56,639,000 oz. in the respective years. The decrease in values was much less than that in quantities, owing to the lower average price of silver in 1908. It must be remembered that a considerable part of the imports credited to the United States is derived primarily from Mexico, and a smaller portion from Canada; this silver being smelted or refined in this country from ores and base bullion from those countries. The British returns, of course, are based on the port of last shipment.

The exports for two years are reported as follows:

To:	1907.	1908.	Changes.
India.....	£11,163,424	£ 8,836,820	D. £2,326,604
The Straits.....	1,029,356	584,848	D. 444,508
China.....	559,450	822,300	L. 262,850
Total.....	£12,752,230	£10,243,968	D. £2,508,262
Africa, Inc. Egypt.....	1,057,252	281,800	D. 775,452
Australasia.....	372,130	163,750	D. 208,380
United States.....	660	260,598	L. 199,938
Canada.....	135,298	35	D. 135,273

While the decrease in values was 21.5 per cent., that in quantities was only 3 per cent.; this difference being due to the lower price of the metal in 1908. The causes for the decline in values have heretofore been explained.

In New Zealand applications for assistance in prospecting operations are presented to the local governing body, or a miners' association, which body may make a recommendation to the minister.

Electrically Operated Coke-squeezing Machines

By ALFRED GRADENWITZ*

The use of electricity in connection with mining and metallurgy has brought about a revolution in these branches of engineering work; electric operation has been adopted everywhere, not only in connection with the main work, preferably to other methods, but also with accessory operations, owing to the small space requirements and high safety characteristic of the electro-motor. This power is also used to facilitate handling, as is shown by electrical controlling apparatus in connection with all kinds of lifting and charging machinery.

Electro-motors have thus found an interesting scope in connection with the operation of coke-squeezing machines, as is

ing gear or the driving gear of the stamp. In some special cases, however, other equipments, including two motors, are preferred, one motor being used in actuating the stamp.

Fig. 3 shows an outside view and the electric drive of a coke-squeezing machine used in the Prinzregent mine, near Bochum. As in most plants of this kind, the coke ovens have been constructed with a view to arranging the several compartments like batteries, in long rows, one beside the other. Each of the compartments is about 2 m. in height, 6 m. in depth and 7 m. in width; at either end there is a door, enabling the coke cake, formed from the mineral coal, to be removed with the aid of a long stamp.

The coke-squeezing machine is installed on a fairly heavy truck, running on six wheels, and carrying the driving gear with a movable stamp. The latter comprises a substantial iron shield of about

leys, fixed, as seen from the figure, to a framework pole. In order to protect this against atmospheric influences, the truck of the coke-squeezing machine is covered by an undulated sheet cabin.

ALTERNATING CURRENT AT 1000 VOLTS IS USED

Fig. 4 shows the drive of a coke-squeezing machine of the mine Rheinpreussen, near Homburg, where alternating-current at 1000 volts is used. A 30-h.p. alternating-current motor is designed with pole-switching for two different numbers of turns. As seen from the figure, a double controller and two stator oil-switches have been provided for steering the machine. The rack is moved in the direction corresponding to the coke-squeezing operation, at a lower speed, agreeing with the smaller number of revolutions of the motor, and in withdrawing the stamp, at higher speed.

In both of the plants above described,

FIG. 1. INSIDE VIEW OF ELECTRICALLY OPERATED COKE-SQUEEZING MACHINE

FIG. 2. INSIDE VIEW OF COKE-SQUEEZING MACHINE IN "PRINZREGENT" MINE NEAR BOCHUM

illustrated by the accompanying photographs.

OPERATION OF THE MACHINES

Coke-squeezing machines are transportable devices serving to squeeze the ready-made coke out of the retort by means of a stamp. Four operations would have to be performed in this connection; first, right-hand traveling of the machine; second, left-hand traveling of the machine; third, introduction of the stamp into the retort; and, fourth, withdrawing of the stamp from the latter. An essential requirement of this kind of machinery is that the traveling motion and the operation of the stamp should never be carried out simultaneously; therefore, the operation generally requires only one reversible motor, starting from its position of rest under full load, and being connected by a clutch, as the case may be, to the travel-

the cross-section of an oven, and which is carried by a long rack, running on long rollers and being moved in a horizontal direction by gearing. The driving mechanism consists of a 45-h.p. direct-current Lahmeyer motor, running at a speed of about 1000 r.p.m., under a tension of 220 volts, and operating the rack through a multiple-toothed wheel gearing. In order to allow the ovens to be discharged successively, the whole machine can be made to travel on rails in a direction parallel to the ovens. The same motor which is used in moving the stamp, also serves for driving the truck, to which effect it is switched over by means of a clutch to the driving gear of the truck.

A Universal controller is used in steering the motor, all operations being controlled by the same apparatus. An armature short-circuit brake serves to instantaneously stop the motor.

Current is supplied to the motor in a way similar to tramway motors, by trol-

the same motor is used in actuating the squeezing machine, and in effecting the traveling motion of the whole system, by the aid of a mechanism operated with the hand lever visible in the figure.

In the department set apart for the working of by-products at the works of the Eschweiler Mining Association, two coke-squeezing machines have been equipped with Lahmeyer motors; with each of which there is used a 40-h.p. motor running at 750 r.p.m. under a tension of 500 volts. Fig. 1 shows one of these drives, the motor operating both the machine-traveling gear, squeezing stamp and planing rod. After the traveling gear has been thrown out by the aid of a hand lever, the two latter are likewise moved with a hand lever until a tooth of the rack engages with a toothed wheel arranged below the same, when the rod is moved out by the motor-actuated gear.

In Fig. 5 are seen two coke-squeezing machines, installed for electrical operation

*3, Regensburgerstrasse, Berlin W. 50, Germany.

in the Röchling Iron and Steel Works at Voelklingen. Each of these machines comprises an alternating-current motor, which effects the motion of the squeezing rod, and after causing a wheel gearing to engage, also causes the traveling motion. The output of each motor is 30 h.p. at 1000 r.p.m., at 400 volts tension, and 15 h.p. at 500 r.p.m., the low number of turns

Coal-mine Legislation in Kansas

The new Kansas legislation forbidding the use of explosives in coal mines became a law last week. The new law provides:

"Section 1. It shall be unlawful for any person or persons engaged in coal mining

"Section 2. It shall be unlawful for any person, firm, or company to direct any of its or their employees to go into any sinking shaft or development work in a coal mine, after shots have been discharged in which dynamite or other detonating explosives have been used, before having removed all smoke, gases or other unsanitary conditions that may have been

FIG. 6. INTERIOR OF MACHINE SHOWING ARRANGEMENT OF THE MACHINERY

being required in coke-squeezing and in moving the pressure rod, and the high speed, in withdrawing the rod.

Fig. 6 finally shows the drive of a coke-squeezing machine, a distinctive feature of which is the fact that special motors are used in operating the traveling gear and squeezing stamp respectively. The two 4-pole direct-current motors, in addition to the starting and controlling apparatus, have been constructed by the Lahmeyer company for an iron and steel works in Upper Silesia.

to use or cause to be used dynamite, or other detonating explosives in the preparation of any blast or shot in any coal mine within the State of Kansas; provided, however, that dynamite or other detonating explosives may be used under such rules and regulations as may be agreed upon between the employer and the employees, same to be approved by the State mine inspector. All rules, regulations and permits to use dynamite or other detonating explosives as herein provided, shall be in writing.

created by the use of dynamite or other detonating explosives.

"Section 3. Any person violating the provisions of section one of this act, shall be deemed guilty of a misdemeanor and upon conviction shall be fined in any sum not exceeding twenty-five dollars.

"Section 4. Any person or corporation violating the provisions of section two of this act shall be deemed guilty of a misdemeanor and upon conviction shall be fined in a sum not exceeding one hundred dollars."

Coal Cutting by Machinery in England

By J. HINTON*

American readers may be interested in the following notes, which express the opinions of English mining experts on the subject of coal cutting by machinery. During the last 10 years or so, the question of coal cutting by machinery has commanded a considerable amount of attention in Europe, and English mining engineers have been more disposed to examine the economic advantages, which are claimed to result from the employment of coal-cutting appliances.

It has been found that when the coal seams and other conditions are favorable, the output per man may be doubled when machines are used, while the cost of production is appreciably reduced and an increased value of output per ton is obtained. *In specific cases the cost per ton has been 42c. where hand labor had cost 60c.; the output per man being 4 1/5 tons as compared with 2 1/2 tons. The proportion of round coal with machines, has also been raised 25 per cent, and greater safety has been insured to the miner.

MACHINES AFFORD GREATER SAFETY

At one English colliery there was a serious accident when the work was done by hand for every 77,000 tons of coal mined; the proportion when machines were introduced was only one serious accident for every 450,000 tons produced.

It must be confessed, however, that in some seams machines have proved unsatisfactory; this is the case in what may be called the South Wales area, embracing the Cardiff and Swansea districts. The united coal output of these districts is not much short of 50,000,000 tons per annum, but the amount won by machinery last year was only 105,000 tons, the number of coal-cutters in use being only thirty. Two of the probable reasons for machines not finding favor in the South Wales area are that comparatively little holing is required, while the roads are of such a nature that close propping is absolutely necessary for safety. It is not likely that there will be any increase in the employment of cutters where the coal seams are thick, and lines of cleavage occur with regularity, so that there is not much labor required in working the coal.

Some statistics for 1906 and comparisons with former years will show what progress has been actually made in the introduction of coal-cutting machinery into English mines. In 1906, coal was raised from 3205 mines in Great Britain as compared with 3461 in 1902; the number of machines at work during 1906, was 1136, which compares with 483 in 1902, an addition of 653 cutters. From this it will be apparent that except in South

Wales, machines are rapidly growing in favor, a considerable proportion of the increase occurring in the East and West of Scotland, Yorkshire, the Midlands and Durham.

ELECTRIC POWER VS. COMPRESSED AIR

The driving or motive power, continues to be a debatable point. In Scotland, electricity is chiefly in favor, 171 machines being driven by it; 134 are driven by compressed air. Electric power has grown in favor most rapidly. On the other hand on the Newcastle, Durham districts compressed air is used for 140 machines, while only 79 are driven by electricity. In Yorkshire the proportion is 158 to 94, and in Lancashire 146 are driven by compressed air and only 14 by electricity.

The total coal production of the United Kingdom in 1906 was over 251 million tons; in 1902 the output was about 227 million tons. Of this production, the machine-mined coal in 1906, was 10,202,000 and in 1902, only 4,161,000 tons. A simple calculation shows though the experimental stage has been passed, the production per coal-cutter has only increased from 8615 to 8981 tons. The increase in the number of machines and the total output from them is, therefore, more significant than the amount of coal obtained by each machine, the reason probably being that a great many machines were started too late in 1906 to appreciably affect the output. A broader view of the question of coal cutting is now being taken; the miners do not now object to the use of the machines as they did some ten years ago; in 1902 only one ton in fifty was machine mined, while in 1906 the proportion was one in 25.

Many experts are of the opinion that coal-cutters are of considerable value in thin seams. It is the experience of many English authorities on coal mining that if the mining and hauling price in a seam worked, is less than 60c. per ton, a cutting machine would hardly effect an important economy. This probably explains why in the Midland districts of England, where 33 1/4 million tons of coal are annually obtained, there are only 140 cutters, while there are about 176 cutters in the east of Scotland, where the total output is not much in excess of 19 million tons.

Danger is feared from electrically driven machines in fiery or gassy seams. Some engineers suggest that in fiery mines, suitable air compressors should be erected and driven by electric motors, duly incased and placed in main intakes at safe distances from the face, and that the coal-cutters should be driven by compressed air from them. This method would be a practical and useful adaptation of electricity to the present method of working by compressed air, thus avoiding the serious risk which would be incurred by carrying the currents to the faces.

The advantages of coal cutting have been summed up as follows: An increased

percentage of large coal is obtained, and the coal mined is in a firmer and better condition; a more regular line of face is obtained leading to more regular and systematic timbering; increased safety conditions for the workers; thin seams can be profitably worked; less small is made than in holing by hand; increased output and greater regularity; facility of supervision. Fewer explosives are required for getting down the coal and in some cases none.

The Cost of Diamond Drilling for Coal in Pennsylvania

By E. E. WHITE*

The following notes on progress and cost of drilling in the coal measures of Greene county, Penn., were taken from April 20, to July 13, 1908. I was on the ground practically all of the time, representing the company who had optioned the coal, and so had a chance to obtain correct figures on the progress of drilling. The costs are not as accurate, but are essentially correct.

The cost of superintendence and carbons is estimated. The superintendent, C. C. Hoover, of the Birdsboro Steel Foundry and Machine Company, which concern took the contract for drilling, was on the ground only one day. As he was looking after about half a dozen other drills, the estimated cost for superintendence is liberal. The cost for carbons would have been much less but for the fact that 2 1/4 carats were broken at a depth of 21 ft. in the first hole, probably by a piece of steel in the hole. This bore was abandoned and another started 2 ft. away.

The drill only worked a day shift, and was run by two men, the drillman, H. N. Wigham, and a fireman. Bits were set in the company's shop, not in the field. The hours in the progress table refer to the drill, that is, to two men, except in the case of hours setting bits.

The drill had a hydraulic feed and a double-core barrel, taking a 2 1/2-in. core. This type was described by W. F. Murray in the JOURNAL of Feb. 23, 1907, and by the Sullivan Machinery Company, in *Mines and Minerals* for October, 1906. The outfit, with one good diamond bit, is furnished by the Birdsboro Steel Foundry and Machine Company, of Birdsboro, Penn., for about \$3500.

BOILER AND PUMP TROUBLE

Considerable trouble was experienced with the boiler on the first two holes, which was accountable for a large part of the hours' delay on these holes, shown by the progress table. The boiler was of the upright type, set behind the machine on the heavy wagon frame. There were

*87, Atlantic Chambers, Manchester, Eng

*Carterville, Missouri.

no stay bolts, and the flues frequently had to be rolled every three or four days after the first week, and finally were rolled every day for three days in succession. After stay bolts were put in, the flues were not rolled again on the job. Except for the boiler and a troublesome donkey pump which supplied the water tank, the outfit was excellent. The delay on the last hole was mostly waiting for water, which had to be pumped a little over a quarter of a mile.

The expense of pumping on the last hole is not included, as it was borne by the owners of the coal. The contract read that water should be furnished within 100 ft. of each hole. The cost of moving on and off the ground is not included, as it would be variable, according to the distance and means of transportation. The distance moved between holes averaged about a mile by road. It was open country with good roads, so that moving was not expensive.

The core obtained was practically complete, both of rock and coal. The surface was from 6 to 10 ft. deep, averaging

RATE OF BORING.

Kind of Rock.	Ft. per Hour Actual Cutting.
Shale	7.05
Fireclay	7.10
Limestone	7.20
Sandstone	9.35
Coal	15.15

COST TABLE.

	Cost, per Ft.	Cost, Actual
Drillman	\$307.70	\$0.169
Fireman	192.31	0.106
Blank bits	5.00	0.003
Setting bits	10.00	0.005
Carbous (44 carats at \$90).	382.50	0.210

Feet per drilling hour*	4.05	5.05	4.75	5.15	4.15	4.49
Feet per hour actual cutting*	6.94	8.95	7.95	8.62	7.50	7.82

† Excludes 20 hours putting stay bolts in boiler.

* Excludes hours setting bits.

9 ft. 9 in. It was clay, with no boulders, and was drilled out with a mud bit.

The table showing rates of drilling in different kinds of rock is the average of many observations on the five holes. The rate is, of course, dependent largely upon the drillman and how much pressure he cares to put upon the bit.

Both cost and progress tables are from the time the drill reached the ground until ready to leave:

BITS USED.

	Distance Drilled.	Estimated Carbon Wear.
Mud-bit	48 ft. 7 in.	
Diamond bit No. 1 (carbons broken by steel?)		24 carats
Diamond bit No. 2 (hole No. 1)	369 ft. 8 in.	4 carats
Diamond bit No. 3 (hole No. 2)	339 ft. 0 in.	4 carats
Diamond bit No. 4 (holes Nos. 3, 4)	500 ft. 1 in.	4 carats
Diamond bit No. 5 (hole No. 5)	562 ft. 8 in.	4 carats
	1820 ft. 0 in.	44 carats.

SPECIAL CORRESPONDENCE

Professor Gréchant, of the Académie de Médecine in Paris, has been reporting the result of the studies he was entrusted with by the Ministre de l'Instruction Publique on ankylostomiasis. This disease is due to the presence of a worm inside the intestinal tube. The larva enters the system either by the mouth or through the skin and makes its way to the duodenum where it settles. The eggs only develop in the open air, when eliminated from the system, on the soil of the mine

galleries at a temperature between 20 and 30 deg. C. Thus one man who is infected, can contaminate many fellow workers. In many mining centers, such as Anzin, Mons, Liège, every man undergoes a medical examination before being engaged. The diagnosis of ankylostomiasis is obtained by means of a microscope of 400 diameter magnifying power. The most effective cure for this disorder seems to be a mixture of etherized extract of male fern and castor oil, taken in pills or by spoonfuls for about a week.

Thanks to the precautions that have now been taken for some time, the disorder has notably decreased, but Professor Gréchant doubts its ever disappearing entirely owing to the tenacity and extreme mobility of the larvae.

Temporary Fire Walls for Coal Mines

Near Saarbruck, in Rhenish Prussia about 40 miles in a southeasterly direction from Treves on the Saar, a unique type of temporary barrier is used for inclosing burning portions of coal mines. By this system a speedy shutting off of all air supply is accomplished which is the first necessity in dealing with underground fires.

The Prussian method is peculiar in the material used for building the temporary fire-walls. It is hay, compressed in the form of blocks. The material is so light that two men can, in half an hour, erect a tight wall across an ordinary entry, and furthermore, the wall will be air tight.

This is accomplished simply by filling up the cracks between the blocks with loose hay and then sprinkling the wall with water. The water causes the blocks to swell so that a perfectly air tight barrier is made shutting off all air supply, through the entry, to the fire. Behind the temporary wall a more permanent wall may be erected if the conditions warrant. In case of overpowering gases or smoke, the miners wear a smoke hood to enable them to breathe as they are erecting the partition. In commenting, *Der Bergbau*, Feb. 25, 1909, says this scheme has proved highly successful at the mines where it has been tried.

At the Komata Reefs mine, New Zealand, where the Brown (Pachuca) agitation tank was originally, and is still, used, the ore is crushed by 20 stamps through 4-mesh screens, and fine-ground in two 16x4-ft. tube mills so that 60 per cent. of the pulp will pass through a 200-mesh screen. The pulp is separated into sand and slime. The slime is agitated in high tanks, while the sand is treated by percolation. The extraction on the gold is 93 per cent. and on the silver 83 per cent. The value of the ore treated is about \$8.75 per ton.

Notes on Tin Ore Dressing at South Crofty

At the meeting of the Institution of Mining and Metallurgy held at London in November, 1908, H. W. Hutchin described an instructive set of investigations on tin-ore dressing performed at the South Crofty mine, Cornwall, England. The work covers in particular the preparation of concentrates for the calciner.

The plant at the South Crofty, recently enlarged, now has forty 1050-lb. stamps and a Cornish battery of 30 heads, operated under a 7½-in. drop and at the rate of 102 drops per minute. All the machinery is electrically driven, everything being controlled from one board in the motor house. There are four 30-h.p. motors, one driving each section of 10 stamps. The cam shaft is so arranged that only five stamps need be hung up at a time when repairs are necessary. The 40 new stamps give a capacity of 3500 tons per month.

In the new part of the mill the pulp flows from the stamp battery to Lührig patent classifiers which deliver four sizes of product all carrying more or less slime. The firsts pass directly to six Buss tables, producing tailings, middlings and concentrates, the seconds and thirds to 16 Frue vanners and the fourths partially to each. There are also three barrel pulverizers driven from overhead shafting by a 20-h.p. motor. Frues and Buss tables are driven by two 20-h.p. motors. This scheme of treatment gives a cost of milling and dressing of 33.6c. per ton.

The ore treated is of a complex nature with an average value of 25 lb. of tin and 12 lb. wolframite per ton, 0.25 per cent. metallic copper, and 1.5 per cent. arsenic, in a gangue of quartz, feldspar, mica, tourmaline, chlorite and fluorspar. The accompanying table of determinations of concentrates gives an idea of the nature of the ore.

Nature of Concentrates.	Tin.	SuO ₂ .	Wolframite.	Copper Pyrites	Mispickel.
1. Firsts	46.1	7.08	3.48	2.89	11.4
2. Seconds	46.22	4.61	2.92	2.89	8.3
3. Thirds	46.85	4.74	3.33	3.03	7.25
4. Slimes	42.39	5.18	3.93	2.75	11.03
5. Firsts	26.47	10.87	5.00	1.87	24.5

The first four in this table are concentrates from development stuff, the last one from stoping ore.

THE SAMPLES

For the systematic investigation of the battery tailings only tin was determined and reported as pounds of cassiterite per ton. The assays were all made by reduction with zinc vapor after the improved method of J. J. Beringer, of the Camborne School of Mines. Dip samples were taken from the tables and from the joint

tailings of the mill. These tailings were deposited in a series of ponds so that check samples of the accumulated tails could be taken.

Three samples were taken from the stream carrying the joint tailings from the battery. The first, in which water and sediment were allowed to run into the overflow from the bucket, thus saving practically only sand, gave an assay of 2.5 lb. per ton. The second, where overflow was avoided assayed 7.9 lb. per ton, and the third, taken in the same manner, gave a value of 6 lb. per ton. In this case a screening test was made with a 60-mesh sieve, that which passed through being separated into fine sand and slime by decantation. The results are given in the accompanying table.

Product Assayed.	Per Cent. by Weight.	Assay, Lb. Per Ton.
Coarse sand	28.1	2.8
Fine sand	34.3	5.0
Slime	37.5	9.83

Calculating the total value from the parts gave an assay of 6.2 lb. per ton.

At this point in his investigations Mr. Hutchin realized that supplementary tests were necessary to ascertain the relative proportions of fixed tin to tin in free grains. Considering ultimate recovery, he saw that it was essential to know whether the whole, or, if not, what portion of the cassiterite was present, as (1) detached particles, (2) as adherent to the original gangue. One enters as a factor of crushing, the other as a factor of the ore dressing. With this in mind the Buss tailings were first investigated with the stamps crushing through 25-mesh screens. The results were as follows:

	No. 1 Table.	No. 2 Table.	No. 3 Table.
Tailings	6.0 lb.	5.0 lb.	2.8 lb.
Middlings	4.4 lb.	3.1 lb.	3.1 lb.

From screening tests of the first two these results were obtained:

	No. 1 Tail-ings.	No. 1 Mid-dlings.	No. 2 Tail-ings.	No. 2 Mid-dlings.	No. 3 Tail-ings.
Coarse	3.1	3.4	2.85	2.8	1.2
Fine	4.75	4.5	4.1	4.1	1.9
Slime	10.1	No slime.	10.6	No slime.	13.0

These results showed that the "coarse" fraction from No. 2 middlings (assay value 2.8) showed no evidence of the presence of grains of free cassiterite, while in the case of the "fine" fraction there was decided concentration presumably of free cassiterite. Of the 4.1 lb. assay value, 2.5 lb. was free for recovery by concentration, while 1.6 lb. was locked up in the gangue so as to require finer crushing.

The results of a test of Frue vanner tails show the proportion of slime to sand to be 4 to 1, and give the assay value of the whole calculated from the fractions

as 9.2 lb. These tests were so satisfactory that further work on the same line was followed out using samples of the tailings in bulk obtained from settling ponds.

SCREEN OPENING

Another point tested was the most advisable size of screen opening. Magnetic separation to reduce the amount of fine wolframite had been decided upon, so coarser crushing was tried using a 20-mesh instead of a 25-mesh screen. This gave results which at first seemed inconclusive, but pointed toward the idea that one size of mesh would give about the same results as the other. After considerable experimenting it appeared clearly that under normal conditions the change from 25- to 20-mesh battery screens was not accompanied by any appreciable increase in the loss as far as the bulk of the tailings was concerned, while the coarser crushing reduced the amount of slime and aided magnetic separation.

The work of the pulverizers and the conditions in working the coarse sands rejected from dressing the burnt concentrates on buddles called "burnt leavings," were next investigated. By treating some of these burnt leavings on a Buss table it was at once apparent that considerable tin was present as separate grains for the table gave concentrates assaying 6.6 per cent. cassiterite with middlings running only 1.7 per cent. This tin was, however, low in value on account of adherent particles of iron oxide. The pulverizers with their combined scouring and flouring action tended to make this tin available.

At first the burnt screenings were screened and vanned, but as previously vanning with rich tailings had been unsatisfactory another method was adopted. Sonstadt's solution of mercuric-potassium iodide of a specific gravity of 2.82 was used to separate the heavy constituents from the light, so that the nature of each could be investigated. In general this method is not as accurate as the vanning method and is besides more expensive. However, it is useful in cases where vanning is inapplicable and for a check method. In this case it certainly proved most useful. Ten grams of the coarse portion of the burnt leavings were cleaned of iron oxide with cold hydrochloric acid, washed and dried. This gave 6.502 grams cleaned product of which 1.524 grams were heavy and 5.04 grams light. The heavy assayed 723 lb. cassiterite per ton, the light only 5 lb. The fact that 15 per cent. of the material carried 723 lb. per ton is suggestive of the function of the pulverizers.

SLIMES AND HEIGHT OF DISCHARGE

Next in order to cut down the proportion of slimes the height of discharge in the stamp batteries was reduced from 7 to 3 in., and 20-mesh screens substituted

for 25-mesh ones. The percentage of coarse sand was 48; of fine, 52.

At the South Crofty mine the joint tailings from the mill are conveyed by a lead 3 ft. wide to ponds about 50 yd. away. From the latter part of the lead, which is on the sloping ground the tailings deposited were stripped and treated on Buss tables without pulverization. With daily stripping these concentrated only to about 2 per cent. cassiterite, although the proportion of mispickel was high.

RESULTS OF THE TESTS

All this investigation served to show the losses in the first stage of concentration as due either to insufficient crushing or to leakage on the concentrating tables. From the probable distribution of the tin as figured by the use of heavy solutions it appears that extremely fine crushing is necessary for a good recovery. On the other hand the change from 25-mesh screens to 20-mesh ones, as before noted, was accompanied by no higher losses. More experiment on this point of coarse crushing would be exceedingly instructive.

A comparison of the results obtained at three different mines using the same general milling practice on similar ore brings out more than anything else the nature of the ores treated as regards concentration. Mr. Hutchins finds the practice of pulverizing burnt leavings good, but finds no evidence to support such treatment of middlings from Buss tables. He takes only one head from his tables although the more recent plan is to take two, retreating the second heads from two or more tables on another one.

In general the tests show that coarse grains in the tailings carry higher cassiterite than fine ones, but the difference is not very apparent except in the case of rich tailings. The experiments with Sonstadt's solution indicate that a fairly large proportion of the cassiterite-carrying grains were of low specific gravity and even in the strippings from the leads where there was a certain proportion of similar grains presumably of higher specific gravity it is doubtful if their density was even high enough to class them as middlings. Coarse crushing was found to give coarse grains showing increased value, while too fine crushing gave slimes of high value.

The discovery of a new element is announced by M. Ogawa, of the University of Tokio, in the rare mineral thorine, in which it occurs as small yellow or red crystals, hard enough to scratch glass. These are found to be a double silicate of the new element and zirconium. The new element has been named nipporium; its symbol will be Np.; its atomic weight is probably 100.

Colorado State Geological Survey

A report of progress recently issued shows that field work in the past year includes four important areas: (1) The area about Hahn's Peak in Routt county, 110 square miles. (2) The tungsten field of Boulder county, 90 square miles. (3) The sedimentary formations flanking the foothills from the Wyoming line southward for 75 miles. (4) The Montezuma area in Summit county, 22 square miles.

ROCK MINERAL ANALYSES

In connection with the field work of the Survey about 50 complete chemical analyses and assays, and upward of 100 other determinations have been made. The State Survey will not do work which should go to private chemists and assayers, but only that demanded by its own reports.

TOPOGRAPHIC MAP OF COLORADO

The Hayden survey of the Territories, completed in 1878, made a topographic map of about two-thirds of the State. The King survey of the Fortieth Parallel included a narrow strip about two-thirds of the way across the southern border of the State. Of the area not covered by these two surveys, over one-half has been mapped in detail by the present United States Geological Survey. The other half has been mapped in less detail. The maps of the earlier surveys are available to but a very small number of people, and those of the present survey are contained in about 60 separate sheets.

The State Geological Survey has compiled a topographic map of the State on a scale of 1 in. to 8 miles, combining, so far as the scale would permit, the results of these various surveys, and including all the geological details usually found in a complete State map. This map will be used as a base for the revised geological map, and for maps showing the various mineral deposits, water resources and other economic features of the State. The map is almost ready for the engraver.

GEOLOGICAL MAP OF THE STATE

The only geological map covering the State is a small one, on a scale of 12 miles to the inch, published by the Hayden survey in 1879 and 1881. This is very general and incomplete. The larger Hayden atlas covers only two-thirds of the State. A vast amount of detailed geological work has been done in Colorado during the last 30 years, and has modified in many important ways, the conclusions reached by the Hayden geologists in their hurried survey. The results of this later work are published in perhaps 40 separate maps, many of which are not easily available.

The State Geological Survey is compiling a map, on the same scale as the topographic map, which shall bring together, so far as the scale will permit, the results of all geological work done in this State

up to the present time. The drafting is probably three-fourths done, and the explanatory sketch of the geology, to accompany the map, is also well under way.

A map showing the various metalliferous deposits of the State is approaching completion. Another showing the location of the coalfields is ready for the draftsman.

A bibliography of the geological literature of Colorado is well under way, and already contains over 5000 classified entries, together with reference letters indicating the important libraries of the State, in which the book, article or report may be found.

OTHER WORK COMMENCED

A report on the distribution, qualities and value of the clays of the State. (Prof. G. M. Butler, School of Mines.) The building stones and marbles of Colorado. (R. D. George and A. P. Poorman.) Cement materials, limestone and gypsum. (Direction of R. D. George.) Descriptive geology of the State in two bulletins: (1) General geology; (2) economic geology. (R. D. George and Professor Crawford.)

STAFF OF THE SURVEY

Prof. R. D. George, University of Colorado, State geologist; Prof. H. B. Patton, Colorado School of Mines, geologist; Dr. James Underhill, mining engineer, Idaho Springs, geologist; Prof. G. M. Butler, Colorado School of Mines, geologist; Prof. R. D. Crawford, University of Colorado, geologist; Prof. C. E. Smith, Colorado School of Mines, geologist; Prof. Junius Henderson, University of Colorado, paleontologist; Prof. J. B. Ekeley, University of Colorado, chemist; C. C. Williams, A. P. Poorman, draftsmen; B. H. Jackson, W. M. Lewis, T. D. Benjowsky, field assistants; R. M. Butters, G. D. Kendall, H. Whitaker, F. H. Millard, chemical work of various kinds.

The vagaries of boreholes have recently had a fresh illustration, says the *Kalgoorlie* correspondent of the *Mining Journal*. Some years ago a hole was put down at an angle from the surface of the Central Boulder lease, and at a depth of 1500 ft. a rich vein of telluride ore was cut, in what was then thought to be the Central Boulder ground. A subsequent survey of the hole showed that the drill had diverted, and it was then announced that the telluride was in the Oroya South lease, and not in the Central Boulder block. Now comes the news that the bore hole has been struck at 1200 ft. in the Kalgoorlie lease, which lies east of the Oroya South block, and which is now owned by the Oroya Brown Hill Company.

A new tin find is reported from the Stannary Hills district, Queensland (*Aust. Min. Stand.*, Dec. 16, 1908), the discovery being near the Lass o' Gowrie mine.

Sinking in Wet Ground by Injecting Concrete

After Sealing Fractures in Surrounding Rock by Injections from Churn-drill Holes, the Shafts Were Easily Sunk through Very Wet Ground

BY JULES LOMBOIS*

The Compagnie des Mines de Béthune has had to sink three shafts through watery ground; in each instance a cementing process was employed. The shafts were sunk in successive years, so the experience gained in each was brought to bear on the next. Consequently a record of our operations ought to be instructive to other engineers engaged in the same kind of work.

In the vicinity of shafts 11 and 11 bis, the coal seam is covered by 150.4 m. of Cretaceous sediments, composed of the following strata: Fissured white limestone, 46.2 m.; hard sandstone, 0.8 m.; gray phosphatic limestone, 6.3 m.; bluish marly limestone, "bleus," 32.7 m.; greenish marly limestone, "dièviens," 32.5 m.; slightly argillaceous white limestone, 22.5 m.; conglomerate, 3.4 m.; shales, 6 m.

The fissured white limestone is the source of the most of the water. The gray limestone yields only a little. The blue limestone is only slightly fissured, but occasionally affords a strong flow of water. The green and the lower white limestones are both compact. The problem was thus to solidify, by cementation, the white, the gray and the blue limestones by bore holes regularly distributed around the circumference of the proposed shaft.

I shall first outline the mode of operation at shaft No. 11, in 1904, and at shaft No. 11 bis, in 1905, pointing out such improvements as occurred, and shall then describe, in some detail, the sinking of shaft No. 7 bis, in 1906 and 1907.

SHAFT No. 11

This shaft was first dug with a diameter of 5.2 meters to a depth of 4.2 meters. Four holes were then bored, equidistant from each other, and at 2.36 m. from the center. On account of the long time required to sink holes and cement them in the usual way, by successive advances, it was decided to inject cement into two of the holes while they were being bored. Two of the holes, of 300 mm. diameter, were therefore bored and injected with cement in alternate stages, while in the other two, of 180 mm. diameter, boring and injecting went on at the same time. A churn drill was used for all.

The cement mortar was mixed by hand, using ordinary portland cement, and was

then injected into the holes, the tops of which were closed by iron pipes with the necessary connections, by a Burton pump, affording a maximum pressure of 4 kg. per sq.c. The holes were lost twice owing to the premature setting of the mortar. Operations lasted a little over two months, during which time 1776 sacks of cement, weighing 50 kg., were injected; of this, 70 per cent. was absorbed by the holes bored in the ordinary way, and 30 per cent. by the holes which were injected during boring.

per cent. of clay, all traces of cementation had disappeared. The poor success in this rock was due to chips of clayey material which would lodge in the crevices and resist the injection of cement even under a pressure of 10 kg. per square centimeter.

SHAFT No. 11 Bis

This shaft is at a distance of 48 m. from No. 11. The principal improvements over the operation as conducted at the first shaft were the following:

After the shaft had been sunk and lined with masonry to a depth of 14 m., with an inside diameter of 5.2 m., the four holes were drilled on the outside of the shaft, equidistant from each other and at a distance of 4.07 m. from the center. The holes were all bored and injected alternately, which permitted the application of the full force of the pump. In the white and gray limestone, the holes were bored with a churn drill, but in the blue marl a special auger was used which prevented the choking of the fissures by chips of rock. Three applications of the auger were sufficient to gain 1.5 m. depth, which was adopted as the advance for each stage of drilling and cementing.

Instead of the ordinary portland cement used at shaft No. 11, a specially fine cement was employed, of which only 16 per cent. would not pass a screen having 170 meshes per inch. Mixing was still done by hand.

In the white limestone strata above the water level, the injections were made without a pump, all necessary pressure being obtained by placing the mixing box on a platform at a height of 4.75 m. above the ground. The object of this was to form, for the upper 45 m., a solid mass of concrete which would withstand the pump pressures required for injecting the lower, water-bearing strata. In spite of this precaution, when the pump pressure was applied openings appeared between the drill holes and the bottom of the 14-meter pit, and it was never possible to hold a pressure of more than 10 kg. in the first two holes. In order to inject the blue limestone thoroughly, the third and fourth holes were cased with pipe, having 3-mm. walls, down to the top of that stratum. Even then two leaks occurred during the injecting of these holes, which had to be repaired by using a 35-per cent. mixture of cement.

The total amount of cement used in

GENERAL PLAN OF INSTALLATION

As the rock was exposed by subsequent sinking, the following facts were noted: In the white and gray limestones, the fissures were perfectly filled but the seams of cement were very variable, being compact and hard in some places, but in others soft and yellowish, imperfectly set, and without strength. These poor results were attributable to the coarseness of the original cement, which permitted separation of its coarse and fine particles, and to incomplete mixing of the mortar. In the blue limestone, solidification was fairly complete in the upper portions, which were only slightly argillaceous, but below this, where the marls contained around 18

*NOTE.—Abstracted from *Bulletin de la Société de l'Industrie Minière*, Tome IX, No. 4.

*Chief engineer, Compagnie des Mines de Béthune.

this shaft was 4981 sacks (50 kg.). By using the alternating method, and a Weise & Monsky vertical, compound pump capable of high pressures, it was possible to force 3997 sacks of cement into the water-bearing strata, instead of only 761 sacks, as at shaft No. 11.

The results of this method were very satisfactory. Almost all the fissures were found to be well filled with solid seams of cement of grayish black color and homogeneous composition. Only two seams contained yellowish, soft cement and these did not yield much water. At a depth of 88 meters only 5 cu.m. of water had to be raised per 24 hours, as against 145 cu.m. at the same depth in shaft No. 11. Shaft No. 11 *bis* was begun at a depth of 14.9 m. on May 14, and finished completely to 94.92 m. by July 13, 1906. The average daily advances to this depth were thus: For sinking, 3.47 m.; for lining, 2.18 m.; for sinking and lining, 1.34 m. per 24 hours.

MIXING AND PUMPING PLANT

SHAFT No. 7 *Bis*

The measures to be perforated at this shaft have a total thickness of 142.5 m., consisting of the same strata as at No. 11 and having about the same relative thicknesses, except that the bluish, marly limestone is somewhat thicker and the greenish limestone much thinner than at the former shaft.

The water level varies from 17 to 29 m. At No. 7 shaft, sunk some years earlier, as much as 1700 cu.m. of water had been pumped, per day, from a depth of 66.5 m. Furthermore, two important seams of coal had already been completely extracted from this vicinity, which gave reason to fear that the overlying strata would be found to be badly fissured. For these reasons it was thought wise to sink six injection holes, instead of four.

A preliminary shaft was first dug to a depth of 3.5 m. in order to facilitate operations and to afford a fairly solid stratum for inserting the injection pipes. The pit

was lined with masonry to an inside diameter of 8 m. The six holes, evenly spaced around a circumference with 3.65-m. radius, were then bored and injected in successive stages. As at No. 11, each hole was made with a churn drill in the hard measures and with a rotary, auger drill in the soft argillaceous strata.

In order to guard against leakage around the upper ends of the holes, and to insure the application of the full pump pressure, a little shaft, 5 m. deep and 1.30 m. diameter, was dug at the spot to be occupied by each hole; the lining pipe was then inserted and the space around it was carefully filled with well rammed concrete, with frequent applications of cement grouting. The lining pipe was of steel, 8 mm. thick and with an inside diameter of 300 mm. Its upper end had a cast-iron head, to which the necessary pipe connections were made. A 50-mm. pipe, fitted with a pressure gage and a stop cock, entered the side of the casing

the second of 245 mm. diameter, were then used to scrape the walls of the hole so as to remove any cuttings from the crevices. The drill stem, formed of steel tubes 5 m. long and of 66 mm. interior diameter, was used for injecting the cement. The force for operating the reamers was furnished by a 12-h.p. portable engine. The time required for advancing 3 m. by this method was a little over 13 hours; toward the end of the operation it became possible to bore and inject 3.10 m. per day.

To afford a more perfect mixing of the mortar, as well as to save in labor, a mechanical mixer was installed. It consisted of a 150-liter cask, carrying a vertical shaft to which four paddles were fastened; the shaft making 60 r.p.m. The cement and water were thrown in at the top, and the mixture ran off to the pumps through suction pipes which left the cask at 40 cm. from the bottom, that is, a little above the level of the suction valves of the pumps.

The pumps were of the Weise & Monsky, compound type, with flywheel; the two plungers were of 90 mm. diameter and 200 mm. stroke, yielding, at 75 r.p.m., a flow of 9.5 cu.m. per hour; the suction was 50 mm., and the discharge 40 mm. in diameter. To avoid the corrosive action of the cement, the bronze valves were replaced by steel balls, 105 mm. diameter, weighing 4.52 kg. apiece. The force with which these balls fell upon the bronze seats of the valves kept the latter free from adhesions and maintained a smooth and regular operation. These precautions permitted the passing of 2500 sacks of cement without any difficulty, whereas, at No. 11 *bis*, the valves had to be changed after every five hours, or for every 60 to 80 sacks.

All the strata from the bottom of the casing pipe, at 8.5 m. below surface, down to the bluish marls, were injected in successive 5-m. stages, with the whole pressure of the pump, 20 to 25 kg. per sq.c. The injection pipe was formed of sections 5.4 m. long, having an inside diameter of 40 mm., and connected by outside bronze couplings. The relatively small section of the pipe compelled a rapid circulation of the liquid in the pipe and around the bottom, whereby any tendency of the mortar to separate was overcome. At the surface, the end of the pipe was connected to the pump by a strong rubber hose which permitted a certain amount of vibratory and sliding motion of the pipe, which was given it to prevent accumulations of cement. The procedure was as follows:

After the injection pipe had been lowered to within 1 m. of the bottom of the hole, the head gear of the casing pipe was bolted together. Clear water was then put through the pump, the cock in the return pipe at the top of the casing

pipe just below its head. During the preliminary washing of the hole, which followed each drilling operation, this pipe carried off the muddy water; as soon as the water came up clear, the pipe was connected to the cement mixer in order to return to it the excess of cement toward the end of the injecting process.

For boring through the limestones, the contractor at first tried a drill which was too light and resulted in the loss of two holes; after this had been replaced with a heavier drill, on the Hulster, free-falling system, it was possible to make an injection of cement and bore the hole 5 m. deeper in six hours. For boring in the argillaceous measures, a new auger was made, 2.50 m. long, 175 mm. diameter, with turns pitched 370 mm. apart. The adhesion of the cuttings in marl was sufficient to bring them to the surface, attached to the auger. Three applications of the auger would deepen the hole 3 m. Two reamers, the first of 225 mm. and

being left open; after about an hour the return water would become clear. The cock was then closed and the pump driven to full capacity in order to force any remaining debris as far back as possible into the crevices of the rock; this process lasted about half an hour. Then, without changing any other conditions, cement was added gradually, to form about 5 per cent. by weight of the mixture; after an hour of this, the percentage of cement was raised to 10, if no increase had been noted in the pressure in the hole. As the cement deposited in the fissures of the rock, it became necessary to increase the pressure at the pump. Finally, as the fissures became more thoroughly plugged, in order to avoid too great pressure and the stopping of the pump, the cock in the return pipe had to be opened little by little, the excess of grouting being carried back to the mixer. Toward the end, the con-

with a pipe slightly smaller than the upper casing pipe. Occasionally, also, the cement injected in one hole would reach and flow into another hole which had been temporarily abandoned upon reaching the marls. To avoid this, whenever work was suspended in any hole, it was filled with sand; the sand could afterward be removed easily by a water jet.

After having injected all six holes down to the marls, these latter were then treated in exactly the same way. The amount of cement used in the limestones was 1514 sacks, and in the marls, 1594 sacks. The time occupied was 10 months and 10 days, including Sundays and holidays when no work was done. This rather excessive

and lining. This excellent speed was mainly due to the freedom from water in the shaft.

The main advantages of this method are its cheapness, in that only a small and inexpensive equipment is required and the cost of labor and material is small; and its practical advantages, in that water is almost completely shut out, the erection of masonry linings is made more secure, the solid wall of concrete makes a lining almost unnecessary, and finally any repairs to the lining are more easily executed.

Phelps, Dodge & Co.

Phelps, Dodge & Company, Inc., reports to the Stock Exchange assets and liabilities as of Jan. 31, 1909, as follows:

ASSETS.	
Copper Queen Consolidated Mining Company stock, 199,516 shares at \$135	\$26,934,660
Moctezuma Copper Company stock, 26,000 shares at \$307.3	8,000,000
Detroit Copper Mining Company of Arizona stock, 40,000 shares at \$150	6,000,000
Stag Canon Fuel Company stock, 5000 shares at \$800	4,000,000

Plant renewal	1,440,000
Balance, surplus, Dec. 31, 1908.	\$8,896,342
Total.	\$13,533,043

The income accounts of the Moctezuma Copper Company and the Detroit Copper Company for the year ended Dec. 31, 1907, follow:

	Moctezuma.	Detroit.
Net income for year	\$833,236	\$814,874
Previous surplus	1,182,769	739,621
Total surplus	\$2,016,006	\$1,554,495
Dividends	130,000	*200,000
Profit and loss surplus.	\$1,886,006	\$1,354,495

*Includes \$120,000 plant renewal fund, and \$80,000 dividends.

The tube mills used in Australia are smaller than those generally used in the United States, Mexico and South Africa.

AUGER AND REAMERS

SECTION THROUGH ONE BORE-HOLE

sumption of cement was reduced, and the pipe was kept in active motion. The operation was finished when it became necessary to keep the return pipe entirely open to maintain the operation of the pump. The pump and the pipes were then cleaned by a current of water, after which the pipe was withdrawn and the hole was left eight hours to allow the cement to set.

It was often noted that the pressure in the pipe would suddenly drop. This event was due either to the dislodging of a partially solidified cement plug, or to the opening of a channel connecting the hole with the surface. The latter case occurred frequently when the upper part of the section of rock to be cemented was soft. Crevices of this sort were stopped by injecting a thick mortar, 30 to 35 per cent. cement, under low pressure. Another way was to line the hole, down to some solid stratum generally at 20 m.,

length of time was due to the accidents and losses of holes arising from the inexperience of the workmen. Before operations were over, it was possible to sink and inject 5 m. in the limestones and 3 m. in the marls per day.

The holes were bored by a contractor; at the end of each advance, the borers would assist the company's men in making the injections. In addition to the contractor's men, the entire force included a foreman, a fireman, and two laborers.

The sinking of the shaft then began, and was completed in five stages. The strata were found so thoroughly solidified that explosives had to be used. A number of crevices, from 1 mm. to 11 cm. wide, were found to be filled completely. At a depth of 87 m. the total seepage was only 1.66 cu. m. per hour. Down to the 395-m. level, the average daily advances were 3.05 m. for sinking; 4.71 m. for lining; and 1.85 m. per day for both sinking

A Method for Setting Timber in Inclined Shafts

By C. W. McDougall*

The method of setting timbers in an inclined shaft, which is described in this article, has been found to be very good after a test under various conditions, extending over two years.

The apparatus used consists of a special try-square, a carpenter's spirit level, a wooden straight-edge, 10 ft. long, and a transit. The try-square is made of wood according to dimensions shown in Fig. 1; the target on it is an ordinary level target with alternate red and white quadrants. This target slides on a piece of hardwood attached to the front of the try-square.

The transit is mounted on a bracket which can be attached to the sleepers in the shaft, thus doing away with the difficulties of a tripod set up, especially in a steep shaft where there is danger of the instrument's falling. The bracket also gives

height of the instrument above the face of the sleepers when set on the proper dip, must not be moved. The sleeper that is being set is then moved either up or down until the center of the target coincides with the horizontal cross wire of the instrument. The sleeper is kept in a level position horizontally by means of a long straight-edge and a carpenter's level.

After the sleeper has been set in the proper position and secured, the balance of the set is trued, and the work of placing the next set begins. In truing the set, and in setting the sleeper, or footwall plate, care should be taken to have the set placed normal to the dip of the shaft, or canted by the same amount as was the original set, otherwise the reading on the target will be wrong in a manner similar to the reading on a level rod when the rod is not held in a perpendicular position.

Care should also be taken to have the center line of the try-square on the line of collimation of the transit. The transit and try-square need to be used only to set sleepers about 50 ft. apart so as to

previously set and on the center line, and the sleeper to be set is brought to the proper elevation, which will be indicated by the coinciding of the plumb line on the straight-edge with the mark previously made for a guide. Then the sleeper is brought to a horizontal position by using the carpenter's level in conjunction with the transit.

In truing the sets, it was found very convenient to have a large square made in order to test the angle of 90 deg., formed by the end plates and dividers with the footwall plate, or sleeper. When the intermediate sleepers had been set with the dip straight-edge, using a proper amount of care, the greatest error found

FIG. 1. TRY-SQUARE

FIG. 2. DIP LEVEL

more room to the instrument man, while making observations.

METHOD OF SETTING "CHECK" SLEEPERS

The instrument is set up in the shaft on the bracket over a point on the center line of the shaft, or on some line parallel to the center line, and sights are taken to place the line of collimation parallel to the center line of the shaft. Then, after the center line of the transit has been set at the proper dip by means of the vertical arc, the instrument man is ready to proceed.

The try-square is placed in the center line on a sleeper that has previously been set, and the target moved up or down until the horizontal cross wire in the telescope coincides with the horizontal center mark on the target. The target is then clamped in position, and the try-square is moved to the sleeper that is to be set. The try-square is placed on the center line and a sight is taken at the target which, since its position represents the

check up the work and keep the shaft in line.

The usual time required to set a sleeper, under ordinary conditions, is 30 to 45 min., divided as follows: Setting up instrument, about 15 min.; setting sleeper depending on the distance it must be moved and whether wedges or jacks are used in moving the timber, 15 to 30 minutes.

METHOD OF SETTING INTERMEDIATE SLEEPERS

To set the intermediate sleepers, a dip level such as is shown in Fig. 2 is used in conjunction with the straight-edge and carpenter's level previously mentioned.

The proper dip angle is laid off by means of natural sines and cosines on the bars forming the square mounted on the straight-edge, the two legs of the square being the sine and cosine, respectively, of the dip angle. The accuracy of the triangle formed by the square and straight-edge is proved by calculating the length of the hypotenuse of the triangle.

To use the dip straight-edge, one end is placed on two sleepers that have been

by checking with the transit was not more than one-half an inch, and this may readily be accounted for by the fact that ordinary squared timbers are seldom exactly true, either in section or longitudinally, and also by the possibility of a slipping of the wedges that held the sets in place.

According to B. I. Collins in a paper before the Chemical, Metallurgical and Mining Society of South Africa, the ultimate mining future of the Rhodesian goldfields lies in the development of the large low-grade bodies of impregnated ironstone, schist, and conglomerate, rather than in the small and non-persistent quartz veins. At present most of the mines work the latter class of deposit and are operated by small workers with rather insufficient equipment. These small operators cannot afford to extend their operations to the big low-grade orebodies, since there the values are irregularly distributed, and extensive prospecting is required to ascertain accurately their value.

*Chief engineer, Hancock Consolidated Mining Company, Hancock, Mich.

The Stephens Climax Imperial Hammer Drill

BY EUSTACE M. WESTON*

An English firm, R. Stephens & Son, of Cornwall, has designed a hammer drill built as largely as possible on the lines of a piston drill and having every part readily accessible for inspection; this is the latest type of hammer drill especially designed to meet the conditions on the Rand. In designing this drill, it was determined to construct a machine of the maximum power possible within the limiting weight of 100 lb. laid down as the maximum weight allowed for machines competing for the £4000 prize on the stoping-drill contest. In this drill air consumption has not been considered an important item. The consumption is given as being about three-fifths that of a 3¼-in. drill. It would therefore be about equal to that of a 2¾-in. drill or from 70 to 80 cu.ft. per min. with air at a pressure of 80 lb. per sq.in. The machine complete weighs 95 lb.—20 lb. more than the Gordon drill. With an air pressure of 75 lb. per sq.in., the number of strokes per minute is said to be about 700.

The length of stroke is 5 in.; the diameter of cylinder is 1¾ in. and the weight of the hammer is 6½ lb. It will be seen that this drill is more powerful than any American stoping drill except the Leyner model 6 machine. The general construction of the machine which includes some novel features can be seen from the accompanying sketch sections. Fig. 1 is a longitudinal section; Fig. 2 is a transverse section. The half-tone illustration shows the machine set up for work and also two drill bits. In Fig. 1, *A* is the anvil block. It is about 9 in. long by 1¾ in. diameter; it weighs 8 to 10 lb. The anvil block and pinion wheel *G* are made in one piece and from special steel. This pinion wheel prevents the anvil block's being forced back into the cylinder. It will be noted that it is provided with a taper recess for a taper chuck *C*, having a water-feed channel *WFC* through it. This channel communicates with a brass water-feed ring *W*, which is surrounded by buffer rings made water-tight by packing *PK*. Water is led from the two-way throttle valve, shown in the half-tone illustration, through the channel *WFC*, along the side of cylinder and front head to the brass water-ring *W*.

The amount of water used is regulated by means of two cocks—one on the hose; the other, a brass screwhead, on the machine itself. No air passes down the hollow steel with the water. Any water leaking past the ring toward the cylinder drains away through holes *ESW*.

The pinion wheel *S* gears with the spur wheel *G*; this is rotated by the crank

handles *RH* to which it is connected by a telescopic rod. The rotation is thus geared and positive being operated by hand similarly to the way that rotation is effected in the Leyner Rock Terrier drill, which this machine resembles somewhat. *GF* is the main cylinder casting and slides in the flat cradle *K*. It is bored out for two cylinders; *AFC* is the air-feed cylinder, *AFP* is the air-feed piston attached to cradle *K*. The air admitted to the machine enters the air-feed cylinder and feeds the machine forward before it enters the main cylinder; as soon as the air is turned off, *AFC* is opened so as to exhaust. The drill must be slid back by hand, but as the drill is light and the holes seldom vertical this can be easily done. Another forward feed is gained (see Fig. 2) by sliding the cradle forward in the clamp. One side of the cradle has teeth on it; when the clamp bolt is loosened the cradle slides easily forward and is then securely fastened again by the

end of the valve chest alternately in connection with the atmosphere through *AV* and *AV'*, the recess in piston *R*, and the two exhaust ports *EX* and *EX'* in the walls of the cylinder. In Fig. 1 the piston *P* has finished its stroke, and *AV'* is open to exhaust so the valve will be thrown over for the return stroke. The valve could be set to cut off and use air expansively on either front or return stroke. This is done in the large piston drill made by the same company, but I do not know whether or not this is done in the hammer drill. It will be noted that the valve motion is simple and that the valve can be easily inspected. The machine is held together by side rods *SR*. The packing in the front head can be readily taken out and changed if it becomes worn.

The novel points about the design are: First, the compact air feed which allows the machine's being kept short and so made similar in shape to a piston drill,

STEPHENS CLIMAX IMPERIAL HAMMER DRILL

toothed clamp when it is tightened. With these two feeds, a total advance of 28 in. is gained; this is ample in the hard ground here, where hammer-drill bits are generally blunted after boring 12 or 15 inches.

The main cylinder *X* is 1¾ in. in diameter. The piston *P* is of shape shown. *PO* and *PO'* are the air ports; *VB* is the valve chest; *V* is a piston valve, and *AV* and *AV'* are two leather auxiliary valves. They are conical leather plugs which control the exhaust from the valve ends. They are pushed down so as to always make an air-tight sliding fit with the piston *P*, no matter how worn the cylinder may be. Thus the valve movement is kept regular.

The valve action can be seen from Fig. 1. The air is allowed to leak past each end of the valve from the live-air chamber in the center of the air chest in sufficient quantity to throw the valve over when the other end is open to exhaust. The movements of the piston *P* place each

and yet without a feed screw; second, the great weight of the anvil block—this would seem at first to be a great mistake in design; third, the adoption of the taper chuck attachment. This makes the anvil block simply a part of the drill bit as it fastens immediately to the drill shank. This construction seems to me to reduce vibration greatly and to be the reason why the makers say that they have had no trouble with breakages of this part, in spite of the fact that it has holes bored in it and of the difficulty that every maker finds in tempering anvil blocks with holes in them. The anvil block is always "up to its work" and there is never any lost motion between it and the drill owing to rebound. Of course, a somewhat harder blow has to be struck to make up for the greater inertia of the combined boring tool, but the advantage gained seems to outweigh this.

The machine does not seem to be very economical in air, for the cylinder volume

*Mining engineer, Mbabane, Swaziland.

on the return stroke is large, owing to the fact that there is no piston rod to take up this space. The length of the machine over all is 2 ft. 10 inches.

I witnessed a trial of this machine on a block of granite similar to that used in the South African mines stope-drill competition. The hole drilled was horizontal, the water pressure about 10 lb. and the air pressure 80 lb. per sq.in. The machine bored about 12 in. with a 1¼-in. double-chisel bit, 13 in. with a 1½-in. chisel bit and 14 in. with a 1-in. chisel bit; or a total of 39 in., in a total time of 9 min. 22 sec., or an actual drilling time of 8 min. 48 sec. The average speed was 4.23 in. per minute.

In another trial 3½ in. was bored in 12 min. 15 sec.; the bits were chipped and well blended. It will be noted that the width of the bits used was less than that of those used in the South African mines trials; had the drilling been done with 1½, 1¼- and 1½-in. bits, the rate of drilling would be slower. In the Government trials in 1909 the finishing gage of the holes at a depth of 48 in. must be 15/16 in. This means that holes will have to be

Cumberland Ely Copper Company

The report of the Cumberland Ely Copper Company, Feb. 5, 1909, shows that for the year ending Nov. 30, 1908, \$1,190,521, was expended in development work, and its proportion of the cost of construction of the Steptoe Valley Smelting and Mining Company's plant.

During the year a four-compartment shaft was sunk and is now in service. A large electric hoisting plant, with self-dumping skips, was installed and has proved most satisfactory. Ore bins were constructed and the requisite number of buildings for the accommodation of employees completed, together with an extensive pipe line which furnishes an abundant supply of water for all purposes at the mine.

The success of the caving system of mining was fully demonstrated, and is producing satisfactory results. Up to Feb. 1, 1909, 198,611 dry tons of ore were mined, of which 177,589 tons were milled, showing an average copper content of 3.1 per cent. The production at the present time is at the rate of 1200 tons per

Pennsylvania Railroad's New Coke Cars

In an effort to provide shippers of coke with an improved car, which can be loaded and unloaded in the shortest possible time, the Pennsylvania lines west of Pittsburg have specified that of the recent order for 2200 new cars, 1000 shall be all-steel cars of new design and of greater capacity than any coke cars hitherto built for regular service.

The main novelty in these cars will consist of four hoppers, with eight openings in the bottom of the car, making the car

FIG. 1
STEPHENS CLIMAX IMPERIAL HAMMER DRILL

FIG. 2

started with 1¾- or 1½-in. bits. I have already shown what effect this has on boring speed. This machine, I should say, has a speed of boring equal to that of a 2¼-in. piston drill having a 6-in. stroke and boring with bits of the same size; but the Stephens is, of course, lighter, smaller and more easily handled than the piston drill, while with a double-pointed wedge key the drill bits are changed very rapidly indeed. The shape of drill bits used is shown in the half-tone illustration. The shank ring is necessary for taking out the bits by means of the key.

An increase from 3,500,000 gal. of the oil of coal tar, or creosote, imported into the city of New York in 1904, to an amount estimated to be almost 25,000,000 gal. in 1908, is one of the indications pointing to the progress of the nation-wide movement for the conservation of forest resources. It is creosote which the Government and scores of corporations and private wood users have found to be one of the most satisfactory preservatives of railroad ties, mine props, telephone and telegraph poles, fence posts, and for timbers used for commercial purposes.

day. The railroad to the concentrating and smelting plant at McGill has been in operation for some time, and is so constructed and equipped that it can readily meet all demands made upon it for the transportation of ore and other traffic.

The average extraction was 71.19 per cent., and during December and January, 73.33 and 76.12 per cent., respectively.

The accompanying table shows comparative assets at the end of Nov. 30, 1907 and 1908.

COMPARATIVE STATEMENT OF ASSETS AND LIABILITIES.

	November 30, 1907.	1908.
ASSETS.		
Property account:		
Cost of mine, including expenditures for construction and development.....	\$4,371,017.33	\$4,676,538.88
Investment account:		
Cost of capital stock of other companies.....	3,315,000 00	4,100,000 00
Material on hand.....		36,222.74
Metals:		
Value of metals refined and in process, less advances on same.....		353,489.77
Cash and cash items.....	1,077,243.47	37,783.01
Total.....	\$8,763,260 80	\$9,204,034 40

practically self-clearing. With the doors all open, there will be an open area of 84 sq.ft. This will greatly facilitate unloading. It has been found that three somewhat smaller cars could be unloaded by three men in 15 minutes from the time they were placed on the trestle until the engine moved them away. From the time the drop doors were opened until the coke ran out of the car required 1 min. and 45 sec. The four-hopper car is expected to do even better.

To facilitate loading, it is planned that the old-fashioned coke racks shall be left off these cars, and the sides of the cars will not be as high as in previous designs. This loss is repaired in the greater length, 42 ft., of the new cars. The drop doors are to be provided with operating gear of special design. The total capacity of each of the new cars is 2704 cu.ft., providing for a load of 100,000 pounds.

In breaking ore the face of the stope should be carried so that the greatest advantage can be taken of any weakness in the ore such as schistosity, fracture planes, and jointings.

The United States Steel Corporation

The Returns of the Great Corporation for a Year of Industrial Depression.
A Loss of \$250,000,000 in Gross Receipts, but Dividends Are Continued

BY FREDERICK HOBART

The report of the United States Steel Corporation, covering the calendar year 1908 gives, as usual, a comprehensive statement of the business of the company. The figures are so large and the transactions covered so varied and extensive, that proper analysis of the report is a work of some time. It illustrates well the great reaction which affected the iron and steel trades in the past year. Thus the gross sales of the company, as compared with 1907, decreased \$274,706,928, or 36.3 per cent.; while the net earnings, after deducting all general and operating expenses, depreciation and renewal funds, were diminished by \$69,116,963, or 42.9 per cent. Dividends on the preferred and common stock were continued in 1908, but the appropriations for additions to property and new construction—which were \$54,000,000 in 1907, and the same amount in 1906—were omitted entirely last year. The surplus over all charges, from which appropriations were made, shows a decrease last year of \$58,836,850, or 56.3 per cent. This proportion of decrease was naturally much greater than that in the net earnings, since the charges on the debt were not diminished, but showed some increase, chiefly due to the issue in 1907 of bonds for the purchase of the Tennessee Coal, Iron and Railroad Company stock.

THE GENERAL BALANCE SHEET

The condensed balance sheet, reduced to its lowest possible terms, may be stated as follows:

LIABILITIES.	
Capital stock, preferred	\$360,281,100
Capital stock, common	508,302,500
Capital stock, subsidiary companies, not owned	640,302
Total stock liabilities	\$869,223,902
Bonded and debenture debts	593,231,209
Mortgages and purchase obligations	4,161,981
Current liabilities	43,031,854
Sinking, depre. and res. funds	64,879,360
Bond sinking funds	38,074,012
Undivided surplus	133,415,214
Total liabilities	\$1,746,017,532
ASSETS.	
Property accounts	\$1,474,142,655
Deferred charges	6,306,666
Outside investments	3,083,000
Sinking and reserve fund assets	23,263,033
Current assets	239,222,176
Total assets	\$1,746,017,532

The stock accounts were unchanged last year; the bonded debt showed a net decrease of \$7,454,957. The undivided surplus—\$133,215,414—represents the working capital. The inventory valuation of materials on hand, included in current assets, amounted to \$136,188,874 in the close of 1907, and \$143,170,629 in 1908.

This condensed balance sheet exhibits the combined assets and liabilities of the United States Steel Corporation and of the several subsidiary companies, based on the valuations at which the stocks of the subsidiary companies and the Carnegie company bonds were acquired by the Steel Corporation; but liabilities from one company to another are omitted from both liabilities and assets. The outstanding capital stocks of subsidiary companies which are not held by the United States Steel Corporation show a net decrease during the year of \$121,507. This results from the acquirement during the year by the corporation of an additional \$158,405. par value, of Tennessee Coal, Iron and Railroad Company's stock, less the issue to outside holders of \$36,897 of that company's stock purchased by them under subscriptions made prior to the date at which a controlling interest in the Tennessee company's stock was acquired by the corporation.

CAPITAL EXPENDITURES

The expenditures made during the year by all companies and properly chargeable to capital account, for the acquisition of additional property and construction, less credits for property sold, equalled \$49,422,697. All of the above expenditures comprehend only actual additions and extensions to the plants and properties. The capital expenditures are classified by property groups as follows:

Gary, Indiana, plant	\$18,733,841
Other properties; exclusive of Tennessee:	
Manufacturing	14,610,517
Coal and coke	1,938,402
Iron ore	3,103,966
Transportation	7,238,627
Miscellaneous	336,351
Tennessee Co. properties	3,460,993
Total for the year 1908.	\$49,422,697

In addition to the foregoing amount there was expended the gross sum of \$7,453,158 for stripping the overburden from orebodies preliminary to mining ore from open pits, for additional logging equipment, etc. Against this charge was credited \$1,813,611 for expenses of foregoing character absorbed in operating expenses for 1908 for mining ore and timber logged, leaving a net increase during the year in the amount invested in stripping outlays and logging equipment of \$5,639,547. The total investment at Dec. 31, 1908, in these operations and carried in property account equals \$15,936,929, all of which will be absorbed in operating expenses when respectively the ore thus uncovered is removed and timber is cut.

Since April 1, 1901 (the date of organization), to Jan. 1, 1909, the amount expended by all companies for additional property and construction equalled a total of \$255,497,087.

INCOME ACCOUNT

The statements of accounts, statistics, etc., presented in this report comprehend, unless otherwise specifically stated, the combined results for the United States Steel Corporation and all of the subsidiary companies, including the Tennessee Coal, Iron and Railroad Company. A condensed statement of the income account for the year is as follows:

Net earnings for the year	\$91,847,711
Sinking funds, subsidiary cos.	\$1,588,071
Depreciation funds	3,844,214
Replacement funds	11,532,807
Interest on Steel Corp. bonds	23,862,647
Sinking fund Steel Corp. bonds	5,385,203
Total charges	\$46,213,032
Net balance	\$45,634,679
Add adjustment of accounts	94,035
Total surplus	\$45,728,714
Dividends, preferred, 7%	\$25,219,677
Dividends, common, 2%	10,166,050
Total dividends	\$35,385,727
Undivided earnings	\$10,342,987

No appropriations for new construction were made during the year. Such appropriations amounted to \$54,000,000 in 1907.

A comparative statement of all receipts and disbursements for two years is given in the following table:

	1907.	1908.
Gross sales	\$757,014,768	\$482,307,840
Interest on investments	9,748,951	5,786,885
Total receipts	\$766,763,719	\$488,094,725
Operating expenses	\$564,166,767	\$367,735,102
General expenses	25,395,379	21,001,037
Subsidiary cos.' accounts	16,236,889	7,510,875
Total expenses	\$605,799,045	\$396,247,014
Net earnings	\$160,964,674	\$91,847,711
Interest and sinking funds	\$27,719,744	\$29,153,815
Depreciation and replacements	28,679,366	16,965,182
Total charges	\$56,399,110	\$46,118,997
Surplus	\$104,565,564	\$45,728,714
Dividends	\$35,385,727	\$35,385,727
New construction	54,000,000	
Total appropriations	\$89,385,727	\$35,385,727
Undivided profits	\$15,179,837	\$10,342,987

The gross sales represent the aggregate value of the commercial transactions conducted by the respective companies, and include sales made between the subsidiary

companies and the gross receipts of the transportation companies for services rendered both to subsidiary companies and the public. The earnings resulting represent the combined profits accruing to the several corporate interests on the respective sales and services rendered, each of which is in itself a complete commercial transaction.

PRODUCTION

The production of the several subsidiary properties for the year 1908, in comparison with the results for the year 1907, is shown in the subjoined table. In order to make the comparison upon relatively the same basis, the production figures of the Tennessee company for the entire year 1907 have been included in the results shown below for that year. The figures are in tons, except cement, which is in barrels:

Products.	1907. Tons.	1908. Tons.
<i>Iron Ore Mined</i>		
In Lake Superior ore region.		
Marquette range.....	1,170,496	830,087
Menominee range.....	1,625,358	1,021,598
Gogebic range.....	1,425,457	1,078,025
Vermilion range.....	1,724,217	927,206
Mesabi range.....	16,458,273	11,272,397
In Southern ore region.		
Tennessee Co.'s mines.....	1,576,757	1,533,402
Total.....	23,980,558	16,662,715
<i>Coke Manufactured.</i>		
Bee-hive ovens.....	12,716,013	7,591,062
By-product ovens.....	828,751	578,869
Total.....	13,544,764	8,169,931
<i>Coal Mined, not used in making coke.</i>	3,550,510	3,008,810
<i>Limestone quarried.</i>	3,201,222	2,186,007
<i>Blast Furnace Products.</i>		
Pig iron.....	11,234,447	6,810,831
Spiegel.....	130,554	74,716
Ferromanganese and silicon.....	57,794	48,861
Total.....	11,422,795	6,934,408
<i>Steel Ingot Production.</i>		
Bessemer.....	7,556,460	4,055,275
Open-hearth.....	5,786,532	3,783,438
Total.....	13,342,992	7,838,713
<i>Rolled and Other Finished Steel Products for Sale.</i>		
Steel rails.....	1,879,985	1,050,389
Blooms, billets, slabs, sheet and tinplate bars.....	761,195	551,106
Plates.....	894,364	312,470
Heavy structural shapes	587,954	313,733
Merchant steel, skip, hoops, bands and cotton ties.....	1,338,833	577,591
Tubing and pipe.....	1,174,629	654,428
Rods.....	126,095	93,406
Wire and products.....	1,481,226	1,275,785
Sheets—black, galvanized and tinplate.....	1,070,752	770,321
Finished structural shapes	719,887	403,832
Angle and splice bars and other railjoints.....	195,157	84,669
Spikes, bolts, nuts and rivets.....	67,991	40,252
Axles.....	189,006	24,057
Sundry steel and iron products.....	77,463	54,893
Total.....	10,564,537	6,206,932
Spelter.....	31,454	28,057
Sulphate of iron.....	34,540	26,411
Universal portland cement, bbl.....	2,129,700	4,535,300

The total falling off in rolled and other finished-steel products—which is the final form in which the Corporation's products reach the buyer—was 4,357,605 tons, or 41.2 per cent.

DOMESTIC AND FOREIGN TRADE

The decrease in domestic sales of all

products last year was 41.9 per cent.; in foreign trade, only 21.2 per cent. The report says: "The export business constituted about 12.4 per cent. of the entire shipments of rolled and other finished-steel products. The average prices received for exported material of all kinds, while somewhat lower than were received in the preceding year, compared very favorably with the average for the domestic business. The advantage to both the manufacturer and the employees of the permanent establishment of a fair volume of foreign trade, especially during periods of lesser activity in the United States, was most forcibly illustrated during 1908. An essential feature necessary to the successful conduct of a foreign trade, and one that can be obtained only by remaining continuously in the business, is that the manufacturer, his grades of goods and his methods shall become known to the consumers. Otherwise the use of the foreign market is largely limited to the so-called 'dumping' process, which is only accomplished at profitless prices. In the domestic trade the prices received for steel products shipped in 1908 averaged substantially the same as those received in the preceding year."

PRODUCTIVE CAPACITY

The total expenditures for new property and construction since the organization of the Steel Corporation have been \$348,032,939, including betterments. The effect is shown in the following statement of productive capacity in 1901 and at the close of 1908:

	1901.	1908.
Blast furnace products.....	7,440,000	14,990,000
Steel ingots.....	9,435,000	17,070,000
Finished iron and steel.....	7,719,000	12,940,000
Cement, bbl.....	500,000	6,100,000

This growth has not, however, done much more than keep pace with the general increase in the trade, as is shown by the following table, which gives the proportions of the total output of the United States furnished by the Steel Corporation and by other manufacturers in 1901 and 1908:

	1901.		1908.	
	U.S. Co.	Others.	U.S. Co.	Others.
Pig iron.....	43	2	56	8
Bessemer steel	70	1	29	9
Ingots.....	58	8	41	2
Open-hearth steel	66	2	33	8
Total steel.....	66	2	56	4

The Steel Corporation has always been weakest on the pig-iron side. This will be remedied by the new furnaces at Gary. The Gary plant will also increase the proportion of steel to the total output of the company.

EMPLOYEES OF THE CORPORATION

The average number of employees at all plants during the year was:

	1907.	1908.	Changes.
Manufacturing.....	151,870	118,557	D. 33,113
Coal and coke.....	21,447	17,104	D. 4,343
Iron ore.....	16,462	13,135	D. 3,327
Transportation.....	18,133	14,165	D. 3,968
Miscellaneous.....	2,468	2,190	D. 278
Total number.....	210,180	165,211	D. 44,969

The total amount paid in wages and salaries was \$160,825,822 in 1907, and \$120,510,829 in 1908; a decrease of \$40,314,993.

The average payment per employee was \$765.19 in 1907, and \$729.44 in 1908; a decrease of \$35.75 last year.

In January, 1909, there was offered to the employees of the United States Steel Corporation and of the subsidiary companies the privilege of subscribing for 18,000 shares of preferred stock and 15,000 shares of common stock at the price of \$110 per share for the former and \$50 per share for the latter. The conditions attached to the offer and subscription were substantially the same as those under which preferred stock had been offered in each of the previous six years, excepting as to the subscription price. Moreover, because of the lower price at which the common stock was offered, as compared with the price for the preferred, the special bonus to be paid subscribers who retain their stock for five years was fixed for the common shares at one-half the amount of bonus which is to be received by holders of preferred shares. Subscriptions were received from 19,192 employees for an aggregate of about 23 per cent. in excess of the amount of stock offered. Subscriptions were reduced *pro rata*, except that employees subscribing for stock equaling a value at the subscription price of \$110 or less per employee, were allotted the full amount subscribed for. The total number of shares allotted was 18,000 of preferred and 15,318 of common stock. At Dec. 31, 1908, there were 22,960 employees who had purchased preferred stock under offers made by the Corporation, and who on that date either held the certificates of stock or were making monthly payments on account of the purchase price thereof.

TRANSPORTATION PROPERTIES

The railroads worked by the Corporation include 87.3 miles main line and 575 miles branches and spurs owned, and 435 miles leased; a total of 1883 miles, on which there are 304 miles of second track and 754 miles of sidings. The equipment owned includes 660 locomotives and 45,682 cars. The transportation equipment on the Lakes includes 76 steamships and 29 barges. In connection with these there are owned large shipping docks at Two Harbors and Duluth on Lake Superior, and receiving docks at several Lake Erie ports.

GENERAL IMPROVEMENTS

Notwithstanding the industrial depression, new work of considerable magnitude was authorized during the year, principally by the coke properties, to provide the added fuel requirements called for by the additional furnaces completed and nearing completion at Gary, Carrie, Duquesne and

Youngstown; by the iron ore properties in opening and developing mines in order to supply the increased ore tonnage required by these additional furnaces; the increase in the lake transportation facilities by the purchase of two additional 11,000-ton ore steamers; and by the Tennessee company in opening new ore mines and rehabilitating and enlarging the capacity of its blast furnaces. There was also commenced near the close of the year an extension of the cement plant at Universal, Penn., which will increase the daily capacity of this plant from 4000 to 10,000 bbl. With the completion of this extension the annual capacity of the cement plants operated by the Universal Portland Cement Company—a subsidiary company—will be 3,200,000 bbl. of Universal portland cement. In the year 1908 there were shipped to customers 4,138,757 bbl. of cement, against 2,322,875 bbl. in 1907. This increase was made possible through the completion and placing in operation late in 1907 of plant No. 4, at Buffington, Ind., and plant No. 5, at Universal.

At the close of the year there were unexpended on appropriations authorized for construction and improvement purposes the following sums: For all properties exclusive of Gary, \$28,200,000; for Gary, \$22,500,000; total, \$50,700,000. It is estimated that about 75 per cent. of this total will be used during the current year.

OPEN-HEARTH STEEL

During the last 18 months the subsidiary companies of the Corporation have increased their open-hearth steel capacity by 3,052,000 tons. This includes 500,000 tons of steel capacity controlled by the Tennessee company. During the same period the bessemer steel capacity of the subsidiary companies was reduced—by reason of substitution of open-hearth for bessemer—by 746,000 tons, leaving a net increase in the total steel capacity of 2,306,000 tons, of which 1,806,000 tons resulted from enlargements of old plants and the new plant at Gary, and 500,000 tons by the addition of the Tennessee company.

THE GARY PLANT

All of the construction work on account of the manufacturing plant at Gary, Ind., the city of Gary and the terminal railroad work adjacent thereto was carried on continuously and actively during the past year.

At the manufacturing plant four of the blast furnaces have been completed, three being now in operation. The first pig iron was produced on Dec. 21, 1908. The remaining four blast furnaces now under construction will be completed during the year 1909. Of the 56 open-hearth furnaces authorized to be constructed, one unit of 14 furnaces is completed, another unit of 14 furnaces is nearing completion and a third unit of 14 furnaces will be completed during the current year. Several open-hearth furnaces in the first unit are

now in operation, the first steel having been produced on Feb. 2, 1909. The rail mill is completed and is now in operation, the first rail having been rolled on Jan. 24, 1909, from steel ingots supplied from other plants. The billet mill will be completed by July 1, 1909. Construction work on the 160-in. plate mill, on a group of merchant mills and on the car-axle plant is well under way, the expectation being that all of these finishing mills will be completed and in operation before the close of the present year. A full complement of mechanical shops, including machine shop, foundry, pattern shop, blacksmith shop and roll shop, together with necessary equipment and machinery, has been completed and the several shops are now in operation, furnishing economical facilities for aiding in the general construction work and in the operation of the plant. The vessel slip and docks, including ore-handling apparatus, have been completed. The ore docks have a capacity for handling and storing 2,000,000 tons of iron ore. The organization of the operating force has been developed as the several mill departments have approached completion and at the present time the plant is in readiness to produce pig iron, steel ingots and open-hearth steel rails.

The Iron and Steel Tariff

The bill submitted to Congress by the Ways and Means Committee makes many reductions in iron and steel duties. Iron ore is placed on the free list. The other proposed rates on principal items are shown below, in comparison with the present rates:

	Present Tariff.	New Law.	Change.
Pig iron, per ton.	\$4.00	\$2.50	D. \$1.50
Scrap iron and steel, per lb.	4.00	0.50	D. 3.50
Bar iron, lb.	0.008	0.004	D. 0.004
Small bars, rounds, etc., lb.	0.005	0.004	D. 0.001
Charcoal bars and rods, ton.	12.00	6.00	D. 6.00
Cold rolled bars, additional, lb.	0.0025	0.00125	D. 0.00125
Structural shapes, lb.	0.005	0.003	D. 0.002
Plates, over No. 10 gage, lb.	0.005	20%	
Sheets, under No. 10 gage, lb.	0.007	0.005	D. 0.002
Sheets, under No. 20 gage, lb.	0.008	0.006	D. 0.002
Sheets, under No. 25 gage, lb.	0.011	0.008	D. 0.003
Sheets, under No. 32 gage, lb.	0.012	0.009	D. 0.003
Polished sheets, lb.	0.020	0.0175	D. 0.0025
Steel ingots and blooms.	0.003 to 0.047	0.00175 to 0.046	D. 0.00125 to 0.001
Rails, lb.	0.0035	0.00175	D. 0.00175
Rail joints, etc., lb.	0.004	0.002	D. 0.002
Tin plates, lb.	0.015	0.012	D. 0.003
Wire nails, lb.	0.005	0.0025	D. 0.0025
Cut nails, lb.	0.006	0.005	D. 0.001
Loco- and car wheels, lb.	0.015	0.0125	D. 0.0025

A maximum and minimum feature is incorporated in the bill by the introduction of a special section which, in the case of metal products imported from countries

which do not grant their minimum tariff to American goods, levies a retaliatory additional duty of 20 per cent., except as to pig iron and car wheels, upon which the retaliatory rates shall be the rates of the Dingley act.

The definition of steel in the bill is as follows: "All metal produced from iron or its ores, which is cast and malleable, of whatever description or form, without regard to the percentage of carbon contained therein, whether produced by cementation, or converted, cast, or made from iron or its ores by the crucible, bessemer, Clapp-Griffith, pneumatic, Thomas-Gilchrist, basic, Siemens-Martin, or open-hearth process, or by the equivalent of either, or by a combination of two or more of the processes or their equivalent of any, or by a combination of two which produces from iron or its ores a metal either granular or fibrous in structure, which is cast and malleable, excepting what is known as malleable-iron castings, shall be classed and denominated as steel."

Proposed Tariff Changes on Metals

Changes in the duties on metals, as proposed in the tariff bill recently introduced, are given in the table below. Of course, material alterations may be made before the bill passes:

	Present, Cents.	New Law, Cents.	Change, Cents.
Lead in ores, lb.	1.500	1.500	
Lead in metallic form, lb.	2.125	1.800	D. 0.625
Lead in manufactures, lb.	2.500	1.875	D. 0.625
Zinc, metallic, lb.	1.500	1.000	D. 0.500
Zinc sheets, lb.	2.000	1.250	D. 0.750
Zinc in ore, lb.	free	1.000	
Antimony, metal, lb.	0.750	0.750	
Nickel and nickel oxide, lb.	6.000	6.000	
Quicksilver, lb.	7.000	7.000	
Aluminum, lb.	8.000	7.000	D. 1.000
Aluminum, sheets, etc., lb.	15.000	11.000	D. 2.000

Duties of 25c. per lb. are provided for on copper sheets, rods, tubes and other manufactured forms; and of 2c. per lb. on sheathing or yellow metal.

Queensland Gold

Gold production in Queensland in February is reported at 32,500 oz. fine, including 5200 oz. from copper ores. For the two months ended Feb. 28 the production was 57,000 oz., or \$1,178,100. Of this total only 900 oz. was from placers.

The coal output for Natal during December, 1908 (*So. African Min. Journ.*, Jan. 23, 1909) was 60,837 tons bunker coal and 49,012 tons exported, a total of 109,849 tons.

The New Tariff Bill

SPECIAL CORRESPONDENCE

The Payne tariff bill was introduced in the House of Representatives March 17, was referred to the House Ways and Means Committee and was reported by that body on the morning of March 18, after 10 minutes of discussion. The bill is accompanied by a report from Chairman Payne summarizing the measure and pointing out the reasons for attempting a revision of the tariff at the present time. Discussion was begun in the House on the morning of March 22.

Notes of the principal proposed changes in the metal and the iron and steel schedules were published in the *JOURNAL* of March 20, and elsewhere in the present issue.

MAXIMUM AND MINIMUM RATES

The special characteristic of the Payne bill, differentiating it from the tariff measures that have preceded it, is that it provides a maximum and minimum schedule of duties, the latter to become effective at once upon the enactment of the bill, the former to go into effect against such countries as refuse to give our exports entering their ports rates as favorable as those accorded to the goods of any other country. These maximum rates apply to practically all of the items enumerated in the metal schedule. To the items enumerated in 41 of the 80 paragraphs in the metal schedule the Dingley rates in force prior to the passage of the new tariff would be applied as the maximum, while to the rest maximum rates 20 per cent. higher than the minimums mentioned in the proposed new schedules would apply. Those which would take the Dingley rates are chiefly the manufactures of iron and steel, hardware, and the like. Those which would take the advance of 20 per cent. over the minimum, would include lead, zinc, the ferro-alloys, metallic mineral substances in a crude state and some machinery.

DRAWBACKS ON MANUFACTURES EXPORTED

The drawback section is acceptable to metal-manufacturing interests as it will permit the substitution of equal quantities of imported material in exported manufactured products, instead of requiring as at present the absolute identification of the materials entering into each product.

SMELTING IN BOND

Special criticism is offered regarding the provision for smelting in bond, which is less satisfactory than the old one, notwithstanding the efforts to secure a liberalization of the requirements of the law. The section in question is No. 28, and reads as follows:

"SEC. 28. That the works of manufacturers engaged in smelting or refining

metals, or both smelting and refining, in the United States may be designated as bonded warehouses under such regulations as the Secretary of the Treasury may prescribe: *Provided*, That such manufacturers shall first give satisfactory bonds to the Secretary of the Treasury. Ores or metals in any crude form requiring smelting or refining to make them readily available in the arts, imported into the United States to be smelted or refined and intended to be exported in a refined but unmanufactured state, shall, under such rules as the Secretary of the Treasury may prescribe, and under the direction of the proper officer, be removed in original packages or in bulk from the vessel or other vehicle on which they have been imported, or from the bonded warehouse in which the same may be, into the bonded warehouse in which such smelting or refining, or both, may be carried on, for the purpose of being smelted or refined, or both, without payment of duties thereon, and may there be smelted or refined, together with other metals of home or foreign production: *Provided*, That each day a quantity of refined metal equal to 95 per centum of the amount of imported metal smelted or refined that day shall be set aside, and such metal so set aside shall not be taken from said works except for transportation to another bonded warehouse or for exportation, under the direction of the proper officer having charge thereof as aforesaid, whose certificate, describing the articles by their marks or otherwise, the quantity, the date of importation, and the name of vessel or other vehicle by which it was imported, with such additional particulars as may from time to time be required, shall be received by the collector of customs as sufficient evidence of the exportation of the metal, or it may be removed under such regulations as the Secretary of the Treasury may prescribe, upon entry and payment of duties, for domestic consumption, and the exportation of the 95 per centum of metals hereinbefore provided for shall entitle the ores and metals imported under the provisions of this section to admission without payment of the duties thereon: *Provided further*, That in respect to lead ores imported under the provisions of this section the refined metal set aside shall either be re-exported or the regular duties paid thereon within six months from the date of the receipt of the ore. All labor performed and services rendered under these regulations shall be under the supervision of an officer of the customs, to be appointed by the Secretary of the Treasury, and at the expense of the manufacturer."

PATENT PROVISIONS

Sharp dissatisfaction has been expressed with the provision of the bill which includes the plan for discrimination against foreign countries that attempt to subject our patents to unfair treatment. This

provision is found in Section 41 and reads as follows:

"SEC. 41. That whenever a patent is issued by the United States to any citizen or subject of a foreign country it shall be subject with respect to manufacture thereunder in this country to all the limitations, conditions and restrictions that are imposed by the country of said citizen or subject upon the manufacture in that country under patents issued therein to citizens of the United States."

Transvaal Gold

Gold production in the Transvaal in February is reported at 550,645 oz. from the Witwatersrand and 14,573 oz. from the outside district; a total of 565,218 oz. This is a decrease of 49,995 oz. from January, which was due entirely to the shorter month; the daily average having been 19,842 oz. in January and 20,183 oz. in February. For the two months ended Feb. 28 the total was 1,102,258 oz. in 1908, and 1,180,331 oz.—or \$24,307,442—in 1909; an increase of 78,073 oz. this year.

The labor report shows an increase of 7174 Kafirs in February, and a decrease of only 11 Chinese; the total number on Feb. 28 being 157,838 Kafirs and 10,034 Chinese.

The February report includes 69 mines, the mills having 8930 stamps in all. The total ore crushed during the month was 2,338,091 tons, and the general average result was \$10.43 per ton.

Indian Gold Mines

The production of the Kolar district in Mysore, India, in February was 40,076 oz. bullion, being 5238 oz. less than in January and 2361 oz. less than in February, 1908. The decrease was due to a fire in the Nundydroog mine. The total for the two months ended Feb. 28 was 86,340 oz. bullion in 1908, and 85,300 oz. in 1909; a decrease of 950 oz. The bullion reported this year was equal to \$1,588,570, or 76,851 oz. fine gold.

The output of the two producing mines in the Deccan—the Hutti Nizam and the Dharwar Reefs—was 2083 oz. in February. For the two months ended Feb. 28 it was 3317 oz. in 1908 and 4131 oz. in 1909; an increase of 814 oz. this year.

Wherever considerable ore is trammed, all turn sheets should be eliminated and curves used, for most up-sets occur at such points, and, besides, slewing a truck is hard work and many times an avoidable loss of energy.

The Saint Croix safety-catch device, which is designed to stop the cage gradually and independently of the guides, is being tried at the Marcus shaft of the Langlaagte Estate, South Africa.

Colliery Notes

All safety lamps should be carried steadily and not jerked or held in a slanting position.

It is estimated that the world contains 200,000 square miles of peat bogs, while of this total area, 36,000 square miles are located in the United States. Canada is credited with 37,000 square miles; Germany, 10,000 square miles, and Ireland 1100 square miles.

Recent estimates place the original supply of coal in Indiana at 44,169,000,000 short tons. The aggregate production of coal in Indiana to the close of 1907 amounted to 159,440,390 short tons, of which 13,985,713 tons, or practically 9 per cent. was produced in 1907. The exhaustion represented by this production is figured at 239,000,000 tons or 0.54 per cent. of the original supply. The coal remaining in Indiana is, therefore, nearly 300 times the production at the close of 1907.

In coaling a large steamer in a Japanese port, about 600 persons are employed. The coal is placed in small baskets, holding a trifle more than a peck, and is passed along the line until it reaches the ship. It takes these 600 people just seven hours to load a steamer with 1500 tons of coal. They receive for this work about 20c. each, in American money, making the cost of coaling the ship about \$120. The work could not be accomplished for much less by machinery.

The practice of robbing one or two pillars at varying intervals of time, is most ill-advised. Robbing should not be started until a certain district, comprising say eight or ten pillars, has been prepared for quick drawing. All of the pillars should be brought back together as uniformly and quickly as possible. This plan insures the pressure being brought to bear equally on each pillar, and besides bringing the coal down in larger lumps, causes the roof to subside evenly, preventing a loss of coal through a squeeze.

In firing a furnace, it is best to have the coal broken to a size no larger than a man's fist. The reason for this is, that large lumps do not ignite promptly, and their presence also causes holes to form in the fire, which allow the passage of too much air. Do not land the coal in a heap, but spread it over as wide a space as possible. Fire one side of the furnace at a time, so that the other side containing a bright fire will ignite the volatile gases from the fresh charge. Carry as thick a fire as the draft will allow. Fire little and often, rather than heavy and seldom. In case of a sudden interruption in the amount of steam being used, it is best to regulate the draft by the bottom or ash-pit doors rather than by the stack dampers; when the latter are used, it tends to produce a smoky chimney.

We of the United States, are not alone in our troubles over the questions of labor and wages. In Germany, there is a popular demand for a reduction in the price of coal, and the mine owners reply that such action is impossible owing to the high wages paid miners. The German miners last year earned approximately \$1.50 a day and other workers in the mines about \$1. These rates were an increase over those of 1905 of about 26 per cent. for the miners, 20 per cent. for other workers underground and 14 per cent. for laborers. German mine owners are now confronted by a number of new laws which will require them to pay a total of about \$2,500,000 for the purpose of invalid and accident insurance. To this same fund, the mine workers are required to contribute a similar sum.

Among the new rules to govern the coal industry in Ohio, the mine inspectors have prescribed the following: (1) No wires carrying current shall be extended beyond the outside corner of the last breakthrough between entries or rooms. (2) In no case shall an electric wire be attached to a pipe-line in any mine, and all pipe-lines must be protected from contact with bonded rails or wires used for conducting power for motor haulage or any other purpose. (3) All ventilating fans operated by electricity shall have a direct wire from the generator. (4) No running switches shall be made, either by haulage or gathering motors, where men are traveling in or out of mines. (5) No person shall be permitted to ride on loaded cars or motor, or high-speed haulage trips, unless a special trip is run for the purpose of taking employees in and out of the mine.

In striking contrast to the laxity of our employers' liability laws is the policy of foreign countries, 22 of which have enacted legislation recognizing the principle that the workman is entitled to compensation for injuries from accidents received in the course of his employment. There is variation in the provisions of the foreign laws, but as a general rule, compensation is not payable unless the injury causes disablement for a specified number of days or weeks. The employer may usually be relieved from the payment of compensation if he can prove that the injury was caused intentionally or by wilful misconduct; however, in none of these 22 countries does ordinary negligence on the part of the injured employee work a forfeiture of the right to compensation. In all the countries with the exception of Sweden, the compensation is based upon the wages of the injured person. The acts of nearly all of the countries are framed with a view of obviating the necessity for instituting legal proceedings. Agreements, therefore, are usually made amicably between the employers and the victims of an accident.

The plan of heating the air forced into a mine, for the purpose of raising the

humidity, especially in winter time, must be accompanied by an efficient system of putting a large amount of moisture into this air. Up to the present time, the means generally employed for accomplishing this end have been rather primitive, so that it is interesting to note that a system originating in Germany and meeting with much success there, has been introduced into this country. This general scheme consists of mechanically spraying in a fine mist form through a number of specially constructed spray nozzles. The construction of these nozzles is such that when water is forced through them under a pressure of from 50 to 100 lb., it issues forth in the form of a mist without any drops. The nozzles are distributed at intervals in the air shafts and entries through which the air currents pass, and the full discharge from the nozzles is instantly caught up by the current of air and is carried to the remotest corners of the mine; this plan keeps the walls, roof and floor of the mine moist. The system being introduced is known as the Koerting spray system, and the nozzles are being manufactured by the Schütte & Koerting Company, Philadelphia, Pennsylvania.

The question of a proper capping for a winding rope is important. The former practice of turning the wires back in order to form the bulge for the capping to grip has resulted in many accidents of cage falling to the bottom of the shaft. The later scheme of having the wires of the rope gripped within a cone of white metal has proved satisfactory at a number of collieries. Close attention should be given to see that this latter method is properly carried out. The following points are essential to remember: 1. Bind the rope with soft iron wire, at the point at which it is to be opened out. 2. Carefully straighten the wire; open out each wire and straighten the strand curves, so that the wires cannot possibly twist together again. 3. Thoroughly clean each wire, taking off all grease and dirt close up to the wire wrapping. 4. Thoroughly dust the wire with resin dust so that the fluid white metal will freely flow around each wire. 5. After drawing the wires down into the steel socket, a hemp or cloth wrapping may be used to prevent the metal running out. Do not put the socket into use if the white metal does not show outside the steel socket. One of the best mixtures of white metal is the following: Lead, 60 per cent.; tin, 30 per cent.; antimony, 9 per cent.; bismuth, 1 per cent. The antimony adds to the hardness, the bismuth lowers the temperature of fusion and gives a slight expansion in cooling. It is advisable to never remelt and use the same metal a second time. There is no truth in the statement that the hot fluid metal affects the temper of the wires of the rope.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Pres and Treas. ROBERT MCKEAN, Sec'y.
505 Pearl St., New York.

London Office: 6 Boulevard Street, London, E. C., Eng.
(CABLE ADDRESS: "ENGINEERING, N. Y.")

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs. Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for February, 1909, was 42,000 copies.

March 6..... 12,000

March 13..... 10,000

March 20..... 10,000

March 27..... 10,000

None sent free regularly, no back numbers.

The Steel Corporation Report

The report of the United States Steel Corporation covers such a wide range of interests and deals with such large figures that it requires much study and careful analysis to get at its full meaning. Not that it is obscure or involved; the present report, like its predecessors, is a full and fair statement of the business transactions of the year. No attempt has been made to cover up the depression in business which marked the period under review, or to disguise the losses of business in comparison with previous years. How great those losses were can be illustrated by a few figures. Thus the gross sales, while approaching very nearly \$500,000,000 in amount, were less than those of 1907 by \$274,706,928, or 36.3 per cent. The net earnings, after deducting all working and general expenses, depreciation and ordinary renewals, decreased \$69,116,963, or 42.9 per cent.; while the surplus over all charges—the final net profit—was diminished by \$58,836,850, or 56.3 per cent. The higher proportion of loss in the final net surplus is explained by the fact that the interest and fixed charges are practically the same in a lean business year as in a good one. Perhaps the remarkable point is that with a loss of over one-third of the gross earnings the surplus for the year should have been sufficient to pay the usual dividends, without drawing upon the company's accumulated profits.

The loss in earnings was due entirely to smaller business, since the report tells us that there was little change in the prices realized. What the reduction was is shown by the table of production which notes decreases of 31.7 per cent. in the make of pig iron; 41.2 in steel ingots, and 41.3 in finished iron and steel. The tables are not carried far enough to make statements of average returns and costs practical. A rough determination may be made, however, by taking the quantity of finished iron and steel products, which are the forms in which by far the greater part of the Corporation's output reaches the consumer. On this basis the gross earnings of 1907 show an average of \$71.65 per ton, and the net earnings \$15.24; the figures for 1908 being \$77.71 and \$14.80 per ton. These averages are, of course, too high, as they disregard the sales of steel billets and other half-finished forms, and of by-products, like copperas, cement,

etc.; but they will serve some purposes of comparison.

As already noted, the final net earnings were sufficient to continue the payment of dividends at an unchanged rate; but the Corporation suspended for the year the appropriations for new construction—that is, for actual additions of property, as distinguished from renewals and the making good of depreciation. Such appropriations in 1906 and 1907 amounted to \$54,000,000 in each year. Since its organization the Corporation has spent for such additions a little over \$348,000,000, the effect of which has been to double its pig-iron production, to increase its capacity for making steel about 80 per cent. and for finished forms 67 per cent. This has been a wise policy; indeed, a necessary one, if it was to maintain the position in the trade. After all, the additions did not do more than keep pace with the general growth in capacity for making iron and steel. In 1908 the proportion of the total output of the United States furnished by the Steel Corporation was very nearly the same as in 1907.

The report deals fully with the financial side of the year's operations, but has little to say of technical matters, or technical progress. One statement of interest, however, is that while the open-hearth steel capacity was increased during 1908 by 3,052,000 tons yearly, the bessemer-steel capacity was decreased by 746,000 tons, owing to the substitution of open-hearth furnaces for converters.

Another proof of the diminished business of the past year is found in the fact that the average of 210,080 employees in 1907 was reduced by 44,969, to 165,211 men in 1908. The Corporation has continued its policy of placing stock with its employees, and at the end of 1908 had 22,960 who were owners of preferred stock.

Very little is said of iron-ore holdings, the subject being apparently avoided, notwithstanding—or perhaps because—of the recent active discussion of the question of iron-ore supplies and their ownership. The only reference is the statement that prospecting and preparation for increased production from the Mesabi properties were actively carried on, though the output last year was less than for three years preceding.

Upon the whole the report is rather better than might have been expected, and is to be commended for its fullness

There is not space here to discuss the question whether its showing would have been different had the Corporation adopted earlier the economic policy to which it has at last been driven. Little or no attempt is made to discuss or defend that policy in the report itself.

Coal Mining as an Investment

Not for many years has the coal-mining industry been so completely enshrouded in a cloud of despondency as at present. Those who are financially interested in the production of coal are dubious as to how they are going to come out, and the more timid, either from inexperience or from short memory, are predicting dire results for the industry. When prices are high and consumption is breaking all records, eyes are shut to the recessions that will come, and similarly during a period of depression, some fear that the days of plenty have permanently forsaken them.

Some prominent operators are now thinking that there will be no improvement in the situation, unless there is a radical change in the conditions that govern the industry. They reason that new mines are being opened in such numbers that production is certain to exceed demand, even when business again reaches the prosperity of 1906-07. It is further asserted that coal mining is disorganized, and that this condition will prevent business from being brought to a profitable basis; also that each independent operator endeavors to mine and market his maximum production, undercutting his neighbor and thus spoiling his own market.

In all times of depression, the same cry has been raised and the prospective investor has been deterred from accepting the bargains presented. Immense fortunes have been made in coal, great profits yet await those who get in on the ground floor, and no well-made investment is surer of greater safety of principal and income than coal mining. The product cannot well be stored in large quantities, which fact alone prevents any great overproduction, while the independent competition in the industry prevents the maintenance of false price standards, such as have prevailed in the steel industry to the detriment of early business resumption.

How many branches of business made a better showing in 1908 than coal mining? Although the production in 1908 was only 88 per cent. of that in 1907, we mined nearly as much bituminous coal in 1908 as was produced in 1906 (a banner year), while the anthracite output in 1908 was considerably larger than in 1906. The average price received at the mines during the last decade has varied but little, and this has been true without there having been any monopolistic control of trade. The recessions have been dictated by commercial conditions, and have always resulted in stimulating rather than in upsetting business.

The production of coal is like a manufacturing business, and the industry as a whole is less speculative than many important industrial undertakings. As in other enterprises, the percentage of profit in coal mining depends on the sagacity of the investor in selecting his opportunity. It is not enough to know that the coal is of superior quality and that from every physical aspect, the venture is meritorious; it is also essential that the investor should be sure of his market. Many inferior seams show greater profits, because of their nearby markets and cheap transportation, than others which produce a superior fuel, but less favorably situated.

The disfavor with which many Eastern capitalists view coal mining is principally due to the exaggerated value placed on some properties that have recently been gathered into important consolidations. The stock of these companies has been sold at a price only justified by earnings during times of great prosperity and maximum production. Investors who have been persuaded to buy into these overcapitalized companies have naturally condemned the whole industry as unprofitable because of their own lack of understanding.

For the man whose judgment is sound and vision is keen, coal mining offers attractive opportunities. The cry of overproduction is no more serious now than it was in 1902, and along with improved methods of mining, that not only insure cheaper production, but also a greater percentage of recovery, the prices paid per ton at the mines are higher now than in 1902. It is to be admitted that labor and material now cost more, but the slight increase in them is offset by the advance in the art of mining, which now enables a recovery of 90 per cent. or more as com-

pared with 70 or 80 per cent. a few years ago.

The Proposed New Tariff

In the bill brought in by the Ways and Means Committee on March 17 the changes of most interest to the mining industry are those affecting iron and steel, lead and spelter, and the ores of those metals. Iron ore on the free list will be of great advantage to the independent steel makers on the seaboard, which have been obtaining Cuban ore. It will enable them to produce pig iron materially cheaper, which ought to be to the advantage of consumers, without adversely affecting any domestic iron-mining enterprises of consequence. The removal of the duty on pig iron and the principal steel products will hardly lead to any increase in the importation thereof at the present time. The effect will be rather to restrain the rise of domestic prices at another boom period.

The changes proposed as to lead and zinc are likely to be disturbing. If we may judge from the range of prices during the last 10 years, lead could have been frequently imported at a payment of a duty of 1½¢. per lb. At present prices it could not be profitably imported, and this will probably be always the case when lead at New York is 4 to 4½¢., which is not much below the normal of the market. The chief effect of the reduction in the lead tariff also will be to restrain an excessive rise of prices. It has been erroneously reported, by ourselves included, that the tariff on lead in ore is to be reduced to 1¢. per lb. It had been so reduced, but at the last minute, after Mr. Payne's statement had been given out, the old rate was restored.

The proposed change in the tariff on zinc and zinc ore will increase the cost of raw material to the smelters, while they will be deprived of part of their protection against foreign producers. The effect of this tariff will be to raise the price of spelter, which is what the advocates of the tariff on ore desire to do.

It is to be remarked that the bill before Congress at present is only a proposal, and it will be a long time to its introduction and enactment, during which many changes may be made, wherefore the final act may bear but little resemblance to that which is now proposed.

Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Extraction of Zinc from Mixed Ore

On account of the mixed character of the ore which I have had to smelt during the last three years, containing an average, without selecting, of about 3 per cent. copper, and 20 per cent. zinc as sulphide with considerable silver and gold (the remainder being made up of 18 per cent. heavy spar, 18 per cent. sulphur, 12 per cent. iron, 15 per cent. carbonate of lime, 8 per cent. silica and 2 per cent. lead) I have been investigating the different methods of zinc extraction from such ore and have come to the conclusion that the leaching process with ammonia in connection with carbonic acid, after the ore is roasted and reground, is the most suitable for our ore; and if so is suitable for any zinc ore containing sufficient value.

The ammonia does not seem to dissolve anything in the ore except the copper and zinc. Our chemist extracted 99 per cent. of the copper from a rich piece of chalcopryite and about 80 per cent. of the zinc from a sample of zinc sulphide sent him from Arizona, which he did not have ground fine enough; better yet it should be slimed.

We expect to put in a suitable plant to roast the ore properly, regrind to the most suitable fineness, leach out the copper and zinc, siphon and filter off the solutions, and recover the ammonia by distillation, same as in an ice-manufacturing plant. This throws down the zinc and copper precipitate as the ammonia leaves the solution. (In this connection I may state that I precipitated the copper from the solution first with metallic zinc which would have thrown down any gold or silver at the same time if cyanide solution had been added to have extracted them; the equivalent of zinc dissolved to precipitate the copper is recovered with the remainder of the zinc).

I have extracted 73 to 80 per cent. of the zinc from a sample of our fine dust without any regrinding or preliminary preparation of any kind. After roasting and leaching out the zinc, the remaining pulp is much sweeter to smelt, but our chemist claims that the gold and silver can be extracted at the same time by adding calcium cyanide (a very cheap salt one-sixth the value of potassium cyanide) which can be practically used only in connection with ammonia. I think he is right but I have not experimented with it myself.

I have never heard of the ammonia process being tried on a large scale, except at a small plant in Nevada which I understand was a failure on account of lack of capital, and it did not have a continuous still for boiling out the ammonia. This process appeals to me for the reason that after crushing and roasting (any process to recover zinc requires this) it needs but very little power, the solvent ammonia is recovered and the product is pure, suitable for zinc white paint, or it can be reduced to metal. All the other processes require too much acid, which not only dissolves the zinc and copper but other elements at the expense of the acid, making it more difficult to produce pure zinc and too expensive.

I have spent considerable time and money with an electrician trying to produce marketable zinc at a profit with electricity in connection with different acids, and not only found that the chemicals, anodes and power were too expensive, but the zinc produced was not of first class.

The ammonia process, we estimate, will cost \$6.60 per ton at a 50-ton plant 24 miles from the Southern Pacific railroad in California. This will cover drying, crushing, grinding, roasting, slining, gas, ammonia, cyanide, lime, boiling-out still, calcining zinc oxide and producing enough metallic zinc dust to precipitate the copper and precious metals.

S. E. BRETHERTON.

San Francisco, Cal., March 18, 1909.

Has the Value of Gold Depreciated?

I have read with much interest the article by Mr. Ingalls in the JOURNAL of Nov. 28, 1908, and feel convinced that there is a good deal of truth in his ideas. Nevertheless I object to his comparing the world's gold production with that of pig iron, or any other article of general use that might be chosen for the purpose. Pig iron is consumed, and gold is not, at least to a large extent it is not. I intend to say, that this year's production of iron after a few months may be considered no longer to exist; it will be consumed and practically annihilated. The loss of gold, on the other hand, is confined to the wear of currency and to the amount used in the arts, but all the rest joins the world's treasure; it can be used again and again and will remain to be available for financial purposes for centuries to come.

I therefore believe, that diagram 11.

showing the yearly productions of gold and iron, does not fully answer its purpose, and I should like to have it completed by a third curve, in which the proper proportion of each year's gold production is added to the total amount, available at the beginning of that year. I understand quite well, that such a curve would by no means be an easy thing to plot; a suitable beginning point must be assumed and it will be necessary to find out just what amounts were coined and stored in banks each year, the remainder being used for other than financial purposes. And even if one should succeed in tracing that curve, it would not give an accurate idea about the question, since it is probable that vast amounts of coined metal continually pass out of circulation and are hoarded, especially in Asiatic countries.

I believe the truth lies in the interval between the curves plotted and the one I propose, but perhaps nearer to the latter. If considered from this point of view, is not the accumulation of precious metal in circulation faster nowadays than even the growth of industry and commerce?

I should be very pleased if Mr. Ingalls would express his opinion as to this in the JOURNAL.

A. C. DE JONGH.

Ma-Aman, Sumatra, Jan. 24, 1909.

It would be practically impossible, I believe, to plot such a curve as Mr. de Jongh suggests; even if it were, I do not think the result would justify the labor that would be involved. Iron does not cease to exist when it goes into use until it disappears by decay or is otherwise actually lost. Buildings, ships and many constructions are bought and sold directly, or through the stocks and bonds that represent them. They are forms of wealth and gold is the medium of exchange in the barter thereof. How would the world with its present wealth get along with the gold supply of 50 years ago? Wealth and gold supply are both cumulative, save for loss and destruction. The loss of gold and its industrial uses appear to be greater than is commonly supposed. According to Professor de Launay, in his recent book "The World's Gold," the world should have had (at the end of 1907) 2500 millions of pounds sterling of gold in hand, but certainly not more than 1200 millions was to be found in the state of coin, while between 1873 and 1904 alone more than 1360 millions of new gold money were struck. Half of the officially registered output has passed to industrial uses or has been lost. As to the general question of the effect of the recently greatly

increased gold production upon commodity prices, etc., Professor de Launay comes to substantially the same conclusion as I have done.

W. R. INGALLS.

New York, March 20, 1909.

Mining and Milling Florida Phosphates

In the JOURNAL of March 6, 1909, appeared an article entitled "Mining and Milling Florida Phosphates," by C. A. Stone. The statements made therein as to costs of mining, especially as regards that of hard rock phosphate should, I feel, be corrected in justice to the producers of Florida phosphate.

The cost of mining hard-rock phosphate is stated to be from \$2 to \$2.50 per ton; but to anyone conversant with this class of mining, or to any engineer who had made a careful study of the work in question, the figures given are wide of the mark. The cost of mining this class of rock, at a conservative estimate, is not less than \$4.50 to \$5 per ton. In addition thereto a number of the mines are operated under a royalty, varying from \$1 to \$1.25 per ton, payable to the land owners, which must be added to the actual cost of mining. The figures given by Mr. Stone would indicate that very large profits would accrue to the miners, even at existing low prices, whereas this is not the fact of the case when the true cost of mining is arrived at.

The cost of mining pebble phosphate is placed at \$1.50 to \$2.25 per ton. These figures are too low, and in my opinion, from long experience in this class of mining, should be advanced to \$2.25 to \$3 per ton, varying in accordance with the tonnage yield per acre, yardage of overburden to be removed, general efficiency of the mining installation as to power costs, etc.

The incorrect statements made as to cost of mining tend to do serious injustice to the Florida producers of phosphate, and should be corrected. There are a number of inaccuracies in connection with what might be termed the technical portion of this article, but these are of minor importance and hardly worthy of correction.

C. G. MEMMINGER.

Lakeland, Fla., March 12, 1909.

The Jeffrey Crab Locomotive

The article describing our new crab locomotive in the JOURNAL of March 13, was erroneous in the last paragraph, where it was said that this locomotive is not practical where the rooms are driven to the rise. As a matter of fact, this is one of its most practical features.

JEFFREY MANUFACTURING COMPANY

Columbus, O., March 15, 1909.

The Lick Branch Relief Fund

I herewith inclose you a circular which evidently has been sent to mining men or mining engineers. While I think I am as ready as anyone else to help in cases of suffering, it certainly seems to me that it is a little too much to ask outsiders to contribute to matters of this kind. All mining men and companies have their widows and orphans to look out for, and I should think that pride and common decency would suggest that a mining company should look out for its dependents, even to the point of using all of its assets.

If I remember correctly, at the time of the large explosion in Utah, in which 300 lives were lost, the company paid out \$300,000 and did not say a word about it. Although I have every sympathy for the Lick Branch sufferers, it certainly seems to me that the Pocahontas Consolidated Collieries Company should either by itself, or along with its neighbors, make up this relief fund in full.

J. PARKE CHANNING.

New York, March 16, 1909.

[The circular to which Mr. Channing refers is issued by the "Lick Branch Mine Relief Committee," and recites the two explosions (Dec. 29, 1908, and Jan. 12, 1909) in the Lick Branch mine of the Pocahontas Consolidated Collieries Company, by which 117 lives were lost, leaving 53 widows and 76 children under 16 years without means of support. The company has paid for the burial of the victims and has thus far provided for the maintenance of the bereaved families, besides contributing \$5000 to the fund which the committee is now seeking to raise.—

EDITOR.]

A Project in the Choco Region, Colombia

It has come to my attention that an attempt is being made to interest capital in an enterprise based on the beds of the rivers Condoto, San Juan and Iro, of the Choco region, Republic of Colombia.

It would be well for the readers of the JOURNAL to bear in mind that there are good and valid titles existing, which have existed for some years, to the gold and platinum gravels of the beds and bars of these streams, including the dredging rights of their banks, subject, of course, to indemnification of agricultural injury. The taxes of these claims have been paid in perpetuity, and the rights obtained by them are indisputable.

When I learned of the fact that a dredging right covering some of this section had been granted I was in Bogota and protested to an official of the government. He at once called my attention to the fact that the dredging concession given was simply subject to all prior rights, and thus *ipso facto* was null and void regarding

the region to which valid titles were in existence.

A word of explanation may be interesting. Real estate and mining titles are as safe in Colombia as anywhere on earth; but owing to the great area of the country it has been impracticable as yet to make a detailed survey on which all property should be located and geographically recorded at the time of granting title. Therefore, the central government is unaware of what titles may be existing, and grants such rights as are asked for by persons who make the pretension of intending to undertake active development, but always puts in a saving clause respecting prior rights.

It is an easy matter for anyone contemplating serious development of investment in Colombia to have investigations made in the local and departmental registries, and ascertain whether or no there are any previous titles in existence regarding tracts that they desire to obtain. Where the object, however, is not personal investment, but simply a stock-selling scheme, regarding which the promoter knows there is no legal basis, it is well for intending investors to be on their guard. I therefore give this word of warning.

HENRY G. GRANGER.

New York, March 16, 1909.

A Monument to John W. Powell

The sundry civil act for the fiscal year 1910, passed March 3, appropriates \$5000 for a monument or memorial to John Wesley Powell, former director of the Geological Survey, to be erected on the brink of the Grand Cañon of the Colorado in the Grand Cañon Forest Reserve in Arizona, "in recognition of his distinguished public services as a soldier, explorer, and administrator of Government scientific work." The site for this proposed monument was suggested by Powell's memorable trips down the Grand cañon in 1869 and 1872—exploits of perilous venture that naturally appeal to men's sense of the hazardous and the heroic. The language of the act, however, recognizes the fact that Powell's more substantial achievements—his long directorship of the Geological Survey and his persistent championship of irrigation in the arid West when the cause of irrigation seemed hopeless—entitle him to the larger recognition due to the broad-minded scientific prophet working for great ends with courage and zeal to overcome not only popular indifference but narrow-minded opposition. Standing on the edge of the mighty chasm he first explored, his monument should recall not only the venturesome daring of the explorer, but the patient courage of the man of affairs who resolutely sets out, in spite of all obstacles, to achieve a great public work whose results shall endure through all time.

Patents Relating To Mining and Metallurgy

A Selected and Classified List of New Inventions Described during the Past Month in the Publications of the Patent Offices

UNITED STATES AND BRITISH PATENTS

A copy of the specifications of any of these patents issued by the United States Patent Office will be mailed by THE ENGINEERING AND MINING JOURNAL upon the receipt of 25 cents. British patents are supplied at 40 cents. In ordering specifications, correspondents are requested to give the number, name of inventor and date of issue.

ALUMINUM

MANUFACTURE—Improvements in the Manufacture of Aluminum. Henri Herrschmidt, Paris. (Brit. No. 431 of 1908.)

BAUXITE

MANUFACTURE—Improved Process of Manufacturing Products for Refractory Ceramic or Abrasive Uses from Bauxite or Other Aluminous Earths. Erich von Seemen, Paris. (Brit. No. 702 of 1908.)

CALCIUM

MANUFACTURE—Improvements in the Manufacture of Metallic Calcium. Sherard O. Cowper-Coles, Westminster, Eng. (Brit. No. 24,396 of 1907.)

CEMENT

CEMENT CLINKER—Process of and Apparatus for Making Cement Clinker. Carleton Ellis, Larchmont, N. Y., assignor to Ellis-Foster Company, a Corporation of New Jersey. (U. S. No. 910,121; Jan. 19, 1909.)

HYDRAULIC CEMENTS—Art of Making Hydraulic Cements, etc. William H. Harding, Philadelphia, Penn. (U. S. Nos. 908,092; 908,093; 908,094; Dec. 29, 1908.)

KILNS—Improvements in or Relating to Rotary Kilns for Burning Cement. Friedrich J. Poths, Hamburg, Germany. (Brit. No. 13,440 of 1908.)

MANUFACTURE—Process for the Manufacture of Cement. Willoughby E. Synder, Nazareth, Penn. (Brit. No. 15,025 of 1908.)

COAL AND COKE

BRIQUET MACHINE. Frank Burnes, St. Louis, Mo., assignor to American Fuel Company, St. Louis, Mo., a Corporation of Arizona. (U. S. No. 915,332; March 16, 1909.)

BRIQUETTING—Process of Bricketting Coal and the Waste Materials Thereof. George B. Damon, Glenold, Penn. (U. S. No. 914,248; March 2, 1909.)

BRIQUETTING—Process of Producing Bituminous Binders and Compositions. Walter S. Wilkinson, Wytheville, Va. (U. S. No. 915,260; March 16, 1909.)

COKE-OVEN. Horizontal Coke-Oven. Francis J. Collins, Dortmund, Germany. (U. S. No. 915,660; March 16, 1909.)

COKE-OVEN. William B. Smith, Sr., Pittsburg, Penn. (U. S. No. 915,630; March 16, 1909.)

COKE-OVENS—Improvements in Portable Coke-Ovens and Gas Producers, with Portable Base Plates or Hearths, Adaptable for Use as Furnaces or Kilns. Thomas Smith, Newcastle-on-Tyne, Eng. (Brit. No. 839 of 1908.)

SAFETY LAMPS or the Like, Especially Suitable for Use in the Underground Workings of Mines and in Like Places. Ernest A. Hallwood, Morley, Eng. (Brit. No. 1979 of 1908.)

SAFETY LAMPS—Improvements in and Relating to Apparatus for Igniting Mines' Safety Lamps in Underground and Like Places. Ernest A. Hallwood, Morley, Eng. (Brit. No. 25,597 of 1908.)

SAFETY LAMPS—Improvements in and Relating to Mines' Safety Lamps. Thomas Phillips, Rhondda, Glamorganshire, Wales. (Brit. No. 22,001 of 1908.)

SAFETY LAMPS—Improvements in Apparatus for Electrically Igniting Mines' Safety Lamps or the Like. Ernest A. Hallwood, Morley, Eng. (Brit. No. 28,255 of 1907.)

GOLD AND SILVER

ASSAYING—Process of Assaying. Joseph

C. Himes, Goldfield, Nev. (U. S. No. 913,129; Feb. 23, 1909.)

CONCENTRATION—Gold-Concentrating Apparatus. John H. Montgomery, South Omaha, Neb., assignor of three-eighths to Adam Kuehert, Omaha, Neb., and five sixteenths to Martha Montgomery, South Omaha, Neb. (U. S. No. 913,905; March 2, 1909.)

CYANIDE PROCESS—Improvements in the Cyanide Process for Extracting Precious Metals from Their Ores and in Apparatus for Carrying Out Such Process. Communicated from the Just Mining and Extraction Company, Syracuse, N. Y. (Brit. No. 1582 of 1908.)

IRON AND STEEL

ALLOYED STEELS—Improvements in Art of Producing Alloyed Steels. James Churchward, Mount Vernon, N. Y. (Brit. No. 12,883 of 1908.)

BLAST-FURNACE. Samuel H. Hine and William R. Phibbs, Girard, Ohio. (U. S. No. 915,601; March 16, 1909.)

ELECTRIC SMELTING—Method of Operating Electric Furnaces. Paul L. Héroult, La Paz, France, assignor to Société Electrometallurgique Française, Fréjus, Isère, France. (U. S. No. 914,346; March 2, 1909.)

ELECTRIC FURNACE. Paul L. Héroult, La Paz, France, assignor to Société Electrometallurgique Française, Fréjus, Isère, France. (U. S. No. 913,888; March 2, 1909.)

EXTRACTING IRON—Method of Extracting Iron from a Pulverized Charge. Carl G. P. de Laval, Stockholm, Sweden. (U. S. No. 913,405; Feb. 13, 1909.)

ORE-SMELTING FURNACE. John T. Jones, Iron Mountain, Mich., assignor, by direct and mesne assignments, to Jones Step-Process Company, a Corporation of Minnesota. (U. S. No. 12,928; March 16, 1909.)

REFINING—Improvements in, and Relating to the Refining of Steel in Electric Furnaces. Compagnie Bismarckhütte, Bismarckhütte, Germany. (Brit. No. 8929 of 1908.)

TITANIFEROUS IRON ORES—Improvements in or Relating to the Treatment of Titaniferous Iron Ores. Alf Sindling-Larsen, Christiania, Norway. (Brit. No. 27,282 of 1907.)

TIN

DETINNING—Process of Detinning. Harry M. Fernberger, Dollar Bay, Mich., and William M. Murray, Philadelphia, Penn. (U. S. No. 913,275; Feb. 23, 1909.)

DETINNING—Method of Detinning Tin Scrap. Meredith Leitch, Springfield, Mass., assignor to Metal Process Company, New York, N. Y., a Corporation of New York. (U. S. No. 907,061; December 15, 1908.)

ZINC

CHARGING RETORTS—Improvements in Means for Charging the Retorts of Zinc and Other Analogous Furnaces. Emil Der-Delattre, Dorplein, Holland. (Brit. No. 13,822 of 1908.)

EXTRACTION PROCESS—An Improved Continuous Process and Apparatus for the Extraction of Zinc from Its Sulphide. Thomas J. Heskett, Surrey Hills, Victoria, Aust. (Brit. No. 1761 of 1908.)

MINING—GENERAL

DRILLING—Water Attachment for Drill-Steels. James H. Sinclair and Guy L. Neill, Portland, Ore. (U. S. No. 915,230; March 16, 1909.)

MINE PROPS—Improvements in Mine Props. Frederick Nellen, Essen-on-the-Ruhr, Germany. (Brit. No. 21,446 of 1908.)

REMOVING DUST AND GASES—Method of Removing Loose Materials, Dust and Gases from Mines. Frank T. Byers, Mount Pleasant, Penn. (U. S. No. 12,923; reissue Feb. 23, 1909.)

ORE DRESSING

ATMOSPHERIC SMELTING. Charles H. Krause, Keweenaw Bay, Mich. (U. S. No. 914,262; March 16, 1909.)

GRINDING MILLS—Improvements in Drum Mills for Grinding or Crushing. Gerhard Zarniko, Hildesheim, Germany. (Brit. No. 16,724 of 1908.)

ORE SEPARATOR. Alexander S. Campbell, Ortonville, Minn. (U. S. No. 913,258; March 2, 1909.)

PULVERIZING—An Improved Method of and Apparatus for Pulverizing Materials. Joseph de Miniszewski, Kwasow, Poland, and Frank A. Vernon and John C. Vernon, London. (Brit. No. 19,927 of 1908.)

SEPARATING METALS IN SOLUTION—Process of Separating Metals in Solution. Herbert H. Dow, Midland, Mich., and Walter S. Gates, Worthington, Ontario, Canada, assignors to the Ontario Nickel Company, Ltd., Worthington, Canada, a Corporation. (U. S. Nos. 913,708 and 913,709; March 2, 1909.)

METALLURGY—GENERAL

ELECTROLYTIC PRECIPITATION—Method of Precipitating Metals Electrolytically. Arthur Ramén, Helsingborg, Sweden, assignor to Helsingborgs Kopparverks Aktiebolag, Helsingborg, Sweden. (U. S. No. 913,430; Feb. 23, 1909.)

EXTRACTION—Process of Extracting Gold, Platinum, Silver, Nickel, Copper, etc., from Ores. Adolphe Seigle, Lyon, France. (U. S. No. 915,795; March 16, 1909.)

SMELTING—Method of Smelting Ores. James T. Carlick, Johannesburg, Transvaal, assignor of one-half to Basil Stuart Pattison, Johannesburg, Transvaal. (U. S. No. 913,655; Feb. 23, 1909.)

SMELTING-FURNACE—Oil-Heated Smelting-Furnace. August Koch, Hanover-Lst, Germany. (U. S. No. 915,192; March 16, 1909.)

MINING MACHINERY AND APPARATUS

CARTRIDGE for Mining Purposes. Edward Purcell and Samuel Purcell, Pontefract, England. (U. S. No. 910,722; Jan. 26, 1909.)

DEEP-RODING APPARATUS. Wilhelm Schott, Erkelenz, Germany, assignor to the firm of Internationale Bohrergesellschaft, A. G., Erkelenz, Germany. (U. S. No. 909,234; Jan. 12, 1909.)

ROCK-DRILLING ENGINE—Gasoline-Operating Rock-Drilling Engine. Roland S. Trott, Denver, Colo. (U. S. No. 915,320; March 16, 1909.)

ROCK-DRILLING MACHINES—Improvements in Rock-Drilling Machines. Communicated from the Rogers-Rand Company, New York City. (Brit. No. 13,872 of 1908.)

ROCK-DRILLING MACHINES—An Improvement in Rock-Drilling Machines. Frederick A. Parnell and Albert L. Underwood, Clonsdale, London. (Brit. No. 14,529 of 1908.)

ROCK-DRILLS—Improvements in or Relating to Air-Operated Rock-Drills. Joseph Knight, Holyhead, Anglesey, and Richard S. S. Reilly, Liverpool. (Brit. No. 4827 of 1908.)

ROCK-DRILL. John A. Traylor, Denver, Colo. (U. S. No. 913,928; March 2, 1909.)

TUNNEL-BORING DEVICE. Reginald H. Keays, New York, N. Y. (U. S. No. 912,575; Feb. 16, 1909.)

METALLURGICAL MACHINERY AND APPARATUS

CHARGING BLAST FURNACES—Apparatus for Charging and Distributing the Stock in Blast-Furnaces, etc. William C. Mitchell, Chesterfield, England. (U. S. No. 908,594; Jan. 5, 1909.)

ELECTRIC FURNACES—Improvements in or Relating to Electric Furnaces. Albert Le Roy Marsh, Lake Bluff, Ill. (Brit. No. 19,265 of 1908.)

ELECTRIC FURNACES—Improvements Relating to Electric Furnaces. Hugo Holberg, München, Germany. (Brit. No. 13,257 of 1908.)

ELECTRIC FURNACES—Improvements in Electric Furnaces. Jean Ronneau, Paris. (Brit. No. 8904 of 1908.)

Personals

Mining and metallurgical engineers are invited to keep *THE ENGINEERING AND MINING JOURNAL* informed of their movements and appointments.

R. Gilman Brown, who is now in London, expects to go to Manchuria soon.

W. E. Simpson is now manager of the San Francisco del Oro mine, Chihuahua, Mexico.

F. C. Greene, Cleveland, Ohio, is designing equipment for a coal plant in Alberta, Canada.

Henry Krumb is directing developments at the Inspiration mine, near Globe, Arizona.

Edward L. Dufourcq has returned to New York from a trip to Mexico and California.

A. F. Kuehn has returned to the United States from Chile where he had been for four months.

Ralph Nichols, who is now operating at Gilmore, Idaho, was a visitor in New York last week.

Edwin A. Austin has returned from Colombia to San Francisco and will soon start for the Yukon.

Hermann A. Keller, who has been spending the winter in Europe, expects to return to New York early in April.

Edwin E. Chase recently returned to Denver, Colo., from Juneau, Alaska, and has now gone to Oaxaca, Mexico.

W. J. Olcott, now vice-president, will succeed Thomas F. Cole as president of the Oliver Iron Mining Company.

W. S. Keith, of Seattle, is making an examination of a deposit of chrome ore on Fidalgo island, Skagit county, Washington.

Prof. Dr. George Lunge, of Zürich, Switzerland, has been elected an honorary member of the Chemical Society of London.

H. Foster Bain, recently State geologist of Illinois, has become associate editor of the *Mining and Scientific Press*, of San Francisco.

Henry F. Lefevre recently returned to New Orleans from Panama, and sailed for Nicaragua on March 17, to be gone about three months.

A. H. Wethey, who has been spending the winter in Europe, returned to New York last week, and after spending a few days here proceeded to Butte.

James Epperson has been appointed State mine inspector of Indiana for another term, by State Geologist Blatchley, with whom the appointment rests.

Percy E. Barbour has returned from Mexico. After a much needed rest and some professional work in Nevada and California, he will go to Mexico again.

John T. Judd, treasurer of the Tehuantepec Silver Mines Company, has returned

to Boston from an inspection of the company's mines at Tavihe, Oaxaca, Mexico.

George Crerar has resigned as general superintendent of the Takilma Smelting Company, on account of the death of Charles L. Tutt and the closing down of the company's works.

Frederick H. Morley, Denver, Colo., announces that on account of a largely increased practice in Mexico he has now associated with him the firm of Dominian & Smith, mining engineers, of Mexico city.

Robert Thurston Kent has resigned as engineering editor of the *Iron Trade Review*, Cleveland, Ohio, to become managing editor of *Industrial Engineering*, Pittsburgh, a new paper devoted to mechanical engineering subjects.

T. Ohashi, mining engineer and instructor in the Kumamoto technical high school in Japan, has been in New York. He intends to visit a number of mines in the United States for the purpose of studying mining methods and conditions.

George E. Collins is about to retire from the active management of the Argo Mining, Drainage, Transportation and Tunnel Company at Idaho Springs, Colo., and will be succeeded by Roscoe B. Morton. Mr. Collins will remain associated with the company as consulting engineer.

Thomas F. Cole, who has been president of the Oliver Iron Mining Company—the company managing the mining interests of the Steel Corporation in the Lake Superior region—since its organization, has resigned his position in order to devote his time to his other mining and smelting interests.

Cyrus Robinson, consulting engineer, New York, returned home March 17, having extended his visit to Europe into a trip around the world. While in Japan he paid a visit to the copper works at Osaka. He says that while he was prepared to find that the Japanese had up-to-date plants, he was surprised to note their completeness in every detail, comparing favorably with any plants that we have in this country.

Obituary

Henry Biermann died at Monterey, Mexico, March 1, aged 64 years. He was born in Germany, but had been for over 20 years engaged in mining in the northern part of Mexico, and was well known throughout that section. He was president and general manager of the Tamauilpeca Mining Company at Ciudad Victoria.

John Henry Van Dyke, a leader in the early development of Wisconsin mining, pioneer lawyer, and one of the best known public men of the city, died at his home in Milwaukee March 9 at the age of 86 years. Mr. Van Dyke was successively director and vice-president of the Menominee Mining Company, the pioneer of the

Menominee range in Wisconsin and the upper peninsula. In 1887 he was elected president of the Chapin Mining Company, and in the same year, the Pewabic Company was organized with Mr. Van Dyke as vice-president.

William Connell died at Scranton, Penn., March 21, aged 81 years. He was born in Cape Breton, Nova Scotia, and when quite young moved with his parents to Hazleton, Penn. When still a boy he began work in a coal mine, and gradually rose to be mine foreman and superintendent of a local colliery. In 1856 he was placed in charge of the mines of the Susquehanna & Wyoming Valley Railroad and Coal Company, with offices at Scranton. In 1870, when the charter of that corporation lapsed he was enabled to purchase the plant and reorganized under the firm name of William Connell & Co. From this beginning he developed into the largest individual coal operator in the Wyoming region, and later organized and practically owned the Connell Coal Company, which he soon developed into a great coal operating company and later sold out to the Lehigh Valley Coal Company. He accumulated a considerable fortune and was interested in many local enterprises. He was accepted as an authority on coal-trade matters and was often consulted by both miners and operators. He acted as sole arbitrator for the Lehigh Valley Company in settling the claims arising from the Mud Run disaster of Oct. 10, 1888, when 63 persons were killed and 120 injured. Only one case went to court. Mr. Connell was also active as a mediator in the attempted settlement of coal strikes and other local industrial disputes.

Societies and Technical Schools

Mining and Metallurgical Institute of Mexico—A meeting to organize this society has been called, to be held in the city of Mexico in July next. The movement to form the society originated with the Cyanide Club of Durango, and is supported by a number of prominent mining engineers in Mexico. Bernard McDonald is in active charge of the proposed arrangements.

Geological Society of London—At the anniversary meeting Feb. 19, the officers were appointed as follows: President, Prof. W. J. Sollas; vice-presidents, G. W. Lamplugh, H. W. Monckton, Dr. J. J. H. Teall and Prof. W. W. Watts; secretaries, Prof. E. J. Garwood and Dr. A. Smith Woodward; foreign secretary, Sir Archibald Geikie; treasurer, Dr. Anbrey Strahan. The following awards of medals and funds were made: Wollaston medal, H. B. Woodward; Murchison medal, Prof. G. A. J. Cole; Lyell medal, Prof. P. F. Kendall; Bigsby medal, Dr. J. S. Fleet; Prestwich medal, Lady Evans; Wollaston fund, A. J. C. Molyneux; Murchison fund, J. V. Eldsen.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at San Francisco, Butte, Salt Lake City, Denver, Goldfield and Paris

REVIEWS OF IMPORTANT EVENTS

San Francisco

March 19—At a meeting of the creditors of the Northern California Gold Mines Company before the referee in bankruptcy in Marysville last week, it was developed that the concern had debts amounting to \$132,563 and did not even own the Herman mine which it was operating. This mine is at Westville, Placer county, and is still owned by the Herman Mining Company. A. F. Sawhill, of Pittsburg, Penn., president of the bankrupt company said that the stockholders in Pittsburg had no idea that the company had such debts as appeared from the testimony. They had contributed money as called for to meet expenses and the debt in this State had been contracted by those in charge of the mine. In fact the stockholders in Pittsburg were preparing to put up money to pay all the debts when the proceedings were interrupted by the creditors forcing the company into bankruptcy. Expensive machinery had been purchased and the mine was well equipped. It seems that an agent of the company, when offering stock for sale, represented that the company owned the Herman mine and it is hinted that fraud charges may be made before the proceedings are concluded. No trustee in bankruptcy has yet been named as they are waiting for the books to be brought from Pittsburg.

About 300,000 acres have been added to the Tahoe National Forest, contrary to the wishes of numerous mining companies interested in lands now covered by the reserve. It is not yet known in California exactly where the new boundaries are. As originally drawn the new additions to the Tahoe reservation took in old mining ground in Nevada county down to within a few miles of Nevada City. The miners vigorously protested through their Congressional representative, but it is not known definitely whether or not their protests availed.

The new mining camp in Inyo county on the west side of the Argus range, north and east of Mohave and south of Darwin, now has some 300 residents, and numbers of parties are passing through Mohave on their way in. Ballarat is being deserted for the new goldfield. A number of claims have been located and some specimen ore is being shown. A townsite has been platted and a stage line started. The place is called Custer and the stages are running there from siding No. 18. Very little development work has been done thus far, but the ore found on the surface is very promising.

A matter of great moment and great disappointment to the mineowners and managers, of California, is the final passage of the bill regulating the hours of labor in mines, mills, smelting works, etc. The new law provides that the period for employment for all persons in underground mines in search of minerals, whether base or precious, or who are engaged in such underground mines for other purposes, or who are engaged in underground workings for the purpose of tunneling, making excavations, etc., or who are employed in smelters and other institutions for the reduction or refining of ores or metals, shall not exceed eight hours within 24 hours, and the hours of employment in such work shall be consecutive, excluding, however, any intermission of time for meals; provided that in case of emergency where life or property is in imminent danger the period may be for a longer time during the continuance of the emergency.

The law also provides that any person who shall violate any provision of the act, who, as foreman, manager, director, or officer of a corporation, or as the employer or superior officer of any person, small command, persuade or allow any person to violate any provision of the act, shall be guilty of a misdemeanor, and on conviction shall be punished by a fine of not less than \$50 nor more than \$300, or by imprisonment of not more than three months. And the court is given discretion to impose both fine and imprisonment.

In cases where there are strong miner's unions, as in Nevada and Shasta counties, an eight-hour rule prevails already, but in most parts of the State 10 hours' labor is the rule. This new law changes all that as may be noted from the provisions quoted. In smelting works, quartz mills, etc., the change will be particularly noticeable, as it will materially increase present costs of ore reduction. In the Mother Lode section of the State, especially where the mines are being worked on very narrow margins, owing to the low grade of the ore, the effect of this new law will doubtless be the closing down of certain properties. Where high-grade ore is the rule, as in Nevada county, the mines can stand the advance in costs of mining and milling, but in other parts of the State hardship will be worked on mineowners undoubtedly. There have already been increased costs for lumber, supplies, etc. With smaller mines throughout the State

the impending changes will be quite radical and probably a number will cease work altogether.

Another bill which has become a law of the State is more favorable to mineowners. It provides that every person who carries on the business of a pawnbroker or who purchases gold bars, gold quartz, or gold bullion, or mineral containing gold, and who fails to keep a record in a register of the date, duration, amount, etc., of every loan made by him, or an accurate description of the property pledged, or estimated value of the property purchased or the name of residence of the pledgor or seller, or to keep an account of all sales made by him, is guilty of a misdemeanor.

The law also provides that every pawnbroker or person who purchases gold bullion, gold bars, gold quartz, or mineral containing gold, who fails or refuses to produce for inspection, his register or account of sales to any officer holding a warrant, authorizing him to search for personal property, or the order of a committing magistrate directing an officer to inspect such register or account of sale is guilty of a misdemeanor. This law was framed in the interest of mineowners to protect them from "high grading." It is thought they will be better able now to trace specimens, bullion, amalgam, etc., than has been the case. In some mining towns where rich ore is being mined, there have sprung up places where it is easy to dispose of stolen ore, specimen rock, bullion, etc. This law will make it much more difficult for dishonest men to dispose of such stolen property, and make it easier to trace them if they do.

Salt Lake City

March 20—During the week ending March 13 Tintic mines shipped in 20-ton cars: Swansea, 6; Brooklyn, 12; Beck Tunnel, 5; Black Jack, 4; Dragon Iron, 35; Iron Blossom, 15; Colorado, 23. The following mines shipped in 50-ton cars: Centennial Eureka, 45; Eureka Hill, 5; Sioux Consolidated, 14; Ajax, 3; Yankee, 2; Bullion Beck (leasers), 3; Eagle and Blue Bell, 3; May Day, 2; total, 177 cars.

The Park City ore shipments for the week ending March 13 were: Silver King, 993 tons; Daly-West, 362 tons; Daly-Judge, 334 tons; total, 1,689 tons.

Western mining operators are organizing for a strong fight to prevent the proposed reduction in the tariff on the lead contents of ores, from 1½ cents to 1 cent

per pound, as recommended by the Ways and Means committee. A meeting of Colorado, Utah and Idaho operators has been held at Salt Lake City for the purpose of appointing a committee and raising a fund to establish headquarters at Washington where the committee will sit during this session of Congress and plead the cause of the lead industry. [The above meeting was evidently called under a misapprehension. No change in the tariff on the lead content of ores was provided in the proposed bill.]

Butte

March 19—With the recent decline in the price of the copper, there has been no apparent curtailment in the Butte copper production. The Amalgamated mines, with perhaps the exception of the Anaconda, are all sending their regular tonnage to the smelters. Operations at the Anaconda have been somewhat retarded of late by gas, due to fires in the old stopes, on the upper levels.

The number of miners employed today is about two-thirds the number employed two years ago, while the number of tons produced is nearly as large. The shafts have all been sunk to greater depths. The High Ore shaft, through which the water from the Anaconda, Parrot, and North Butte companies, is pumped, has reached a depth of 2800 ft. The Diamond shaft is now also being sunk to that level, and connection will be made with the High Ore shaft.

Denver

March 19—The Livingstone mine, formerly known as the "Potato Patch," at the base of Sugar Loaf hill, in Boulder county, has been reopened after having been idle for three years, and has recovered the rich shoot which made the mine famous when it was discovered about 10 years ago. In addition to a good body of smelting ore, there is a 5-in. streak of sylvanite. The ore is found in the Nyanza, a cross-vein to the main Livingstone dike, near the point of intersection, and in a contact between granite and schist. The first discovery was made in tilling the ground for a potato crop, and from the decomposed outcrop of the vein \$35,000 was recovered with a plough and scraper. The extension of the Nyanza vein is the Ragged Top, and in the lower workings of this group, ore has been struck which is believed to be a continuation of the Nyanza shoot, which, if it maintains its pitch, must enter the Ragged Top ground with depth.

The old Gilpin county camps of Central City and Black Hawk are looking better than for some time past. Several companies are starting up again on company account, and the leasers are doing well. The Newhouse drainage and transportation tunnel will drain and open much new ground under the old mines. The Fifty Mines Company, now owning the Bobtail, Gregory-Fisk and other great producers of

the early day is sending out big reports, and the outlook is promising for a good year.

Goldfield, Nevada

March 16—It is reported that as a result of recent examinations of the mines and prospects of Eldorado cañon, Lincoln county, a custom mill of 30-ton capacity will be erected this spring.

John H. Doyle, special examiner of the U. S. Land Department will take evidence at Reno in land cases in the Olinghouse and other mining districts where it is claimed the Southern Pacific Railroad Company obtained patents to mineral lands by fraudulent methods.

Reports are being circulated of a new district recently discovered north of Lodi and near the Churchill-Nye county line. The district is about one mile wide and six miles long. The formation is porphyry surrounded by granite. As yet the deepest shaft is 100 ft. The ore contains gold.

It is now generally believed that General Manager Mackenzie, of the Goldfield Consolidated, will give up the management of the property, in accordance with an agreement made, when he first assumed charge, that he be allowed to drop the more active duties of management upon the completion of the mill, the opening up of the various orebodies and systematizing the operating department. Mr. Mackenzie will retain the general direction of the property, but will devote the greater portion of his time to the Coalinga oilfields of California, in which he is interested.

The output of the Goldfield district for the week ending March 13 was 6000 tons with an estimated value of \$220,000. Production of the Tonopah mines for week ending March 13 was: Tonopah Mining, 3100 tons; Montana, 780 tons; Belmont, 850 tons; MacNamara, 250 tons; Jim Butler, 200 tons; West End, 135 tons, and Midway, 100 tons; estimated total value, \$140,000.

Despatches from Reno state that orders have been given to have the railroad from Goldfield to Ely surveyed at once. The road may follow the west side of Hot Creek valley, touch Tybo, Helena, Bellehelen and pass close to Revell, opening up a large territory to the north and east of Tonopah and Goldfield. It is hoped that the road will be completed early in 1910. The project is financed by "Borax" Smith and associates.

A hearing has been set for March 29 by the Interstate Commerce Commission on the question of making Reno a terminal point for freight and passenger service. At present all freight shipments from the East billed to Nevada points in the southern part of the State pay freight to Sacramento and back to Reno again, although the goods are carried no farther than Reno. Should Reno be made a terminal point it will mean the saving of thousands of dollars a year to mining camps in the State.

Paris

March 8—The Société des Mines d'Or d'Adieu-Vat et de Bonne-Aventure (French Guiana) has lately published results of the fiscal year ended June 30, 1908. This company is one of the few which work gold lodes in French Guiana. The ore was mainly extracted from the Rocher and Madame lodes and crushed in a 10-stamp mill. Owing to the difficulty of finding labor and also to the bad climatic conditions which prevailed in 1907-8, it was not able to put up the cyanide plant, nor to get sufficient ore to supply 20 stamps. The monthly mill output was 85 metric tons from the Rocher lode averaging 38.2 grams of gold, and 417 metric tons from the Madame lode averaging 15.72 grams of gold. Since July last conditions have improved both as regards the output and the richness of the ore. From July to October the monthly mill output was 160 metric tons from the Rocher lode averaging 60.6 grams of gold, as against 38.2; and 658 metric tons from the Madame lode averaging 16.15 grams. The monthly gold production in this last period was 20,912 grams of gold, worth over \$12,000. Under these conditions the company has been able to meet all expenses with the gold produced. It must be noted it is the first time such a thing has occurred in French Guiana in a deep-mining enterprise.

The Compagnie Coloniale de Dragages Aurifères and the Société Anonyme du Sparvin (Maroni) report that the 5-cu.ft. gold dredges they sent to French Guiana have safely arrived, and that they are now under erection.

A lead and zinc mine is now being developed in France by a company organized in 1908 under the name of Société Minière et Métallurgique de Villemagne, with a capital of 1,500,000 fr., or \$300,000. A concession had been granted a long time ago for an area of 13,000 hectares; but the first owners worked various lodes at the same time and did not obtain satisfactory financial results. The new company will concentrate all its efforts on one lode, where over 40,000 tons of galena ore is now blocked out. A concentrating plant is to be erected with a capacity of 50,000 tons of ore per year. The board includes several leading mining engineers.

The Société Minière et Métallurgique de Penarroja has lately placed a contract for a water-jacket lead furnace. It is the first attempt of this important company to use water-jacket furnaces in place of the old Pertusola type. This water-jacket will measure 44x156 in. at the tuyere level. It will be fitted with 20 tuyeres and be 24 ft. 6 in. high from the ground to the charging platform. Charges will be elevated to the mouth of the furnace by means of skips. Blast will be supplied by a Rateau turbo-blower. The company expects to smelt about 200 metric tons of ore per day in this new furnace.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Arizona

COCHISE COUNTY

Calumet & Arizona—The production in February was 2,393,000 lb., compared to 2,380,000 lb. in January.

Superior & Pittsburg—Production in February was 1,900,000 lb., compared to 2,000,000 lb. in January.

GILA COUNTY

Gibson—This mine at Globe is reported to have been sold to a Boston syndicate.

California

BUTTE COUNTY

Mammoth Channel Gold Mining Company—This company near Magalia has installed a new hoist and is enlarging its shaft to two compartments.

Oro Light and Water Company—The temporary dam built to fill in the break in the Miocene ditch dam, has proved too weak to hold the water and went out the day of completion. A second barrier is to be built. The dam is the intake of the power plants for mines below Magalia.

San Francisco—This mine, near Wyandotte, will shortly be provided with a 10-stamp mill.

EL DORADO COUNTY

Bean Hill—A quantity of mining machinery is being hauled to this mine near Grizzly Flats. Mr. Caldwell is superintendent.

Bug Cañon—The unwatering of the mine is nearly completed.

Prevolcanic—The 700-ft. tunnel is being driven to the gravel channel but work has been interfered with by the rains and seepage water. The development of other gravel claims in the vicinity will depend upon the results obtained in this mine.

KERN COUNTY

Ferris—J. B. Ferris has lately discovered, near Caliente cañon, a deposit containing both tungsten and yellow ochre. Arrangements are being made to work the deposits.

Golden Group—J. B. Ferris, owner, has found tungsten ore of high grade in what he supposed to be worthless material.

MARIPOSA COUNTY

Mount Gaines Consolidated—The 20-stamp mill is in operation. A. R. Maines, of Los Angeles, has become general manager, and W. R. Wardner, of the same place superintendent.

1909 Mining Company—This company, operating the Enterprise mine, near Hornitos is installing a new air compressor. Good ore is being taken from the mine. Fred H. McCall is superintendent.

MONO COUNTY

Masonic District—The snow is impeding operations in this section but some men are working in the Pittsburg-Liberty and work will soon commence on the Tipton.

Standard Consolidated—The working force at this mine, Bodie, is being increased by superintendent W. H. Landers. Mr. Albert Fries has been elected president of the company.

MONTREY COUNTY

Shamrock—This company is at work developing molybdenite claims in Stonewall cañon, between Soledad and the Pinnacles. It has also located other claims in Bryan cañon.

NEVADA COUNTY

Central Consolidated—At this mine, eight miles from Grass Valley, operations have been resumed and the 20-stamp mill started. The plant has received an entire overhauling.

Lecompton—The work of unwatering this mine at Nevada City has been commenced under Superintendent Colt. The mine is owned by A. M. Gilbert, of Santa Barbara. It will take four weeks to drain the mine.

Oustomah—E. H. Wilson, of Nevada City, who is operating several mines in Sierra county, has secured a bond on this property. The mine is already well equipped but some few changes will be made and deep sinking carried on while drifting is being done. Frank M. Evans will be manager of the property.

Ben Franklin—White Brothers, owners, near Grass Valley, continue to take out good ore.

Champion—Tributers are working in virgin ground in some of this company's mines at Nevada City and are taking out good paying ore.

Union Hill—In the Greek ledge, near Grass Valley "jewelry" rock is being mined at present. The ore is being blasted out on the lower levels.

PLACER COUNTY

Rosehide—This quartz property, six miles from Towle, has been sold through

F. L. Bryson to Eastern men. New stamps will be added to the mill and other improvements made. A wagon road will be built, and packing over trails given up.

PLUMAS COUNTY

Nevada Consolidated—J. D. Murray and H. H. Hunter, of Reno, Nev., have arranged for shipment of a 30-stamp mill to this mine in Butte Valley, where they have a large body of low-grade ore.

Shoofly Copper Mine—A long development tunnel is being run on this copper property at Indian Falls under superintendence of G. H. Goodhue. The lode is wide. This property is owned by Seattle and Tacoma people.

SHASTA COUNTY

Western Exploitation Company—A new hoist is being installed at the Milkmaid mine, French Gulch and the shaft will be sunk deeper.

SISKIYOU COUNTY

It is expected that the dredge at Garvey Bar will be remodeled and set at work again. This is 12 miles below Hornbrook. At the Northern California Mining Company's property, Croy's Bar, a dredge will soon be used, the ground having prospected favorably. At Hamburg Bar, on the Klamath, a dredge is being built and will start up in about two months.

Enterprise—In the Lone Jack tunnel a lode of high-grade ore has been struck.

Lewis & Boyer—At this group five miles from Fort Jones, owned by citizens of Colusa, a stamp mill is to be erected.

TRINITY COUNTY

Golden Jubilee—This property at Carrville, owned by Napa county men, was recently closed by attachment. Enough money has now been raised to lift all the attachments and work will be resumed when the snow is all gone.

TUOLUMNE COUNTY

United Gold Mining and Milling Company—A payment has been made on the Tarantula mine near Jacksonville. T. J. Russell is manager. More machinery is to be installed.

United Mines Corporation—The properties in the East belt are still idle, no adjustment having been made between the company and the miners as to their differences.

Colorado

LAKE COUNTY—LEADVILLE

Anona—This company is sinking a shaft on the Gypsy Carbonate claim; another 18 ft. should reach the top of the limestone.

Yak—Resurrection No. 1 has been unwatered and the breast of the tunnel is now in the Fortune territory. It is understood that the management of the tunnel intends to lease the property.

New Monarch—As soon as the sinking of the Cleveland shaft is completed it is the intention of the company to sink the New Monarch shaft several hundred feet deeper.

Granite Tunnel—This bore is now in 407 ft., and a few days ago two veins of ore were encountered. In addition to this there is a body of ore 11 ft. wide on which they have been working for a week. When snow disappears it is the intention of the company to put in machinery.

Fanny Rowlings—For the last week work on this Breece Hill property has been carried on at the lower levels in a body of ore that was recently opened.

Penn—This property is shipping daily 200 tons of an excellent grade of iron ore; 100 tons being sent to the Arkansas valley plant and the other 100 goes to the Salida smelter. The mine is worked by leasers.

OURAY COUNTY

Camp Bird—Under date of March 9, 1909, the directors submit the following report on the working operations of the company for the quarter ending Jan. 31, 1909: Dry ore crushed, 20,301 tons; receipts from bullion sold (including cyanide products), \$435,303; concentrates sold, \$72,220. Working expenses (including development, transportation, and treatment of product), \$152,467; surplus, \$355,065. On Jan. 7, dividend No. 28, of 1s. per share (£41,000) was declared, payable Feb. 6, 1909.

Mine: Number of feet driven, 1105; number of feet in raises and winzes, 223; cubic feet stoped, 124,000.

Production: Of the ore treated during the quarter, about 70 per cent. was withdrawn from the reserves in stopes. The total dry ore broken and in the stopes on Jan. 31, 1909, amounted to 70,653 tons. Everything at the mine and mills has progressed satisfactorily, and a high state of efficiency has been maintained throughout.

TELLER COUNTY

Gold King—Except during labor troubles, this mine is idle the first time in 17 years. It is understood that it will soon be started up under lease. This was the first discovery of ore in the district. It is controlled by Messrs. Lenox and Giddings, of Colorado Springs.

El Paso—The annual meeting of the stockholders was held in Colorado Springs

and the old directors reelected. President Burris' report shows that during last year about \$423,000 dollars worth of ore was shipped by lessees. Announcement has been made that the leases will not be extended beyond May 1. J. W. Nichols, of Cripple Creek has been appointed superintendent of the property.

Prince Albert—The Union Leasing Company, of Cripple Creek, has leased this mine and a contract has been let to Walter Erickson for driving the tunnel 500 feet. The property is situated on the south side of Beacon hill not far from the El Paso. The lessees are also working several other leases. C. G. Jackson, of Cripple Creek, is in charge of the leasing company.

Trilby—It is understood that the mill on this property is to be remodeled. The mill was built a number of months ago and was designed to treat low-grade ores. The property is situated on Bull hill and is controlled by Pittsburg capitalists. A number of leasers are at work on the property, as well as the company. James T. Stewart, of Cripple Creek, is in charge.

Idaho

KOOTENAY COUNTY

Mineral Point—This mine has been added to the list of Cœur d'Alenes shippers. A car of ore sent to the Federal Mining and Smelting Company's sampling works and from there to the smelter netted \$1340.

Idaho Smelting and Refining Company—John Mocine, secretary, has been appointed receiver.

OWYHEE COUNTY

King-Philip—A good lode of silver ore is reported in this mine in Diamond basin.

SHOSHONE COUNTY

Amador Gold and Copper—A temporary injunction has been granted restraining the sale of stock in payment of a 2c. assessment last October. It is claimed that funds have been squandered.

Southern Hercules—E. J. Hunter reports that orders have been placed for equipment to develop 12 silver-lead claims in the Cœur d'Alenes. The main shaft is down to the 200-ft. level, from the bottom of which a drift has been run 60 ft., opening a vein of carbonate ore. A 600-ft. tunnel is to be driven to a point directly under the shaft which will give a depth of 300 feet.

Indiana

CLAY COUNTY

The miners of the Brazil Block district have secured the discharge of Silas Risher, mine-boss of the Rosebud mine, operated by the Vandalia Coal Company, for selling rooms to miners. Four men made affidavit to having purchased rooms from

Risher at prices ranging from \$10 to \$20 per room.

PIKE COUNTY

Notices have been posted at No. 4 mine at Ayreshire that the mine will close down indefinitely on March 25. The closing is caused by overproduction. More than 250 men will be thrown out of work.

VERMILION COUNTY

Clinton Coal Company—This company, operating Crown Hill mines Nos. 1, 2 and 3, west of Clinton, claims to have made a record for steady operation. Mine No. 1 has missed only one day since Feb. 1, and the other two have missed only two days each. The three mines employ 800 men, and the pay-roll averages \$25,000 every two weeks, and have averaged five days each per week since last November. Since the Deering company recently went into the hands of a receiver the Clinton company has been receiving orders for about 2000 tons of coal daily, to go to the United States Steel Corporation at Gary, which had been supplied by the Deering company. The Clinton Coal Company bought 80 acres of coal land from J. H. Bogart, of Clinton, for \$8000 recently. This with 1600 acres recently optioned by the same company, adjoins its present tract.

WARRICK COUNTY

The coal mines are now running from four to five days a week. Domestic trade has been light, owing to the mild winter, but the operators think that when the steam trade opens in April there will be a better demand for southern Indiana coal.

Michigan

COPPER

Winona—Excavation has been begun on the site of the new stamp mill, on the banks of the Sleeping river. The mill will handle the rock from both this company and the King Phillips property.

Ojibway—Sinking close to the 800-ft. level is in progress at No. 2 shaft and as soon as sufficient depth is obtained a crosscut will be started to cut the formation. The crosscut from the level above is passing through a broken trap, indicative of the close proximity to the lode. Sinking is under way at No. 1 shaft toward the same level.

Victoria—Some very encouraging ground in the upper levels has recently been opened. A satisfactory state of mineralization continues in the drift from the 22d level.

Lake—The north drift from the 2d level has again entered the copper bearing formation. This drift passed out of the lode about 40 ft. from the shaft and after continuing it in the same direction for considerable distance again entered it. At the 3d level a crosscut is being driven

westward to cut the formation. This crosscut is now in about 60 feet.

Isle Royal—The new Southern shaft of this company and shafts Nos. 4, 5 and 6 are revealing a satisfactory state of mineralization and with the new hoisting plants in commission at No. 4 and 6 a decided increase in production will be made. President Agassiz of the Calumet & Hecla is asking shareholders for proxies to be voted at the annual meeting, April 7, for the election of a new board of directors, the majority to be chosen from the present directors of the Calumet & Hecla company.

Island—At a meeting recently held at Duluth the following officers and directors were elected: president, Thos. F. Cole; vice-president, Geo. C. Stone; secretary, Fred W. Nichols. Directors, Thos. F. Cole, Geo. C. Stone, F. W. Nichols, G. A. Tomlinson, Henry Nolte, G. G. Barnum, W. Ames, F. W. Heimick and O. J. Larson.

Oneco—Operations will in all probability be resumed during the coming summer. The gratifying results being obtained at the North Baltic Exploration company's land, hold out great encouragement. There is a shaft down 500 ft., but no work of any consequence has been done on the property for several years. The company has \$30,000 in the treasury and 30,000 shares of unissued stock.

Montana

BUTTE DISTRICT

Butte Reduction—An experimental concentrator is in course of construction. It is understood that the ore from the Elm Orlu claim owned and operated by W. A. Clark will be treated here as soon as the concentrator is completed.

Butte Superior—The 1400 level is being prospected with the hope of striking the shoot of copper ore recently opened up on the 1000 level of the Elm Orlu, which adjoins the Butte Superior on the west.

Davis-Doly—A crosscut is being driven on the 1400 level of the Colorado to intersect a body of ore which was lately discovered in diamond drilling.

Copper Eagle—Development work is being pushed on the 350 level. A 50-ton shipment of ore was recently made.

Butte Central Copper Company—This is a new organization with a capital of \$2,500,000 divided into 250,000 shares par value \$10 per share. The company succeeds as the bankrupt Butte Central and Boston Copper Corporation, and owns the Ophir mine in the south portion of the camp. The officers of the new company are: William H. North, president; R. W. Tufts, treasurer and William O. Burns, secretary.

British-Butte—Col. M. H. de Hora leaves for London, March 23, to make report to the stockholders of the company. The dredge which was completed Feb. 1

has been in continuous operation since that date.

SILVER BOW COUNTY

Raven—It is reported that this company is to be reorganized.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Consolidated Rep Top Lease—A new vein has been opened on the 300-ft. level, about 100 ft. west of the vein from which the ore is at present being extracted.

Gold Bar Extension—Work has been resumed by lessees. A hoist has been installed and a crosscut will be run at once for the Gold Bar vein, which is thought to pass within 100 ft. of the shaft.

Great Bend—A winze is being sunk in the ore recently opened on the Diadem Lease. The orebody showing in the winze averages 18 in. of shipping grade. The shaft will be sunk an additional 100 ft. and a crosscut driven to the vein at that depth.

St. Ives—A. A. Codd, president, has developed a plan of reorganization, the new company to be known as the Codd Mines Company. A group of six claims in the Walker river mining district, upon which promising surface showings are found, has been acquired, and it is here that the most extensive development work will be carried on. The new company will be capitalized for 3,000,000 shares, par value \$1 each; stockholders in the leasing company will receive share for share in the new organization, though an assessment of 1c. per share will be made for the purpose of paying old debts and providing a fund for the erection of a small mill to be constructed on the Walker river property.

Goldfield Consolidated—In February the new mill treated 12,858 tons of ore, yielding an average of \$40.75 per ton. The Combination mill treated 2291 tons. The total for both mills was 15,149 tons, yielding \$618,315.

ESMERALDA COUNTY—MINA

Blue Light Copper—A 100-h.p. gasoline hoist has been purchased for this property and is now en route from San Francisco. The shaft, now 720 ft. deep, will be sunk to water-level, which is estimated at 1000 feet.

ESMERALDA COUNTY—HAWTHORNE

Hawthorne Lucky Boy—The lease being worked by Hubbard and associates, of Chicago, has produced upward of \$300,000, and is said still to have ore blocked out above the 300-ft. level. Shipments amount to about 50 tons per day. The lease expires Aug. 1, but the shaft is now being sunk to the 500-ft. level with the expectation of extracting an extra-heavy tonnage before the expiration of the lease. The district, situated about six miles south of Hawthorne on the old

Bodie road, covers an area about six by eight miles in extent, and is well mineralized, with silver and lead together with some copper.

ESMERALDA COUNTY—GOLD MOUNTAIN DISTRICT

Mammoth Mining and Developing Company—This company, with headquarters at Goldfield, recently acquired the old French claims near Old Camp. The property is developed by a shaft 200 ft. deep and several adits. Contracts are to be let for the construction of a mill and a pipe line about three miles in length.

ESMERALDA COUNTY—SILVER PEAK

Pittsburg Silver Peak—The following extract from the annual report shows the net earnings of the company for 1908. The stamp mill was completed in April, but was only in partial operation the first three months of the year, hence the itemized details; January to March, 1908, tons milled, 18,096; bullion receipts, \$116,233; net earnings, \$41,441. April to December, 1908, inclusive, tons milled, 87,574; bullion receipts, \$348,713; operating expenses, \$499,789, and net earnings, \$348,923. The railroad extending from Coaldale to Blair, operated and owned by the company, has been equipped with a gasoline combination car to take the place of the locomotive and is now in successful operation at reduced expense.

ESMERALDA COUNTY—RAWHIDE

Marigold Lease—Ore is being extracted from the north drift of the 130-ft. level. The last shipment to the Hazen sampler netted \$198.30 per ton. More care is being taken in the sorting of the present shipment.

Mint Lease—The orebody recently encountered on the 300-ft. level shows no signs of decreasing value although drifted on 80 ft. to the north and 70 ft. south. The vein varies from 4 to 6 ft. in width.

NYE COUNTY—ROUND MOUNTAIN

Round Mountain Mining Company—Material for the addition to the mill is now being hauled from Tonopah to Round Mountain.

NYE COUNTY—IONE

Grand View—J. O. Kinney, president, is now in the east negotiating the purchase of a hoist and a five-stamp mill. The company owns four claims, though development work has been confined chiefly to the Grand View lode.

WHITE PINE COUNTY

Nevada Consolidated—In the first half of March this company mined upward of 2000 tons of ore per day. Production in January was 1,451,000 lb.; February, 1,686,000.

Chamberland-Ely—January production, 1,094,218 lb.; February, 1,233,492.

New Mexico

SIERRA COUNTY

County Seat—The legislature passed a bill making Cutler the county seat instead of Hillsboro. The bill also provides that that portion of Socorro county extending south along the eastern boundary of Sierra and west of Lincoln and Otero counties shall be taken into Sierra county.

SOCORRO COUNTY

Kelly Mine—Monthly shipments aggregate 15 to 20 cars zinc carbonate.

Graphic Group—The Sherwin-Williams Company is shipping 10 to 15 cars of ore per month. Jos. Brown, of Kelly, New Mexico, is in charge of the mine.

Mistletoe and Magdalena Tunnel—Machinery is arriving for a 50-ton dry concentrator. The ore will be sized by impact screens and concentrated on pneumatic tables. W. F. Gordon is superintendent.

Mill Cañon Copper—George Keith is manager. The company recently purchased the Wheel of Fortune group, 12 miles south of Kelly.

Old Soldier—Mike Wolf, manager and principal owner, recently shipped two cars of lead-silver-copper ore, which gave good returns.

South Dakota

For some time past there has been under consideration the building of a modern smelter in the Black hills. The first definite step in that direction was the leasing of the Hester A and Rainbow claims in Galena on March 16. The ore is refractory silicious material carrying pyrite, and is suitable for matte smelting. The lease runs for two years, with the provision that the building of the smelter shall begin within four months and that it shall be in operation within eight months from date. Negotiations have been entered upon for the Richmond ground, under lease till the latter part of this year to the Branch Mint Operating Company.

CUSTER COUNTY

An effort is being made to resume the mining of lithographic stone near Custer, where the Black Hills Porcelain, Clay and Marble Company holds several claims as yet unpatented.

LAWRENCE COUNTY

Ruby Mining Company—This company, capitalized at \$1,000,000, has recently been formed to work a group of claims in the Tinton district. An 80-h.p. boiler and engine are being installed for development purposes.

Gold Eagle—Superintendent Keller is sinking a shaft to go 200 ft., near Maitland.

Golden Girl—Work has been commenced by A. M. Masters, of Jacksonville, Ill., on a wide ledge of ore.

Johnston—Sinking on Iron creek will soon be commenced by Thomas Johnston, the owner. The 40-ft. shaft will be sunk to a depth of 100 ft. New machinery is now being installed on the property.

Tinton—Superintendent Carnahan has succeeded Superintendent Noakes, of Chicago, and the mill will now undergo still further changes before operations begin this spring.

PENNINGTON COUNTY

Balkan—This company, which has been operating a five-stamp mill in the Rochford district, is adding five more stamps to its equipment.

Utah

JUAB COUNTY

Plutus—Ore of fair grade has been encountered in drifting to the north at a depth of 200 ft.

Zuma—Work will be resumed on the lower levels during the coming month.

Swansea Extension—The shaft is 140 ft. below the tunnel level. Drifting to the north and south is in progress and the shaft will be sunk an additional 100 feet.

Bullock—A crosscut is being driven west from the 210-ft. level.

Tintic Central—The shaft has a depth of 220 ft. and is in limestone. A hoisting plant has been ordered and power will be obtained from the Telluride Power Company. The property adjoins the Iron Blossom.

Mammoth—A shipment of 30 tons of high-grade ore was recently made, being consigned to Irvington, N. J.

East Tintic Consolidated—A depth of 75 ft. has now been reached by shaft.

Tintic Central—The shaft is down 235 ft. and a drift to the east will be started toward the south extension of the Iron Blossom vein.

Victor—Work is in progress on a body of copper ore on the 800-ft. level.

Murray Hill—Col. T. P. Murray, of Los Angeles, has taken an option on the East Humburg, Comstock, Knight, and Jack Fraction north of the Yankee Consolidated. The company will be called the Murray Hill Mining Company.

Tintic Empire—A contract has been let for sinking 100 ft. of double compartment shaft.

Wicklow—A tunnel is now in 427 ft and a contract will be let for additional work at once.

May Day—The shaft is now down 945

ft., and is to be continued until a depth of 1000 ft. is reached.

Iron Blossom—Jesse Knight states that dividends are to be commenced in April and claims to now have a larger body of high-grade ore than was ever exposed at one time in the Colorado. Twelve cars recently marketed assayed 40 per cent. lead, 113 oz. silver and \$13 gold. The property is shipping 100 tons per day to the Tintic smelter.

SALT LAKE COUNTY

Peruvian—Ore has been struck on the main level. While no assays have been made it is of a shipping grade and carries copper, lead and silver.

Cardiff—On the drain tunnel level, 18 in. of shipping ore carrying good values in copper, lead and silver has been found, besides 8 ft. of low-grade rock.

Columbus Consolidated—On the 400-ft. level, west of the shaft, the management has explored an orebody for a length of 150 ft. with a width in places of 15 to 20 ft. The rock runs well in silver and copper. One carload per day is being marketed.

Boston Consolidated—February production, 2930 tons sulphide; 129,000 lb. copper delivered; 35,000 tons wet-milled, 32,000 tons dry; 1575 tons dry concentrates, yielding 711,000 lb. copper.

Washington

FERRY COUNTY—REPUBLIC

New Republic—This mine is reported to be employing 50 men and shipping ore regularly to the Granby and Tacoma smelters. A car of new mine equipment, including a hoist, air compressor, machine drills and drill sharpener was unloaded last week.

San Poil-Republic—This newly organized smelting company proposes to begin constructing a smelter near Republic. The officers are R. J. Howard, Spokane, president; W. B. Parker, Spokane, vice-president; R. J. Leonard, Republic, secretary. The company is being financed by Spokane and Seattle capitalists.

FERRY COUNTY—KELLER

Byrne—Development work has opened up a new silver-bearing vein. Dr. P. S. Byrne and J. R. Cassin, of Spokane, and R. L. Boyle, president of the Keller & Indiana Consolidated Smelting Company, are the principal owners.

Canada

BRITISH COLUMBIA—KAMLOOPS

Iron Mask—This mine, owned in England, has been bonded by United States operators, who have about 20 men employed in its further development. Other

mineral claims in the camp are under option to American capitalists, who are arranging to have them well prospected.

BRITISH COLUMBIA—AINSWORTH DIVISION

Wagner Group—D. C. Corbin, of Spokane, has, it is announced, bonded the Wagner group of mineral claims situated in the northern part of Ainsworth mining division, on the Duncan river slope of the Selkirk range. This has long been known as the most prominent mining property in that part of the country, but owing to its distance from transportation facilities it has not been extensively developed. It was described by W. A. Carlisle (then provincial mineralogist) in his annual report for 1897 as being "the highest mine in the province, elevation 8200 ft." It is in the "great lime dike" of the Selkirks. R. W. Brock, in the summary report of the Geological Survey of Canada for 1904, stated that the ore is cubical galena with some pyrite and gray copper. Two veins of ore have been opened on the property.

BRITISH COLUMBIA—CROW'S NEST PASS

D. C. Corbin, of Spokane, Wash., who last year constructed 14 miles of railway, from McGillivray, on the Canadian Pacific Crow's Nest branch to the Corbin Coal and Coke Company's coal mine, has obtained the necessary authority from the provincial legislature of British Columbia for the extension of his company's railway 40 miles south to the International boundary.

Queen Victoria—This mine, on which an option was held and recently relinquished by New York men, has been bonded by the Consolidated Mining and Smelting Company of Canada, Ltd., which owns other mines in Kootenay and the smelting works at Trail. The mine is situated about eight miles from Nelson and 37 miles from the Trail smelter, with which there is railway connection. There is a large body of low-grade copper ore in the mine.

BRITISH COLUMBIA—EAST KOOTENAY

R. L. Broadbent, of the Geological Survey of Canada, who was in charge of the Canadian mineral exhibits at the World's Fair, St. Louis, in 1894; at Liege, Belgium, in 1905; at Milan, Italy, in 1906, and at Christchurch, New Zealand, in 1907, has obtained, for inclusion in the British Columbia display at the Alaska-Yukon-Pacific Exposition, representative samples of coal from the Crow's Nest Pass coal mines, and specimens of lead and silver-lead ores from the North Star, Sullivan, and St. Eugene mines, all in Fort Steele mining division, East Kootenay. Samples of various grades of lead-silver concentrates have been obtained from the St. Eugene mill as well. Mr. Broadbent is continuing his work in West Kootenay.

BRITISH COLUMBIA—SLOCAN

Emily Edith—Another shoot of high-grade silver-lead ore has been found in

this mine, which is being worked in conjunction with the adjoining Standard mine, under the direction of one of the owners of the latter, George H. Aylard, of New Denver, B. C. The Emily Edith has been opened by six adits and about 9000 ft. of underground development done. The Standard last year shipped 1250 tons of first-class ore, containing approximately 106,000 oz. silver and 1,600,000 lb. lead. A similar quantity of milling ore was placed on the dump to await provision of plant for concentrating.

BRITISH COLUMBIA—VICTORIA

Mr. Orr, manager of the exhibition association of Toronto, Ontario, has interviewed the provincial government with the object of inducing it to make suitable display; thoroughly representative of the mining industry of British Columbia, at the Toronto fair, which is regarded as Canada's national annual exhibition.

The Consolidated Mining and Smelting Company of Canada, Ltd., made a shipment of pig lead from its lead refinery at Trail to Australia by the steamer sailing from Victoria on Feb. 26.

The output of coal from the Coast district of British Columbia in 1908 was 1,229,328 tons.

SASKATCHEWAN

The "Annual Report of the Department of Public Works of the Province of Saskatchewan for the Financial Year 1907-08" has recently been made public. It includes the following statistics, relating to the coal-mining industry of the province: During the financial year ended Feb. 29, 1908, there were 19 coal mines in operation, which produced in the 12 months 189,428 tons. There were 232 persons employed inside the mines and 81 outside. Only one nonfatal and two fatal accidents were reported. There were seven new mines opened in the course of the year, and one mine was abandoned. In Saskatchewan, coal mining is only in its beginning; gradual development to operations on a larger scale is in progress.

ONTARIO—COBALT DISTRICT

Temiskaming—The financial statement shows that on Jan. 31 the company had cash on hand and ore in transit valued at \$122,761. The output during the fiscal year was 831 tons of ore, which produced 1,026,285 oz. silver of the net value of \$494,211. The cost of production was 8.4c. per oz. There were 16,000 tons on the dump of an estimated value of \$250,000 to be concentrated.

ONTARIO—PORT ARTHUR DISTRICT

Hanson Consolidated—Active operations have been resumed and prospects are improved by increased railway facilities. Herbert Shear is in charge of the property and reports three carloads of silver ore ready for shipment to the smelters.

Mexico

CHIHUAHUA

Parral Output—Production for the week ending March 12 was 10,010 tons, of which 6550 tons were locally treated. Revised figures show the February output to have been approximately 38,500 tons.

Calamine Mining Company—This company was lately organized on the basis of the Seawell-Robinson-Terrazas holdings in Los Lamentos district, reached from Ahumada on the Mexican Central railway line. G. V. B. Levings, of Parral, is president, and George B. Squire, secretary and manager. Zinc ore is being marketed in Kansas, and lead ore is shipped to the Monterrey smelter.

San Toy—The report for the year 1908 contains the following items: Sales of ore, \$547,209; net returns from ore, \$312,961; mining costs, \$245,921; net mining profit, \$67,040; surplus for year, \$52,850; previous surplus, \$217,412; profit and loss deficit on Dec. 31, 1908, \$164,592.

Capitanena—P. H. Cooper is manager of this and the San Diego mines at Santa Barbara, Gustave Reich having resigned.

Potosi—This Santa Eulalia company is said to be planning the erection of a dry-concentration plant for treating a large tonnage of low-grade zinc ore.

Batopilas—The February output was 300 bars of silver bullion, bringing the total of the first two months of the year to more than 500,000 pesos. The March production will probably be in excess of the previous month.

Hearst Oil Syndicate—Drilling operations have been resumed in the eastern part of the State. A third well has been started near La Mula. J. G. Fallonsbee has general charge of the company's local affairs and L. A. Smith is in direct charge of the drilling work.

Moctezuma—Promising copper properties are under exploitation in this unexplored section in the northern part of the state. The main operations are by the Chihuahua Copper Company, of which James Parker, of El Paso, is manager. Shipments of ore running 9 per cent copper in car lots have been sent out during the past few months. The region is easy of access by wagon roads from Moctezuma station on the Mexican Central Railway.

SONORA

Greene Gold-Silver—The Humboldt Exploration Company, encouraged by the liberal response of the Greene Gold-Silver Company's stockholders to its proposal, will extend time for the exchange of stock to April 1 next.

Cieneguita Copper—A railroad company has been incorporated to construct a narrow-gauge railroad from Tonichi in the Yaqui valley to the company's mines, 40 miles distant in the Sahuaripa district.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, March 24—The coal trade in the West has shown a little improvement, some spring demand for steam coal being noted; and many industries are apparently needing more fuel than they have for some time. Production is still restricted at many mines and supplies are being fairly well regulated to demand.

In the East the bituminous trade is improving a little, but can still be called quiet. Dealers, however, are hopeful of an early revival, if not of a rapid one.

The anthracite question is still unsolved. There are all sorts of reports about the disposition of the miners to accept the terms which the operators have offered. Nothing definite can be said until after the meeting of the miners' convention. That convention assembled last evening in Scranton, Penn., but it may be two or three days before any final action is taken. The general belief in the anthracite region is that the union men will vote for a strike, but that the majority of the non-union miners would prefer to have no change. The latest statement is that all other demands will be abandoned, provided there is full recognition of the union—that is, a surrender of the open shop.

Proposed Coke Consolidation—A plan has been proposed for the consolidation of a number of independent coke plants in the Connellsville region in Pennsylvania. It is proposed to unite in one company all the plants not controlled by the H. C. Frick Coke Company. Options are said to have been obtained on a number of properties. J. V. Boileau, of Pittsburg, represents the promoters of the scheme.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburg and Erie, year to March 13, short tons:

	1908.	1909.	Changes.
Anthracite.....	1,062,936	952,392	D. 100,544
Bituminous.....	6,661,256	6,850,177	I. 288,921
Coke.....	1,448,929	1,994,648	I. 545,619

Total..... 9,063,121 9,797,117 I. 733,996

Shipments of coal by water from Seattle and Tacoma, Wash., in January were 58,356 tons in 1908 and 26,829 tons in 1909; a decrease of 31,527 tons.

Coal passing through lock No. 3 on the Monongahela river in January was 778,400 tons in 1908, and 763,120 in 1909; a decrease of 15,280 tons.

Coal receipts at St. Louis in January were 666,810 tons in 1908, and 621,647 in 1909; a decrease of 45,163 tons.

Chief Mine Inspector Flynn reports coal production in Alabama in 1908 as follows: Jefferson county, 5,254,817 short tons; Walker, 2,522,862; Bibb, 1,180,228; Tuscaloosa, 714,015; Shelby, 369,344; other counties, 433,325; estimate on small mines not yet reported, 500,000; total, 10,974,591 tons. This is a decrease, as compared with 1907, of 3,443,272 tons, or 23.9 per cent.

Bituminous coal and coke shipments, Pennsylvania and West Virginia, month of January, short tons:

	Coal.	Coke.	Total.
Balt. & Ohio.....	1,666,537	353,592	2,020,129
Buff., Roch. & Pitts.	450,988	35,735	486,723
Buff. & Susqueh'ua	125,676	22,200	147,876
Penn. Lines, N. Y. C.	703,004	8,308	711,312
Pitts. & L. Erie.....	562,526	344,566	907,192
Norfolk & Western.	946,025	226,286	1,172,311
Total.....	4,465,366	969,795	5,435,151
Total, 1908.....	4,062,516	568,429	4,630,945

Total increase this year 834,207 tons, or 18.1 per cent. In addition to the above, the Baltimore & Ohio carried 78,452 tons of anthracite in 1908 and 90,099 in 1909; increase, 11,647 tons.

Coal tonnage of railroads in Ohio Coal Traffic Association, month of January, short tons:

	1908.	1909.	Changes.
Hocking Valley.....	186,676	244,945	I. 59,369

Norfolk.....	236,004	236,004	472,008	14.3
Total.....	1,578,297	1,777,927	3,356,224	100.0
Total, 1908.	1,350,128	1,928,460	3,478,588	

Total decrease this year was 122,364 tons, or 3.5 per cent. New York includes all the New York harbor shipping ports.

Coal receipts at Boston, two months ended Feb. 28, reported by Chamber of Commerce:

	1908.	1909.	Changes.
Anthracite.....	241,755	192,860	D. 48,895
Bituminous.....	493,503	449,332	D. 44,171
Total domestic.....	735,258	642,192	D. 93,066
Foreign.....	97,602	48,923	D. 48,679
Total.....	832,860	691,115	D. 141,745

The foreign coal comes chiefly from Nova Scotia. Total decrease this year, 17 per cent.

New York

ANTHRACITE

March 24—The anthracite trade shows no material change. Domestic sizes continue quiet and strike possibilities have not had any effect, as consumers are confident of the ability of the producers to carry them over any period of suspension that is probable. Steam sizes are in demand for the same reason as noted last week. The April discount on prepared sizes is still in suspense.

The list prices for prepared sizes are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points. Dealers and agents are getting from 10 to 20c. per ton advance on pea and No. 1 buckwheat.

BITUMINOUS

The soft-coal market shows little or no change. Contract talk continues, but business is closed slowly. The far East is waking up a little and making some inquiries, while trade along the Sound is gradually improving. All-rail trade holds its own very well, but without much increase. Transportation and car supply are causing no complaints.

New York harbor is still rather irregular, but buying is not quite so unsteady as it has been. Prices continue \$2.40@2.50 per ton, f.o.b. harbor ports, for good steam coal; with \$2.20@2.30 for lower grades.

The Coastwise trade is still poor and some owners are talking of laying up their boats rather than to keep them at work at current rates. These rates are unchanged from last week.

Birmingham

March 22—The coal trade in Alabama is quiet. The production is to be farther reduced, if there is no improvement in the demand. There is a large quantity of coke stacked up for any emergency. Some of the larger consumers of coal are holding back and mines are only being operated to meet the demands. The railroads are feeling the falling off in business. There is a gloomy feeling in coal circles in this section.

Chicago

March 23—The coal trade continues firm, but unmarked by special features. Shipments are well held down to prospective needs and the demand has not fallen off for any kind. Steam coals continue about even; domestics are in light demand, the average consumer delaying purchases of anthracite to April and his consumption of bituminous being slack because of the weather.

The tendency is to adjustment of the market to spring conditions, lump falling off and slack coal advancing. In anthracite the small sizes are in much stronger demand. Contract making, in general, is slack, the disposition of consumers being to hold off, in hopes of favorable open-market conditions.

Illinois and Indiana bituminous bring \$1.75@2.40 for lump and egg, \$1.65@1.75 for run-of-mine and \$1.25@1.55 for screenings.

Eastern coals are considerably stronger, demurrage coal being practically off the market. Smokeless lump and egg are not so strong as run-of-mine, which is in less supply and brings \$3.05@3.15 for Pocahontas and New River. Hocking is firm at \$3@3.15 and Youghiogheny also at \$3.15 for ¾-in. gas. Pittsburg No. 8 is a trifle weak at \$2.75@2.85 for ¾-in. lump.

Cleveland

March 23—Domestic trade is down and out for the present. Dealers are cleaning up their yards and preparing for next season. A few sales of Massillon lump at \$3.25 constitute the record. Steam coals are looking up a little, especially slack, but prices are low. Lake trade has hardly started yet, and looks as if it would have a late beginning this year.

Indianapolis

March 23—At the annual meeting of the Indiana Coal Operators' Association held in Terre Haute March 20, the following officers were elected: President, J. S. Kolsem; vice-president, Hugh Shirkle; secretary, Philip Penna. The new directors elected are Homer Talley, M. M. Gould, John McCadden, Val. Martin and George Nester.

The principal topic considered at the meeting was the supposed intention upon the part of the Steel Corporation to gain control of the coalfields of Vermilion county, Ind., and Vermilion county, Ill., nearest the Gary plant. The plan is believed to be to profit by the impairment of the Deering company, which owns about 30 mines in that territory. It is the policy of the company to get hold of as much coal land as possible for the future. This mission, however, is regarded by Indiana operators with some concern. Some important deals are almost sure to be made

in the securing of coal mines and coal lands in Indiana during the present year.

Pittsburg

March 23—The placing of several important contracts this week infused new life into the coal trade and the outlook is somewhat better than it has been for some time. The Crucible Steel Company of America yesterday closed with the Pittsburg Coal Company and the Monongahela River Coal and Coke Company for 500,000 tons of mine-run coal for deliveries running through the year. The Pittsburg & Westmoreland Coal Company closed contracts for 900,000 tons of coal for shipment to the northwestern markets and is among the first of the lake shippers to book orders. This company also took a contract for 100,000 tons of crushed coal for the Montreal Heat, Light and Power Company, Montreal, Canada. The coal is to be crushed at the mine in order to take advantage of the low duty of 15c. per ton.

Prices remain on the basis of \$1.15 per ton for mine-run coal at the mine, and slack is quoted at 65@70c. Less than 50 per cent. of production is coming out, except at the river mines, which are running full. A number of tows of empty coal boats and barges arrived this week from lower ports and were sent up to the pools.

Connellsville Coke—Conditions in the coke trade do not show much improvement, but the outlook seems a trifle better. The Pickands-Magee Coke Company has received an order from the Hamilton Steel and Iron Company, Hamilton, Ont., to increase its regular shipments from 300 tons to 600 tons per day, and to add to cars daily until further notice. The same company began this week to ship an order of 4000 tons of smelter coke to Tampico, Mexico. The coke is being sent to Baltimore where it is being loaded. The current quotation for smelter coke is \$1.40 per ton at ovens. Spot furnace coke continues to sell at around \$1.50, and on contract at \$1.60@1.75. Foundry coke is quoted at \$1.90@2.15 for spot and on contract.

The *Courier* gives coke production in both regions at 252,617 tons. The shipments were 8972 cars, as follows: To Pittsburg district, 3106; to points west of Pittsburg, 5115; to points east of Connellsville, 751 cars.

Foreign Coal Trade

British Coal Production—A preliminary statement gives the production of coal in Great Britain in 1908 at 251,506,379 long tons; a decrease of 6,306,473 tons, or 2.4 per cent. from the previous year.

British Coal Exports—Exports of fuel from Great Britain, with fuel sent abroad

for use of steamers in foreign trade, two months ended Feb. 28, long tons:

	1908.	1909.	Changes.
Coal	9,360,445	8,688,934	D. 671,511
Coke	191,762	166,056	D. 25,707
Briquettes	269,298	234,938	D. 24,360
Total	9,811,505	9,089,927	D. 721,578
Steamer coal	3,147,257	2,921,409	D. 225,848
Total	12,958,762	12,011,336	D. 947,426

This shows a total decrease of 7.3 per cent. in coal sold for use beyond the limits of the United Kingdom.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on March 13: Best Welsh steam, \$3.36; seconds, \$3.24; thirds, \$3.12; dry coals, \$3.48; best Monmouthshire, \$3.66; seconds, \$2.94; best small steam, \$2.16; seconds, \$1.92. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, March 24—There is some improvement in the iron and steel trades generally, with a rather better feeling and a more confident tone to the market. The proposed tariff reductions have had really very little effect, partly because they had been discounted, and partly because people generally understand that their effect will not be to bring about any considerable imports, though they may tend to limit increases in price in case of an improvement in business.

In pig iron, furnaces seem to be rather looking for business and, therefore, in accommodating mood about prices. Some orders are reported taken at rather low figures and southern makers have been shading freely, orders being reported placed on a basis of \$11 for No. 2 foundry at Birmingham. Northern makers appear to be a little in doubt whether to meet these quotations, especially as no decision has been reached on the prices for Lake ore for the coming season.

In finished material orders are being placed rather freely for structural steel and a number of bridge and building contracts have been closed. It is reported that some orders have been taken as low as 7.10c. at mill for this material. The railroads are not coming forward with rail orders, although bridge contracts are coming in more freely. Two or three large contracts for trolley rails are under discussion.

The Cambria Steel Company has announced a cut of 10 per cent. in wages, and other companies are preparing to follow. The Steel Corporation, however, has made no announcement of its intentions in this respect so far.

Proposed Steel Combination—Reports have been in the air of the consolidation of a number of independent steel plants into one large company. These reports, however, have been denied by representa-

tives of the Jones & Laughlin, the Pennsylvania Steel, the Cambria Steel, the Republic Iron and Steel and other companies which have been mentioned in connection with these rumors.

Baltimore

March 23—Exports for the week included 807,283 lb. zinc dross and 2,273,700 lb. steel billets to Liverpool. Imports included 10,711 slabs of spelter and 842 tons manganese ore from Rotterdam; 3393 tons pyrites from Spain; 6400 tons iron ore from Cuba.

Birmingham

March 22—While there is some little selling of pig iron going on in the Birmingham district, it is admitted that but few, if any, of the companies are selling their make. The quotations are still weak, some of the companies selling the product under \$12 per ton, No. 2 foundry, a report having it that \$11.50 is not the lowest price, \$11 being accepted. The make has been reduced a little lately, one or two furnaces having been blown out. The shipment of pig iron continues good, on business booked before the recent depression set in.

The Bessemer rolling mills of the Tennessee Coal, Iron and Railroad Company have resumed operation after a shutdown of a few weeks. Statements continue to be circulated that the steel plant of the Tennessee company at Ensley will be shut down for repairs and to wait an improvement in general conditions. There has been some selling of steel rails recently from this plant and shipments have been healthy. F. H. Crockard, vice-president of the company, who recently returned from a trip to New York when seen, declined to make any statement.

Chicago

March 23—Pig iron continues dull. Melters are still buying only for immediate needs; they will not contract generally for the future. In consequence, prices are weak, and \$12 Birmingham (\$16.35 Chicago) represents the basic price of Southern, while \$11.50 is said to obtain on such few contracts as are possible. Northern No. 2 is at \$16.50, with the demand steadier than for Southern.

Coke shows the pig-iron depression, the best Connellsville selling as low as \$4.75. In iron and steel products there is yet no heavy buying generally, though a generally better market probably exists.

Cleveland

March 23—Movement of ore from the docks is increasing and March will record fair shipments to furnaces. More inquiries are coming in about prices for the

coming season, but nothing definite has been done.

Pig iron is quiet, but some local orders have been placed at about \$15.75, Cleveland, for No. 2 foundry.

In finished material a large shipbuilding order has been placed, which will require a good quantity of plates and shapes. Orders for building and bridge material are coming in quite freely.

Philadelphia

March 24—The pig-iron market is weak and dull, and little business has been done for several days. The outlook is discouraging and makers are not inclined to take a hopeful view of the possibilities for the coming 30 days. Local foundries and other buyers are doing very little, but it is reported that outside consumers have taken considerable iron for early delivery. Competition of Southern makers is more keenly felt this week than for some time. Further shadings have been made in several well known brands of Southern iron, but up to this afternoon leading makers here have not followed suit. Basic iron is the only material that holds its own.

Steel Billets—Small lots for immediate use have been contracted for in this territory for early deliveries said to be at \$1 per ton below prices named two weeks ago.

Bars—It is rumored that a further shading has been made by one or two mills on refined bar on a basis of 1.40 cents.

Sheets—Makers claim to be booking a fair amount of business.

Pipes and Tubes—Activity prevails in steel pipe and cast-iron pipe, the effect of which is reflected upon this market.

Plates—The rumor of curtailment has no relation to the plate mills. Two or three large orders have come to Pennsylvania mills. The outlook for the steel-plate makers is bright.

Structural Material—It is understood that structural material has been shaded once more, though the fact is not admitted by the manufacturers who claim that the base price of 1.25 to 1.30 will not be departed from.

Scrap—The scrap dealers are obliged to hold everything they have and they are slow to purchase or contract for new supplies except on very favorable terms. Railroads are refusing to sell scrap at present prices. Heavy cast scrap has been called for in small lots, and two or three lots of old car wheels have been sold. The yards are pretty full of material and will be fuller yet.

Pittsburg

March 23—Outside of sheets and tinplate little new business of consequence developed during the week. The American Sheet and Tin Plate Company has started the Greer works, at New Castle, Penn., 20 mills, La Belle works, Wheeling,

W. Va., 10 mills, and the Pittsburg works, New Kensington, Penn., 8 mills, increasing the number of active mills to 202, and leaving but one of its plants, the United States at Demmler, Penn., 11 mills, idle; this plant likely will be going next week. The company also has four plants with a total of 29 mills that have not been operated for over two years and will be put on the active list only in the event of extremely prosperous conditions. The company has increased its sheet capacity to 105 mills and now has but 71 idle mills, some of which may be started during the coming week. The independent tinplate mills are operating about the same as before the stiff cut was made in prices and it is reported that most of them are getting satisfactory concessions from steel mills on tinplate bars.

The National Tube Company is operating its plants at around 60 per cent. but in the Pittsburg district the operations are close to 90 per cent. A number of large orders are pending. The Oklahoma Natural Gas Company is figuring on placing an order for 300 miles of 16-in. line pipe, the Pure Oil Company, of Illinois, for 400 miles of 8-in. pipe and the Kansas Natural Gas Company 60 miles of 16-in. pipe.

Officials of the American Steel and Wire Company and the Pittsburg Steel Company, the largest independent wire producer, declare that prices remain the same and no change is contemplated at present. They admit that orders are not coming in as freely as expected. It is rumored, however, that a general readjustment in prices must be made before the jobbers can be induced to buy.

The Carnegie Steel Company is operating its three rail mills to only 25 per cent. of capacity. The mills are busy on structural shapes, a number of important specifications having been received. In structural material it is reported that contracts have been taken as low as 1.10c. at mill.

Pig Iron—The market continues dull and low prices are still being quoted. Pig-iron quotations this week are purely nominal as follows: Standard bessemer, \$14.75 @15; malleable bessemer, \$14.50@14.75; basic and No. 2 foundry, \$14.50, and gray forge, \$13.50, all at Valley furnaces.

Steel—Considerable shading of billets is reported but the large producers are holding to \$23, Pittsburg. Sheet and tinplate bars are quoted at \$25.50 delivered at Youngstown, New Castle, Bellaire, Wheeling, McKeesport and adjacent points, but are said to have been sold within the past few days at a lower price. Merchant-steel bars are still quoted at 1.20c. and plates at 1.40 cents.

Sheets—The market shows considerable improvement since the cut in prices. Prices remain at 2.30c. for black and 3.30c. for galvanized sheets, No. 28 gage.

Ferro-Manganese—Prices remain at \$41 @41.50, seaboard, or \$43@43.50, Pittsburg.

Metal Market

New York, March 24—Changes have not been material, but there seems to be a slightly better tone to the markets in several directions.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Feb. 1909..	\$ 8,860,814	\$ 3,576,413	Exp. \$5,284,401
" 1908..	1,967,597	2,847,133	Imp. 879,536
Year 1909..	16,736,170	6,996,696	Exp. 9,739,574
" 1908..	2,411,797	13,646,617	Imp. 11,234,820
Silver:			
Feb. 1909..	4,862,649	3,508,881	Exp. 1,353,668
" 1908..	4,108,774	3,461,755	" 637,019
Year 1909..	9,394,643	7,178,633	" 2,221,020
" 1908..	8,206,918	7,073,629	" 1,133,289

Exports from the port of New York, week ended March 20: Gold, \$6,850,985, principally to Argentina and London; silver, \$460,985, chiefly to London. Imports: Gold, \$623,554, from France and South America; silver, \$55,435, from the West Indies and Mexico.

Gold—The price of bar gold continues 77s. 4d. per oz. in the open market in London; American eagles are in some demand and are quoted 1d. higher at 76s. 5d. per oz. In New York a total of \$8,000,000 in gold has been taken for export during the week and the movement apparently is not yet at an end.

Platinum—Business is quiet and there has been no change in prices. Dealers quote \$23@24 per oz. for refined platinum, \$26 for hard metal and \$19@21 for scrap.

Our St. Petersburg correspondent reports, under date of March 4, that the market shows a stronger tendency. At Ekaterinburg quotations are 5@5.05 rubles per zolotnik, for crude platinum, 83 per cent.; at St. Petersburg, 20,300@20,500 rubles per pood. These prices are equivalent to \$18.99 and \$19.99 per ounce, average, respectively.

Silver—The market has remained fairly steady, with small fluctuations. Pressure from China to sell is much less, and the Indian hazards are regular buyers; but demand has not been sufficient to advance the market. No great change in prices is looked for in the immediate future.

SILVER AND STERLING EXCHANGE

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125¢ below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—The lower prices established last week led to more active interest on the part of European buyers, who were stimulated also by speculation for the rise in the standard market. Some fairly large quantities were thus sold for export. This brought out some large buying orders which had been pending from domestic manufacturers, and a firmer tendency developed in consequence. Altogether a good volume of business was done both for foreign and domestic account, both in Lake and electrolytic, but chiefly the latter. There was a good demand for casting copper in the early part of the week, which for a time sold practically on the same terms as electrolytic. Lake copper appears to be in a strong position, probably because of the centralization in the market for this quality, and some sales of fancy brands were made as high as 13c. The market closes steady at 12½@12½¢. for Lake; 12½@12½¢. for electrolytic in ingots, cakes and wirebars. The average of the week for casting copper has been 12½@12½¢ cents.

Copper sheets, cold-rolled, are quoted 17.3c. per lb., large lots; and hot-rolled, 16.5c. Copper wire, 14½¢. base, carload lots at mill.

A buying movement, due largely to covering of bear accounts, made itself felt in the London standard market, beginning with Thursday of last week. The advance was gradual until Monday morning when prices opened almost £1 higher than at the close on Friday. This marked the culmination of the movement, and since then there has been a reaction, the quotations at the close being cabled at £55 15s. for spot, £56 10s. for three months.

Refined and manufactured sorts we quote: English tough, £60 10s.; best se-

lected, £59 10s.@£60 10s.; strong sheets, £71 10s.@£73 10s.

The production of the Nevada Consolidated from January 1 to March 20 is reported at 3,752,000 lb. of copper. During the same period the Cumberland-Ely reports a total output of 3,278,000 lb. copper.

Copper exports from New York and Philadelphia for the week were 5631 long tons. Our special correspondent gives the exports from Baltimore for the week at 355 tons of copper.

Imports of foreign copper into Germany in January were 11,788 tons, of which 11,125 tons were from the United States. Exports were 552 tons, leaving the net imports 11,236 tons; which is 2924 tons less than in January of last year.

Tin—A waiting attitude seems to be taken by operators in the London market, which does not show any decided tendency one way or the other. Quotations throughout the entire week fluctuated within very narrow limits, and the close is cabled at £129 2s. 6d. for spot, £130 12s. 6d. for three months.

The domestic market is very similar to that of London, and business here is confined to retail lots. Quotations are made at 28.50 cents.

Arrivals of Bolivian tin in Europe in February included 2138 tons concentrates, equivalent to 1407 tons fine tin.

The tin output of the Federated Malay States for the two months ended Feb. 28 was 9275 long tons in 1908 and 6794 in 1909; decrease, 2491 tons.

Lead—There has been a very good demand for this metal, particularly from the sheet and pipe manufacturers, and business is reported in larger volume than for some time past. However, the demand is being readily met at current prices and the close is unchanged at 3.82½@3.85 St. Louis, 3.97½@4c. New York.

The London market, after declining early in the week, showed a better tone and at the close is higher at £13 8s. 9d. for Spanish lead, £13 10s. for English lead.

Advices from Europe indicate that the plans for the European convention to control the production and price of lead are progressing.

Spelter—Business is very light and there is no change in the market, quotations at the close being 4.60@4.62½ St. Louis, 4.75@4.77½ New York. The New York quotation was 4.75@4.77½ for March 18-24, inclusive.

The London market has moved within narrow limits, and after advancing to £21 10s. for good ordinaries, closes at £21 7s. 6d. for that grade, and £21 12s. 6d. for specials.

Base price of sheet zinc is now 6½¢. per lb., f.o.b. La Salle-Peru, Ill., less 8 per cent. discount.

World's Production of Copper

The first estimate of the world's production of copper in 1908 comes from Aron Hirsch & Sohn, of Halberstadt, Germany. Substituting our own figures for North America, it appears the total production was approximately as follows:

Country.	1907.	1908.
Germany.....	24,300	23,300
Austria-Hungary.....	1,000	1,350
Italy.....	3,000	3,150
Russia.....	15,000	16,520
Sweden and Norway.....	11,964	12,015
Spain and Portugal.....	51,200	51,700
Turkey.....	2,600	2,400
Chile.....	25,000	36,580
Peru.....	9,500	17,000
Bolivia.....	2,400	2,500
Cape Colony.....	7,000	7,000
Australia.....	46,000	43,000
Newfoundland.....	2,000	2,000
Japan.....	37,500	40,000
Others.....	3,300	5,000
Total.....	244,764	263,515
United States.....	392,519	425,177
Mexico.....	56,567	37,571
Canada.....	20,695	23,881
Grand total.....	714,545	750,144

Apart from the conditions in the United States, Canada and Mexico, as to which we have previously commented, the most noteworthy features of the above statistics are the large increases in the outputs of Chile, Peru and Japan.

British Metal Imports and Exports

Imports and exports of metals in Great Britain, two months ended Feb. 28, figures in long tons, except quicksilver, which is in pounds:

	Imports.	Exports.	Excess.
Copper.....	21,895	10,510	Imp. 11,385
Copper, 1908.....	22,538	13,265	Imp. 9,273
Tin.....	7,150	6,658	Imp. 492
Tin, 1908.....	6,566	6,402	Imp. 264
Lead.....	37,823	6,338	Imp. 31,485
Lead, 1908.....	38,353	5,989	Imp. 28,764
Spelter.....	16,915	1,153	Imp. 15,762
Spelter, 1908.....	16,807	1,096	Imp. 14,801
Quicksilver, lb.....	409,157	171,756	Imp. 237,371
Quicksilver, '08.....	821,650	476,021	Imp. 345,629

Ores:

Tin ore and con.....	2,587		Imp. 2,587
Tin ore, 1908.....	4,559		Imp. 4,559
Pyrites.....	136,790		Imp. 136,790
Pyrites, 1908.....	168,036		Imp. 168,036

Copper totals include metallic contents of ores and matte. Exports include re-exports of foreign material. Of the imports in 1909 the United States furnished 83 tons copper matte, 2980 tons fine copper and 5038 tons lead.

Other Metals

Antimony—No business is reported. In the absence of sales, prices are nominally unchanged at 80/87½c. for Cookson's; 7½c. for Hallett's; 73½c. for ordinary brands.

Aluminum—The Aluminum Company of America quotes 2½c. base for No. 1 ingots; 33/34c. base for sheets. Nothing new reported as to foreign metal.

Quicksilver—Business has been quiet. New York quotations are unchanged at \$45@46 per flask of 75 lb. San Francisco prices are \$44@45 for domestic sales, \$42

@43 for export. London quotation £8 7s. 6d. per flask, with 1s. 3d. less named by second hands.

Nickel—Large lots, contract business, 40@45c. per lb. Retail, spot, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. The price for electrolytic is 5c. higher.

Cadmium—Current quotation 75c. per lb. in 100-lb. lots, at Cleveland, Ohio.

Magnesium—Quotations for this metal are \$1.25 per lb., New York, in 100-lb. lots; for 5-lb. lots, \$1.40 per pound.

Zinc and Lead Ore Markets

Joplin, Mo., March 20—The highest price reported paid was \$40.50 per ton for concentrate carrying 63 per cent. zinc sulphide on car sample assay, sold on a basis of \$37.50. As high as \$38 base was paid and nothing was reported sold in quantity under a \$36 base. The most material advance of prices was in medium and lower-grade sulphides. Zinc silicate sold on \$18 and \$19 per ton of 40 per cent. zinc, selling as high as \$24. The average price, all grades, was \$32.50 per ton.

Lead ore was generally advanced ½¢ per ton, while some large sales were

made at the week end, but not delivered, at a \$2 gain, bringing \$52.50 f.o.b. cars. Medium grades ranged between \$50.50 and \$51.50; all grades averaged \$50.80 per ton.

The smelters now own the bulk of the stock in the bins at the mines, and will need to buy but lightly for a few weeks, which will have a tendency to offset the momentary excitement attending the report on the tariff.

Platteville, Wis., March 20—The base price paid for 60 per cent. zinc ore was \$38 per ton. No premium price is reported. For 80 per cent. lead ore \$46 per ton was paid.

SHIPMENTS, WEEK ENDED MAR. 20

Camps.	Zinc ore, lb.	Lead ore, lb.	Sulphur ore, lb.

Cuba City.....	71,150		
Total.....	1,402,490	66,700	209,200
Year to Mar. 20.....	21,767,729	777,880	2,189,850

In addition to the above there was shipped to the American Zinc Ore Separating Company, 129,670 lb. and to the Joplin Separator Works, 482,600 lb. zinc ore. The shipment of zinc ore is still curtailed about 25 per cent. on account of the bad condition of the wagon roads; a number of outlying mines, with bins filled, are unable to get any of their stock to market.

Chemicals

New York, March 24—The market is extremely dull, but prices hold to last week's figures.

Copper Sulphate—Prices remain at \$4.60 per 100 lb. for carload lots and \$4.85 for smaller lots. No large sales reported.

Arsenic—Quotations on white arsenic are 3c. per lb. No trading of any moment is noted.

Nitrate of Soda—Prices remain at 2.15 @2.17c. per lb., with few sales made.

Mining Stocks

New York, March 24—Early in the week the general stock markets generally remained quiet and uncertain, but on Monday a strong upward movement developed, chiefly based on good buying in London of American securities. This strength continued and the market has been active, although today has showed a slight reaction. The anthracite-coal stocks weakened a little on strike rumors. The general tone of the market is strong.

On the Curb the leading incident in the first part of the week was a break in Ohio Copper under the influence of heavy selling. This lasted only for a couple of days, and the stock lapsed into quietness again. Toward the close the other copper

NOTE.—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

stocks showed considerable strength and were fairly active. The Cobalt stocks were generally in demand and brought good prices. The Nevada gold stocks are waking up a little, more attention being paid to them, but prices are not strong.

Boston, March 23—A dull and uninteresting market is all that can be said of the present conditions. Weak at times and then a degree of strength in certain stocks. The weakness in part is said to have been due to the liquidation of some 12,000 shares of mining stocks for Western account. Notwithstanding this, declines were of little consequence, and prices tonight are generally above those of a week ago. There was some selling of Atlantic, Lake and North Lake for exchange into East Butte.

The Tamarack company is said to have a floating indebtedness of \$700,000, which was the reason that Calumet & Hecla people did not take the property over with the other Bigelow mines. The Isle Royale annual report shows a deficit of \$451,211 for the year 1908. This included \$309,460 spent for construction, etc.

On the Curb First National fell to \$6. Ohio Copper had a bad break to \$6, but is back to above \$7. Ojibway has been taken from the Curb and placed on the unlisted department of the Stock Exchange. An issue of \$250,000 bonds is announced by the Black Mountain Mining Company to retire a floating indebtedness and provide working capital.

NO. 14.

Milling and Cyaniding Practice at El Oro, Mex.

Interesting Features Are the Tailings Wheels, the Burt Filters, the Immense Cone Settler and the Continuous Agitation in Series of Tanks

BY CLAUDE T. RICE

El Oro was the pioneer district in Mexico to undertake the cyaniding of a gold ore containing much silver. Consequently it was here that much of the knowledge regarding silver cyanidation was obtained. Later Guanajuato undertook the treatment, by that process, of an ore containing

all this work owes much of its success to the early work done at El Oro.

Not only was El Oro a pioneer in cyaniding gold-silver ores, but it was the first camp in North America to adopt the tube mill for grinding on a large scale. At first the ore was crushed in water,

chuca tank is to be used for agitating the slime. The name of El Oro is also well known because of types of machinery perfected there. The early El Oro type of liner for tube mills has now been modified into a newer type at the Dos Estrellas mill.

EL CEDRO MILL, COMPANIA MINERA LAS DOS ESTRELLAS

EL ORO MILL

MEXICO MILL

considerably more silver than the El Oro ore, and finally Pachuca, emboldened by the example of Guanajuato, began to treat by cyanidation a silver ore in which the gold content is very small. Since then in other districts, the cyanidation of silver ores has been carried on successfully, but

but finally crushing in solution was adopted. In the early days (and in July, 1908, at two mills) the slime was agitated by air hose; later mechanical agitation was adopted, and now in the tailings mill of the Esperanza Mining Company which is rapidly approaching completion, the Pa-

Edwin Burt, cyanide superintendent for El Oro company, has invented a pressure filter which is used throughout the camp, but not content with that he is at work on a more improved type. While the Burt filter is at present the only filter used in the district the Esperanza com-

pany in its new mill is installing Merrill presses; these will be used in a new way, washing the slime cakes from the center outward. Walter Neal, superintendent of the Dos Estrellas company's cyanide plants, has erected an immense dewatering cone which is probably the largest in the world, being 35 ft. high by 34 ft. in diameter; this is used to thicken the slime pulp going to the tanks for agitation. There are many other interesting features; the Burt classifier, a modification of the Burt filter, which is used for filtering solutions before they go to the precipitation boxes; and the continuous agitation, in a series of deep, flat-bottomed tanks, which is used

the newest mill in the district, is equipped with such a wheel. But other features of African practice are being abandoned. The El Oro and Mexican companies have adopted complete sliming and the Dos Estrellas completely slimed its ore for several months but has again returned to slime-and-sand treatment. So it will be seen that El Oro is of special interest from a metallurgical view-point.

At El Oro, most of the ore milled is oxidized but some is sulphide. In the sulphide the gold occurs in the pyrite mainly, while the main silver mineral is argentite. The gangue is highly silicious. The ore mined by the Dos Estrellas com-

work, El Oro company for the last year has been completely sliming its ore. In the two mills of this company there are 200 stamps, 100 weighing 1000 lb. each and 100 weighing 1140 lb. each. The ore after being broken in gyratory crushers goes to the stamps which make 102 drops, 7 in. high, per minute. The ore is crushed in solution, titrating 0.01 per cent. KCN, through 30-mesh screens; about 30 to 40 per cent. of the battery pulp will pass a 200-mesh screen.

The pulp from the two mills unites and passes through a series of classifying cones. All of these cones are fitted for using ascending currents in them, and in

BURT FILTER PLANT, EL ORO MILL

SLIME TANKS, EL ORO MILL

PRECIPITATION ROOM, MEXICO MILL

PRECIPITATION ROOM, EL ORO MILL

in giving the final wash to the slime at El Cedro mill. Finally Mr. Neal has perfected a tube-mill discharge which permits the feeding of grinders to the mill while it is running. This gives good satisfaction and is used quite generally in the district.

The South African origin of El Oro cyanide practice is well shown by the use of tailings wheels instead of centrifugal pumps or bucket elevators for elevating the sand for regrounding. These wheels at El Oro are of moderate height, but they have succeeded so well that, while South Africa is discussing the abandonment of the tailings wheel, one has recently been built at El Cedro mill, and the Mexico,

pany averages 13 grams gold and 224 grams silver from the Dos Estrellas workings and 10 grams gold and 100 grams silver per ton from the Cedro workings. The ore mined by the Esperanza company averages 13 grams gold and 80 grams silver per ton from the San Rafael vein (oxidized ore) and from the sulphide vein 30 grams gold and 300 grams silver per ton. The Mexico ore averages about 17.5 grams gold and 205 grams silver per ton, while El Oro company's ore averages about 12 grams gold and 93 grams silver per ton.

EL ORO COMPANY'S MILLS

After many changes, due to its pioneer

some an ascending current is used. The overflowing slime goes to the agitating tanks while the underflow is elevated by a sand wheel, 40 ft. 6 in. diameter, to the tube-mill feed cones. The sand goes to 7 tube mills—two Abbe and five Krupp mills. These mills are of several different sizes, but the most efficient is 4 ft. diameter by 10½ ft. long, as the shorter sizes with relatively larger diameters do not give so good results. These tube mills, owing to the high starting torque, are run by 75-h.p. Westinghouse motors and are kept a little more than half-filled with sand and grinders. The tube mills are fitted with the original Brown design of El Oro liner and with a Neal discharge,

the reverse worm being used without the baffle. This form of discharge works well and has given good satisfaction; it is described and illustrated in another part of this article.

At El Oro the tube-mill equipment is not large enough for complete sliming so that only about 80 to 85 per cent. of the tube-mill discharge passes a 200-mesh

of the pump, but to insure complete aëration, a small jet of air is admitted to the tank. The slime pulp enters the vats through a central perforated box extending about 15 in. below the surface of the charge and inclosed in an outer box whose sides flare upward; this construction concentrates the stream of slime entering the tank. The slime is agitated in solution

The third and fourth agitations are with barren solution; the first two with unprecipitated solution. The barren-solution washes from one agitation become the first and second washes for the next charge.

The washed slime is run to deep settling tanks, 34 ft. diameter by 20 ft. deep. About 80 per cent. of the settled slime is treated

DOS ESTRELLAS MILL

EL CEDRO MILL

SAND PLANT, EL CEDRO MILL

SLIME PLANT, EL CEDRO MILL

METHOD OF CHARGING TUBE MILLS, EL CEDRO MILL

TUBE-MILL FLOOR, EL CEDRO MILL

screen. The slime going to the tube mills is thickened to about 50 per cent. moisture before it enters the mills. Ore is used for grinders. There are 15 agitation tanks, 34 ft. diameter by 12 ft. deep, and 6 agitation tanks, 34x20 ft. deep, being old converted settling tanks. The agitation is effected by revolving paddles and a centrifugal pump. Aëration is effected by means

titrating about 0.04 per cent. KCN at a dilution of 3 solution to 1 pulp. The strength of the solution is varied somewhat according to the amount of silver in the ore. About 250 grams of lead acetate are added to the tanks per ton of slime.

The total slime treatment lasts 52 hours. The first agitation last six hours; the second, third and fourth, one hour each.

on Burt filters, while the remainder, owing to the insufficiency of the filter equipment, is discharged after settlement in only the deep tanks. There are five Burt presses¹ 42 in. diameter by 20 ft. long. These are considerably smaller than those used by the Dos Estrellas company. No washing

¹Described in this JOURNAL, Sept. 5, 1908.

is done in the press. The filtering pressure, 40 lb. per sq.in., is obtained by gravity. It takes 35 min. to filter a charge. The cakes as discharged contain about 30 per cent. moisture.

The pregnant solutions are precipitated in ordinary precipitation boxes. The short zinc is separated by screening and is used over again so that there is no acid treatment of the zinc. The precipitate is briquetted with fluxes.

The extraction of the gold is about 93 per cent. and of the silver about 70 per cent., making the total extraction about 89 per cent. The zinc consumption is 0.9 lb. per ton and that of cyanide 0.8 lb. per ton of ore crushed. The cost of milling the ore is \$0.40 per ton of ore crushed and of cyaniding is about \$0.90 per ton.

per minute. The ore is crushed in cyanide solution, titrating 0.02 per cent. KCN, and through 8-mesh screens. The stamp duty is about 7 tons per 24 hours. The pulp from the batteries contains about 10 to 15 per cent. that will pass a 200-mesh screen.

This pulp goes directly to the classifiers above the tube mills. There are six Krupp mills, 4 ft. diameter by 19½ ft. long, but only four of the tube mills are needed at present. The motors are connected by gearing to the tube mills. These mills are run at 31 r.p.m.; at the upper end the journal turns in trunnion bearing and at the lower end on two rollers.

The discharge from the tube mills goes to classifying cones. The overflow, 90 per cent. of which will pass a 200-mesh

per cent. KCN. Then four agitations, lasting one hour each are given in residual solution titrating 0.03 per cent. KCN. The slimes are filtered in three Burt filters which run only about half the time. The filtered solution is passed through a Burt clarifier which is quite similar in construction to a Burt filter but is placed horizontal instead of at an angle of 45 deg. as is the filter. The clarified solution then goes to storage tanks above the precipitation house. There are nine zinc-boxes each having five compartments, 48 in. wide by 30 in. long by 20 in. deep. The zinc-room practice is quite similar to that at El Oro mill.

The cyanide consumption is a little more than 1 lb. per ton of ore crushed. The zinc consumption is about the same as at

BURT FILTERS, EL CEDRO MILL

BURT FILTER, SHOWING DISCHARGE

BURT CLARIFIER, MEXICO MILL

The ore contains about \$7.90 in gold and \$1.50 in silver per ton.

THE MEXICO MILL

The Mexico mill is the newest mill in the district and the simplest. It treats about 280 tons of ore per day. The ore from the mine contains \$11.70 gold and 6.6 oz. silver per ton; as the silver content is greater than in most of the ore mined at El Oro, the treatment at the Mexico mine is correspondingly lengthened.

The ore is crushed in a jaw crusher and one set of rolls for the oversize, until all of it passes a 2-in. grizzly. This is done in a separate breaker house. The ore then goes to the mill building.

There are 40 stamps weighing 1180 lb. each and making 102 drops, 7 in. high,

screen, goes to the agitation vats while the underflow goes to a riff-raff wheel, 40½ ft. in diameter, which returns the oversize to the tube mills. This wheel requires only about 6 h.p. to run it, and the repairs are almost nothing.

There are 12 agitation tanks, 34 ft. diameter by 12 ft. deep, but one or two of the tanks are used to receive the pulp going to the Burt filters. These tanks are similar in every respect to those used at El Oro mills. The main agitation is mechanical, but centrifugal pumps are added for transferring and aiding in agitation while a small air jet increases the aëration. The slime is agitated in cyanide solution at a dilution of 1 slime to 3 water. The total slime treatment takes four days. The first agitation lasts 24 hours and is with solution titrating 0.05

El Oro mill. The cost of milling is \$0.30, of cyaniding, \$1.28 and of water supply \$0.02, making the total treatment cost \$1.60 per ton of ore crushed. The extraction on the gold is from 94 to 95 per cent. and on the silver from 83 to 84 per cent., making a total theoretical extraction of from 91.5 to 92 per cent.

THE DOS ESTRELLAS MILL

The Dos Estrellas mill belonging to the Compañía Minera Las Dos Estrellas is interesting, for it shows fairly clearly the gradual development in the mechanical side of the cyanide process. Starting as a pan-amalgamation mill, the plant was changed, after the cyanide process had been proved applicable to the gold-silver ores of the camp, so as to use that process. Therefore the mill lacks unity, and of

course is not comparable to the newer Cedro mill belonging to the same company.

At first this mill like the others used water in the batteries, but about a year and a half ago the scheme of treatment was changed, and the ore was crushed in weak cyanide solution. Rectangular tanks for treating the slime were first used, for that was the practice when they were erected; later cylindrical tanks and mechanical agitators were installed, and now the company is equipping the old square tanks with mechanical agitators, such as are used in the cylindrical tanks, so as to do away with air-agitation by means of movable hose. Provision is being made for separately treating the sulphide ore, and gradually the sliming capacity of the plant is being increased so that probably finally all the ore will be slimed; in fact for a few months since my visit all the ore was slimed.

The Dos Estrellas mill is at present treating 460 tons of ore per day averaging 13 grams gold and 224 grams silver per metric ton. This ore is first crushed in 15x9-in. Blake crushers, and then goes to the battery bin. Thence it is fed by Challenge feeders to the 130 stamp, 90 of which weigh 1250 lb. and the other 40 only 950 lb. Thirty of the stamps are crushing sulphide ore, while the rest are running on oxidized ore. At present the

containing about 60 per cent. moisture, to the tube mills. There are four Allis-Chalmers tube mills, 5x24 ft. long, having a modified El Oro lining and a Neal discharge-piece.

The Dos Estrellas type of El Oro lining is similar to the original El Oro lining.

DOS ESTRELLAS TYPE OF EL ORO TUBE-MILL LINER

baffle, made necessarily in two parts so that it can enter the mill. These two pieces bolt into the discharge of the tube mill. With this discharge piece no screen is used, for this device acts as a baffle, since the slant of both interior and exterior surface of the end projecting into the tube mill is such that any ore or pebbles striking either surface bounce back into the mill. In a tube mill having a larger discharge than the Allis-Chalmers mill a reverse-screw arrangement is added. The advantage of these discharge pieces is that it enables the mill to be charged with pebbles while it is running. At the Dos Estrellas and Cedro mills by using the Neal discharge piece the time that the tube mills are grinding is 97 per cent. of the total time, that is provided none has to be shut down to be relined.

With quartz for grinders the modified El Oro lining lasts about eight months, but with pebbles their life is increased to 12 months. The charge of grinders fills the mill a little more than half full. About two tons of quartz grinders are used per day per tube mill. Two of the tube mills run at 28 and two at 26 r.p.m.; about 60 h.p. is required to run a tube mill half-filled with quartz grinders. About six metric tons of dry ore are crushed per hour per tube mill; the heads contain 13 per cent. above 40-mesh; 41, between 40 and 80; 11, between 80 and 100; 12, be-

SLIME TANK, SHOWING WINGS FOR PROMOTING AGITATION

SETTLING BOX FOR USE IN CLEAN-UPS

two classes of ore are cyanided together, but changes are being made so that the sulphide ore will be treated separately from the oxidized ore as it requires a longer and somewhat different treatment than the oxidized ore. The solution used in the batteries is unprecipitated solution titrating 0.1 per cent. KCN. It is the last washes from the slime and the sand tanks. The stamps crush through a 30-mesh, No. 34-wire screen, and make 106 drops, 6 in. high, per minute. The oxidized ore goes direct from the stamps to the tube-mill classifying cones, but the sulphide ore is first concentrated, the slime on Johnston and the sand on Wilfley tables, before it joins the oxidized ore. These cones remove the slime and feed a thickened pulp.

but the back of the liner is made lighter, and to strengthen this liner, where it is weakened by the holes for the bolts that hold it in place, cross webs connect the two ribs together. The liner fills with pebbles like the older type, but in the accompanying illustration the mill had just been relined and had not yet been run. This design allows a much lighter liner to be used than the original form of design permits. This is some advantage when it is desired to use the El Oro type of lining in a mill whose bearings have not been designed for such an increase in weight.

The Neal discharge piece, designed and patented by Walter Neal, the superintendent of the Dos Estrellas and El Cedro plants, consists of an annular, tapering

tween 100 and 150; 2, between 150 and 200; and 21 per cent. through 200-mesh. The discharge contains 1 per cent. on 40 mesh; 22, between 40 and 80; 11, between 80 and 100; 22, between 100 and 150; 8, between 150 and 200; and 36 per cent. through 200 mesh.

The discharge from the tube mill at present is elevated by centrifugal pumps to a second system of two large classifying cones working in series, but a bucket elevator is being installed to replace the pumps. The underflow from the first cone returns to the tube mills, and the overflow goes to the second cone; the underflow from the second cone goes to the sand-receiving tanks and the overflow to the slime-collecting tanks.

These classifying cones, although designed to be run as hydraulic classifiers, are now used as simple cone classifiers, for with Mexican labor it is difficult to keep the water-jet pipe from plugging up. The sand going to the receiving tanks contains 1 per cent. sand on 40 mesh; 14, between 40 and 80; 14, between 80 and 100; 48, between 100 and 150; 4, between 150 and 200 and 19 per cent. through 200 mesh.

There are 12 sand-receiving tanks, 21 ft. diameter and $5\frac{1}{2}$ ft. deep. The slime overflowing from these tanks is returned to the large cones that reclassify the tube-mill discharge. The sand is given a double treatment; the first in the receiving tanks, the second in the treatment tanks proper.

At the tube mills 200 grams of lead acetate per ton of total ore milled is added to the pulp, but the lime for neutralizing the acid is added to the slime in the slime-settling tanks.

In the receivers the sand is washed

mechanical agitators. For the final wash the slime is discharged to the wooden slime washers where it receives one agitation by transfer; then it is allowed to settle for as long a period as the capacity of the settlers will permit. The thinner pulp on the top is treated in the Burt presses, while owing to the fact that the capacity of the slime filters is not large enough to handle all the slime, the thicker pulp near the bottom of the tank is discharged directly to the creek.

There are two Burt filters 25 ft. long by $4\frac{1}{2}$ ft. diameter, having 35 leaves each. The rated capacity of each of these filter-presses is 200 tons of dry slime per day, but, as the slime has to be charged into the filter by two 6-in. centrifugal pumps working in series, considerable trouble is caused by the pumping system owing to the rapid wearing out of the impellers and pump casing. Besides, the filters are handicapped by the fact that the capacity of the plant does not allow of sufficient settle-

The extraction on the sand is 88 per cent. of the gold and 73 per cent. of the silver. The extraction on the slime is approximately the same because the slime plant at present is purposely crowded until the extraction on the slime is the same as that on the sand. Of course normally the extraction on the slime is much better than on the sand. The cyanide consumption at the Dos Estrellas mill is 1 kg. per metric ton of ore crushed; the zinc consumption, 600 kg.; and the lime consumption, 12 kg. per ton. The average cost of crushing and cyaniding from January to June, 1908, was 2 pesos per ton.

As the zinc-room practice at the Dos Estrellas mill is almost identically the same as that at the Cedro mill, the details will be described later.

THE CEDRO MILL

The Cedro mill, built two and a half years ago, was designed by H. Bossuat, general manager, H. Jouanen, assistant general manager, and C. E. Rhodes, at that time superintendent of the cyanide department of the Dos Estrellas company. It is one of the best in the Republic, and, as the company expends considerable money on experimenting and tries hard to keep the mill well abreast of milling progress, this mill is indeed interesting. The practice of this mill is changing continually, and what I write about the method of milling used at present will probably be no longer true three months from now. In fact since July for several months at both the Cedro and the Dos Estrellas mills the ore was completely slimed, but as there was little difference in results, the ore is again being treated as sand and slime. In the meantime further experimenting in regard to complete sliming of the ore is being carried on.

When I was there in July they were just beginning to operate the Burt filter and were just finishing the construction of probably the largest settling cone in the world; since then the cone has been put in operation. This cone is 34x34 ft. with a vertical rim 1 ft. high, making the total vertical height 35 ft. It is used to thicken the slime pulp before charging it into the agitation tanks. The slime at El Oro is extremely quick settling, and so by using this cone the two tanks formerly used as collecting tanks are made available for agitation. Although the discharge pulp is not as thick as had been hoped, still the pulp is sufficiently dewatered so that it can be agitated in the tanks as they are being filled, and so the cone fulfils the purpose for which it was designed. The total mill product after being ground to slime in the tube mills goes to the cone at a dilution of 8 solution to 1 slime and is thickened to a dilution of 4 to 1 when the pulp is fed so as to pass through the cone in 3 hours and 55 minutes. At present about 460 tons of slime a day are passing

NEAL DISCHARGE FOR TUBE MILLS

for five days, with cyanide solution titrating 0.15 per cent. KCN, 90 tons of solution being used. Then it is shoveled into cars and charged into the leaching tanks, 17 in number, 32 ft. diameter by $4\frac{1}{2}$ ft. deep where it is given a 10-day treatment. It is leached first with 80 tons of solution titrating 0.4 per cent. KCN and then with 350 tons of 0.1 per cent. solution. The sand is discharged by shovel into cars and hauled by a Lidgerwood hoist up the slightly inclined tailing pile and dumped.

SLIME TREATMENT

The slime from the separating and thickening cones above the tube mills flows to the slime-collecting tanks which are rectangular cement tanks; at the time of my visit the pulp in these was agitated by means of air hose, but mechanical agitators were being installed. From these the slime is discharged by gravity to the circular, steel, agitation tanks fitted with

ment to feed the presses with thick slime, consequently the capacity of the presses at this mill is much lower than the rated capacity. A pressure of 40 lb. per sq. in. is used in charging the Burt filter. At the Dos Estrellas mill the cycle is 35 min.; 25 min. being the actual time of filtering, since 10 min. is consumed in handling and discharging the pulp. In these large filters a charge of 6 tons of dry slime is filtered in one operation of both presses. The entering pulp contains 70 per cent. moisture, while the discharged cakes contain 30 per cent. moisture. The cake is not given a water wash, as that makes the cycle too long.

The total time of slime treatment is four days; agitation, not including time of transferring, amounts to 17 hours. The pulp is agitated at 4 solution to 1 slime, the solution titrating 0.1 per cent. KCN. The total dilution (tons solution decanted per ton of slime) is about 6 solution to 1 slime.

through the cone. The overflow from the cone is perfectly clear and goes directly to the sand filters; thence to the precipitation boxes.

The excellent agitation and aëration obtained during the crushing, classification and re-grinding of the ore results in an extraction of 74.1 per cent. of the gold and 56.2 per cent. of the silver on the settled but unwashed samples of the underflow from the cone. This fact suggests unexpected possibilities in shortening and simplifying the treatment. But in considering this it must also be remembered that, as at the present time the mill is treating a greater proportion of ores from the upper levels, the gold and silver are more readily dissolved than if more of the less oxidized ore coming from the lower levels were being treated.

There are many other interesting features at this mill; for instance, the continuous flowing of the pulp through a series of agitation tanks in the final part of the agitation treatment; the adoption of the tailings wheel for returning to the cones above the tube mills the pulp that has passed through the tube mills; the manner of using up the short zinc; the carbon filters in the last compartment of the zinc boxes; the method of screening the precipitate, as well as several other points in the treatment. In July the mill was sliming less than half the ore, but since then, after sliming all the ore for several months, the mill has been sliming about two-thirds of the ore.

The sand plant is equipped with a complete Blaisdell system for handling the sand in the tanks and a Robins belt conveyor for taking the tailings to the dump. While, owing to the ignorance of the Mexican labor, the cost of repairs on such a system is much higher than in the United States, the fact that on a feast day two foreigners can operate the system more than offsets this disadvantage of high cost for repairs.

The Cedro mill is built on a side hill, but unfortunately the difference in elevation is not sufficient to permit of charging the Burt filters entirely by gravity, and so a semi-gravity system must be used. The mill at present is crushing 600 metric tons per day. This ore, which assays 10 grams gold and 106 grams silver per metric ton, is mainly oxidized ore and contains little sulphide so that none of it is treated on concentrators.

The ore, brought from the mine by electric haulage, is crushed in six 15x9-in. Blake crushers to about 1½-in. size, and then goes to the battery bin which holds 9000 tons. Suspended Challenge feeders feed the ore to the 120 stamps, which weigh 1250 lb. and make 102 drops, 6 in. high, per minute. On the batteries 8-mesh. No. 18-steel-wire screens are used. The ore was formerly crushed in unprecipitated cyanide solution titrating 0.1 per cent. KCN, but now most of this is precipitated

before being returned to the batteries. About 8 tons of solution are used per ton of ore.

The pulp from the stamps goes directly to the cones above the tube mills; there are five of these tube mills, each 24x5 ft.

THE LARGE SETTLING CONE BEFORE COMPLETION

THE COMPLETED SETTLING CONE, EL CEDRO MILL.

diameter, made by the Allis-Chalmers Company. All are fitted with Neal discharge-pieces so that the grinders (coarse ore from the vein) are fed to the mill without stopping it. The ordinary system

of three small cones is used to separate the slime and thicken the pulp going to most of the tube mills, but one mill is fed by one large cone, 7½ ft. high by 5 ft. diameter, as is the practice in South Africa. With this one cone no trouble is experienced in getting an underflow that really carries only 50 per cent. moisture—a difficult thing to do when using a series of smaller cones to feed the tube mill. Besides, there is only one cone to watch for each tube mill. The tube mills run at 26 r.p.m., and as at the Dos Estrellas mill they are lined with the modified El Oro liner. The pulp from the tube mills goes to the main system of classifying cones where the sand and the slime are separated. The sand goes to the sand plant, and the slime, after joining the slime from the cones feeding the tube mills, goes to the slime plant. In July about 45 per cent. of the pulp was treated as slime and 55 per cent. as sand.

The sand is collected in one of the 10 sand-receiving tanks, 7x22 ft. diameter. The overflowing slime and fine sand from the receivers is returned to the cones by a Byron Jackson 4-in. centrifugal pump. The sand drains 30 hours in the receiving tanks, and then is transferred to the leaching tanks by means of a Blaisdell system. There are 12 leaching tanks 36x5½ ft. deep (leaching depth 5 ft.), each holding 130 tons. In the leaching tanks the sand is given a treatment lasting 6½ days. First 48 tons of strong solution titrating 0.4 per cent. KCN and then 96 tons of weak solution titrating 0.1 per cent. KCN are used. The sand tailings contain 16 per cent. moisture when discharged and assay 1 gram gold and 48 grams silver per ton. The extraction on the gold is 90 per cent., but on the silver only 55 per cent., due to the fact that a certain amount of the silver is apparently unextractable by the cyanide. Therefore, on that account as the ore treated at the Cedro mill does not contain as much silver as that treated at the Dos Estrellas mill and as the insoluble portion is about the same in both ores, the extraction of silver at the Cedro mill is much lower.

SLIME TREATMENT

The cyanide plant at the Cedro mill is admirably laid out, for it is so arranged that all the slime tanks and also all the sand tanks can be seen from the shift-boss' office which rises like a conning-tower among the cyaniding tanks. This is especially advantageous as it permits the man in charge to see everything that goes on and makes the overflowing of any tanks inexcusable. This overflowing is apt to occur where too much dependence is placed upon the Mexican employees.

The slime treatment at the Cedro is novel. At first the slime after being collected in two of the tanks is treated by agitation and decantation in the usual way with mechanical agitators. Then it is dis-

charged to the deep tanks, where it is given a continuous agitation as it flows from one of them to the other. There are 12 of the ordinary agitation tanks 36x10 ft. deep, and six of the continuous agitators, 36x20 ft. deep. These are connected so that the pulp flows from the bottom of one into the bottom of the next and out from the top of that tank into the top of the next tank. In these tanks two sets of agitator arms are used, one set about 20 in. above the bottom and the other set about 10 ft. above the bottom. In the tanks, 10 ft. deep, only one set of agitator arms is used.

In the tank where the agitation and decantation treatment is given, 100 grams of acetate is added per ton of total ore crushed. The slime is agitated in solution titrating 0.1 per cent. KCN, and the dilution is about 4 to 1. The total time of contact in this first agitation period is 70 hours; 16 hours of this time the slime is in agitation, and 5 to 6 agitations are given. The solutions from these agitations, as well as the overflow from the slime-collecting tanks, are precipitated. The last wash decanted from the settling tanks, and the solution from the Burt slime presses together with enough of the last washes from the 10-ft. tanks to make up the necessary amount is returned to the battery-solution storage tanks without precipitation.

In the deep tanks the slime is given a continuous agitation lasting 186 hours. From the last tank of the series the slime is discharged, part to the filter presses and part to settling tanks, 36x20 ft. deep, the same size as the continuous-agitation tanks, where it is settled and from which, finally, after the supernatant solution is decanted, it is discharged to the creek. The slime from the settlers contains about 40 per cent. moisture when discharged. The continuous-agitation tanks are transformed settlers that were made available by the use of Burt slime filters. This method of continuous agitation through a series of tanks is said to possess advantages over the method of agitating and decanting in the same tank and is being further developed.

There are two Burt filters, 25x4½ ft. diameter. Owing to the insufficiency of the head, these work on a semi-gravity system, and a 6-in. Butters centrifugal pump is required to obtain the 50-lb. pressure used in filtering. The filtered solution and that decanted from the settling tanks is returned to the stamps without precipitation. The extraction from the slimes is 92 per cent. of the gold and 65 per cent. of the silver.

THE PRECIPITATION ROOMS

The solution going to the precipitation room is passed through sand filters before it enters the precipitation boxes which have six compartments, 36x36x30 in. deep. About 3,000 tons of solution are

precipitated each day. There are three regular precipitation boxes and one short-zinc precipitation box treating strong solution, and 23 precipitation boxes treating weak solution. The end compartment of each box is filled with charcoal that acts as a filter and increases the saving somewhat. At clean-up time the charcoal filter is washed off with a hose. After being in use for several months the charcoal is burned, and the ashes added to the precipitates for melting.

The short zinc is used in a special box in which each compartment is fitted with a set of five trays, each 5 in. high, one tray resting on the other below. On these an 8-mesh screen is used. The short zinc is laid out on these screens in a layer 1 in. thick. This method keeps the short zinc from matting and gives the cyanide solution a chance to get at all the zinc. About three-fourths of the short zinc can be consumed this way; when too much short zinc accumulates some of it is melted down with the next clean-up. The short-zinc box is used only for precipitating strong solution, and the solution after passing through the short-zinc box goes to one of the regular strong-solution boxes to insure complete precipitation.

In cleaning up, the precipitate is washed into a settling box, shown in an accompanying illustration; this is mounted on wheels, and has a small feed compartment down which the precipitate and solution passes. In this box most of the precipitate and short zinc settles so that the overflowing solution is quite clear and not until near the end of the clean-up does the 60-mesh screen, used to separate the short zinc, become clogged. Consequently the short zinc gives less trouble during clean-ups and, as the heavier precipitate is held back until the last, the speed of filtering in the press is increased. This settler makes a clean-up much easier.

In fluxing the precipitate, which contains 60 per cent. metals, slag from the assay office, amounting to 30 per cent. of the weight of dry precipitate melted, is used as part of the flux. Some lead from this slag is reduced and goes into the bullion, but that does no harm. The assay slag forms an excellent flux; unfortunately all the flux required cannot be furnished by the assay office. The first bars obtained are remelted. In pouring the pots, the top slag is poured into a cone having a clay-plugged tap hole; when near the metal, the pot is poured into the ingot molds. When a shell an inch thick has formed in the first cone, the tap hole is opened, and the interior slag run off. This slag is shipped to the smelter, but the slag shell and the slag from the ingot molds are remelted.

Cyanide consumption amounts to 0.56 kg. per ton of total ore crushed; zinc consumption amounts to 0.66 kg., and lime consumption 7.6 kg. The cost of cyaniding is 1.50 pesos.

The Mount Morgan Gold Mining Company

The report of this famous Queensland company for the half-year ending Nov. 30, 1908, states that the total revenue from all sources amounted to £507,238. The profits for the half-year, including a balance of £3421 carried forward from last account, was £135,250. The average gross price per ton obtained for copper realized was £59 3s. compared with £65 18s. for the previous half-year, irrespective of the gold values in each case. During the half-year 222,793 tons of ore were mined and treated at the works, yielding 3272 tons of blister copper and 84,037 oz. of fine gold; in addition to which 230 tons of copper precipitate were recovered. The Electrolytic Copper Refining Company, in which the Mount Morgan Company is interested, has completed the construction of its plant at Port Kembla, and will now be prepared to treat blister copper.

During the half-year two serious falls of ground occurred in the mine, causing the death of 12 men. This is the first time, since the company was formed 20 years ago that a serious accident has taken place. The first accident was due to a difficulty in supporting the roof previous to the placing in position of cribbing to form the ore way and filling. The second accident occurred through the fall from the roof of about 12,000 tons of ore, which crushed over 30 bulkheads that were under it. The square-set system of mining, which has been in use in the older parts of the mine for the last 20 years with very satisfactory results as regards safety and economy will be adopted throughout the mine in future. The flat-back stope or chamber system, which had been introduced as equally safe but more economical, will be discarded. In practice it was found that the cost of this system of mining was identical with that of the older system.

At the gold reduction works 123,675 tons were treated, averaging 6.41 dwt. or 27.22s. per ton. The total recovery was 39,717 oz. fine gold. On sulphide ore the cost of crushing, roasting and chlorinating was 13s. 7d. per ton and on the oxidized ore these costs were 10s. per ton.

At the smelting works 102,575 long tons of ore and middle products were treated, the value of the copper ore being 8,371 dwt. gold and 3,475 per cent. copper. The matte produced averaged 45 per cent. copper and went directly to the converters, which produced 3,655 tons of blister copper, containing 3,625 tons copper and 47,005 oz. gold.

It is said that discussion of the proposed new mining law will be resumed at the session of the Mexican Congress beginning April 1, 1909.

Geology of the Guanajuato District, Mexico

Cretaceous Shales Are the Oldest Rocks; Intrusions, Faulting and Brecciation Are Characteristic Features; Orebodies Occur along Fault Zones

B Y C. W. B O T S F O R D *

The Guanajuato district has come so rapidly to the front in the last few years and is becoming so well known, that it seems to me that a general geological description of the camp with some notes on the veins and ore occurrence is of interest. The accompanying plan and cross-sections should make it easier to follow the relations of the various formations. These plans are taken from work done by the Guanajuato Development Company and are largely from actual surveys.

TOPOGRAPHY

The Sierra of Guanajuato is one of the low detached mountain ranges which rise above the central plateau of Mexico. The erosion has been so extensive that the topography of the country gives little indication of the folding and faulting of the district. The principal mines of the camp are on the western slope of the mountains, with the drainage outlet through the Silao valley. On the eastern slopes of the mountains are the smaller camps of San Felipe or Providencia San Juan de La Luz, Santa Rosa, and San Antonio. The physical conditions in these various camps are the same as at Guanajuato proper and should be considered in a discussion of the Guanajuato district.

CRETACEOUS SHALES

The oldest exposed rocks in this whole section of the country are the Cretaceous shales. These are usually black, thinly and irregularly bedded and are calcareous. A few of the more highly calcareous beds are quarried and burned for lime, but these beds usually carry sufficient aluminous matter, to give the product weak hydraulic properties. In local areas of the district metamorphism has produced from the shales, sericite and quartz schists. These areas are, however, rather rare. Beds of impure limestone appear in the shales in increasing percentages at the extreme north end of the district. These shales have a thickness of at least 3000 ft., shown on the Valenciana. The total thickness is not known as the underlying strata have yet to be penetrated. Complex minor folding, followed by extensive erosion has affected these shales, and left a very marked unconformity between them and the overlying eruptives.

GUANAJUATO CONGLOMERATES AND LA LUZ SCHISTS

Following these shales is a long series of andesitic breccias and tuffs cover-

ing the entire Guanajuato district. These were probably from more or less continuous explosive volcanic eruptions falling into shallow lakes or an inland sea. In large areas, a regular arrangement and bedding can be traced for miles. In other local areas, the arrangement and bedding are both irregular and the beds pinch out sharply. This formation, to my mind, could only have been formed under the shallow sea or lake conditions, the regular bedding being the portion of the formation formed in the deeper and quieter waters, and the irregular bedding being at or near the old water-levels. Parts of the area, showing the most irregularities, were probably above the water at this time. These andesitic breccias are about 3000 ft. thick in the central portion of the district. At La Luz, and to the north, this formation gets thicker, but how much is not as yet determined. These beds have been extensively metamorphosed, and lose their original characteristics entirely. The upper part of these beds has been consolidated into an agglomerate of a deep purplish-red color which is called locally the Guanajuato conglomerate.

This rock, I think, shows water-action very plainly, over the larger part of the area; this action has resulted in the rounding of the fragments and the bedding arrangement. Lower down in the formation, where the metamorphism has progressed farther, there are many varieties of schists, slates, and many unnamed, hard, indurated, close-grained rocks. Locally these are called the La Luz schists. Properly speaking, these are not true schists, but vary much in character in different portions of the area. Probably 20 per cent. of the rock mass shows more or less schistosity. These schists have their greatest development in the La Luz portion of the district, hence the name. The transition from the agglomerates into the schists is marked by no sudden change; the agglomerate first loses its original red color, then the beds show all gradations into the final schist, in which all trace of the original fragmentary structure is lost.

GRANITE INTRUSION

In the La Luz portion of the district, there is an extensive granite intrusion, which was subsequent to some or most of the regional metamorphism of the La Luz schists. This intrusive body has been exposed by erosion over all the country from San Cayetano and Nueva Luz to the northwest for about 8 miles and as far

east as the Mother lode. This granite is remarkable for the large percentage of schist inclusions. There is no regular contact between the two rocks, but the granite has intruded itself between the layers of schist, breaking and turning them up in all conceivable forms and shapes. Tongues of schist varying in thickness from a few inches to many feet and hundreds of feet long are of common occurrence. Irregular fragments of schist, included in the granite mass, are found in large percentages in nearly all parts of the intrusion. This gives to the contact a form as of interlocking fingers, mixed with innumerable fragments and boulders of schist. In only a few places that I have seen is the granite at all free from these inclusions. These probably indicate points nearer the center of the mass. Buenavista mountain seems to be the principal source of the granite because of the great thickness of the intrusion here (over 2000 ft.). The granite originally extended several miles to the west of La Luz, and, except on a few of the higher ridges, has been removed by erosion. This may have been a sill extending out from the body of the intrusion.

The granite becomes more hornblendic toward the interior of the mass. Usually at and near the contacts, there has been a strong basic differentiation resulting in diorites and quartz-diorites. In many places these dioritic differentiations seem to be broken into fragments, and slivers, showing sharp contacts with the normal granite which frequently surrounds them. This, I think, must indicate a partial solidification of the first magma and a further injection of more granite. Much contact metamorphism has taken place with the formation of much epidote and some tourmaline. Because of the mixed nature of the contact, it would seem that the intrusion must have been against great weight, only explainable by the former presence of overlying formations.

The succession of rocks above the schists is a series of andesitic and rhyolitic breccias, which were both probably needed to give the necessary weight. For this reason I have placed the age of the granite as possibly among some acid eruptions coming before the later rhyolites.

DIORITE INTRUSION

There is also, at La Luz, considerable evidence of a dioritic intrusion before the granite. Metamorphism has been so extensive, and weathering has so altered the exposed rocks that it is impossible to de-

*Mining geologist, Guanajuato, Mexico.

termine what many of them are. It is probable that only future developments in depth, in the mines, will settle the question of the exact character of many of the lower rocks of the La Luz formations. This part of the country was undoubtedly the center of the volcanic intrusions, which played an important part in the mineralization of the Guanajuato district.

It is impossible to give the extent and thickness of this dioritic intrusion, as it is too poorly exposed. In fact, I am led to infer the presence of an extensive diorite intrusion, more from observations at other places, as Zacatecas and Etzatlán, Jalisco, than here. At these localities the so-called Guanajuato conglomerate has been penetrated by diorites and well exposed by erosion. Near the intrusion, the phases of alteration and metamorphism

miles to the south of the city and here disappears under the overlying formations. This sandstone is undoubtedly a strictly local formation. This conformity between the andesitic and rhyolitic rocks indicates a country in a quiet stage as far as folding or faulting was concerned, and probably a slowly sinking one.

PINGUICO RHYOLITES

Following this Bufo sandstone is a series of eruptions of rhyolitic breccias called the Pinguico rhyolites. This is an exceedingly important formation, as it is the repository of some of the largest and richest orebodies of the district; notably those of the Pinguico mine. This formation has a thickness of about 3000 ft. at the mine, but thins out rapidly to the east

have overlain the country to a depth of about 3000 ft., reaching their greatest development to the south of the city of Guanajuato. This formation was made by innumerable small eruptions, or a closely continuous great eruption, as the beds are very thin and of great numbers. Among these are several tuffaceous beds forming probably 10 per cent. of the formation, called the Calderones tuffs from a small town of that name in the district. These tuffs and breccias have been consolidated, but not very thoroughly, leaving a soft, porous rock which has later been very much altered by decomposition. They have not produced much ore, being as a general thing above the ore-bearing horizon, and in most of the district entirely eroded.

Between this formation and the Pin-

GEOLOGICAL MAP AND CROSS-SECTIONS OF THE GUANAJUATO DISTRICT, MEXICO

have formed rocks precisely similar to many of the La Luz schists. The age of this intrusion is probably about the same as some andesitic intrusions which came before the later rhyolites, but later than all the other extensive eruptions here.

BUFO SANDSTONE

Overlying this andesitic agglomerate formation, and conformably is a thin bed of rhyolite tuff. This has been deposited in regular layers, showing the sorting action of water. It has been consolidated into a rock called the Bufo sandstone. This has been extensively quarried for use in the city, and for shipment, as it makes a good building stone, easily quarried and worked. This formation has a maximum thickness of about 40 ft., but pinches out to the east and north of the city of Guanajuato. It extends also about 6

and north; to the south the formation is of unknown extent. The rock itself is a very acid rhyolitic breccia, which has been consolidated into a rock showing only traces of its original brecciated structure and hardly distinguishable from an original massive rhyolite. One thin bed at the extreme base of this formation is different; it looks like an eruption of volcanic bombs. Near the top of the formation the material becomes more and more tuffaceous, and is not as much consolidated as the lower beds. These rhyolitic breccias are perfectly conformable with each other and with the underlying Bufo sandstone, thus proving a continuation of the quiescent period.

ANDESITIC TUFFS AND BRECCIAS

Following the Pinguico rhyolites is a series of andesitic breccias and tuffs which

guico rhyolites is perfect conformity, except in a few local instances, where there is a sudden thinning out of beds, and a general disarrangement as though these were small local areas which were near the level of the sea. The general regularity of this formation shows the continuation of the period of quiescence, and the above local ununiformities indicate, I think, the slowly sinking sea bottom with the occasional local area building up near the surface of the water.

This formation contains many intrusions of massive andesite in laccoliths and radiating sheets and dikes. These cut through the underlying formations, but their principal development has been in the andesitic breccias. These intrusives seem to have had absolutely no influence upon the ore occurrences.

Following these breccias came a period

of uplifting and subsequent erosion. There were two principal uplifts, one, the smaller and probably the older, which passes about through La Luz has an east and west axis. The other, or principal anticline, has a northwest and southeast axis and passes from just west of Pinguico toward and about through La Luz.

LATER RHYOLITES

After this uplifting came many eruptions of rhyolite tuffs and breccias and some massive flows which are called the Later rhyolites. These lie unconformably over the older eruptives. Erosion has removed practically all of this formation, the only exposure left being on the top of Chichindaro mountain. East and north of Santa Rosa, however, the formation still remains, and is several thousand feet thick. The rocks are generally normal rhyolites, but show a tendency to grade into trachytes and dacites in local areas. In some of the extreme northeastern parts of the district are a few recent, small eruptions of a black, usually cellular olivine basalt.

FAULTING

The faulting in the Guanajuato district has been extensive and is complicated in sections. In a general way, there are three well defined systems of faultings, of which the first two were closely contemporaneous. The main system or Mother-lode system, probably occurred by relieving the strains caused by the settling of the uplifts already mentioned. These faults form a parallel series, with a strike of north 20 to 40 deg. west and a south-westerly dip varying from 45 to 55 deg. The movement on this series has been very extensive, probably 6000 ft. or more, of which the Mother lode has given about 3000 ft. These are all normal faults and have always moved to throw the bulk of the uplift downward. These are not simple faults, but rather zones of faulting, which, in some places on the Mother lode, are as much as 300 ft. wide, and show as many as five distinct large slips, and a multitude of smaller ones. This faulting occurred through a long period of time, during the latter part of which the mineralization was in progress.

The second system of faulting has an average strike of about north 60 deg. west, and is usually nearly vertical in dip. This, I think, occurred to relieve minor strains along the first large system of faults and is necessarily of the same age, or slightly later. They usually intersect the Mother-lode system at angles of 30 to 60 deg. In any one part of the district this system of faults is usually parallel. Of course, all these faults do not conform exactly to the above two systems, as any local conditions affecting the strains or resistances of the rock-mass would cause local variations in the faulting. The two notable exceptions to the general systems are the Bolañitos and San Carlos

veins. These are parallel to the Mother-lode system, but have an opposite dip.

The third system of faults was much later than the others and displaced them both. They are of very little importance, as they are few in number and are not sufficiently mineralized to be of value. The largest known is the Cardones fault with a displacement of about 300 feet.

HISTORY OF THE VEIN FORMATION

As far as it goes, a description of the faulting in this district is a description of the veins, as the ore-bearing solutions have invariably followed the lines of fracture and faulting. The ore deposits are invariably replacements of the country rock with a very little open-cavity filling. These replacements are localized along the crushed zones and the intersections of the faults, and have extended into the wall rocks where the conditions were favorable. The history of the vein formation in the district has been: (1) The formation of fault fissures with the accompanying brecciation and grinding along the walls. Without these fault fissures giving an outlet to the deep-seated solutions, the mineralization of the district would have been impossible. (2) The ascending of the mineral-bearing solutions and the deposition of mineral by replacement in the most favorable localities. (3) A further faulting, some brecciation of the vein-filling already deposited and a continuation of the ore deposition.

These lubrications show a succession of periods of comparative quiescence followed each by a resumption of the faulting and brecciation. This has been accompanied by changes in the composition of the mineral-bearing solutions. I have not worked out the succession of these changes, but in general the principal ores occur in the first; the latter are highly silicified and contain low-grade ore. Amethyst quartz and part of the calcite were among the last minerals deposited.

ORES

The ore contains gold and silver in varying proportions; the gold content is about one per cent. of the silver. The silver is almost entirely in the form of argentite and usually intimately associated with quartz. In some of the mines there is occasionally a little pyrrargyrite and proustite and some of the rarer silver minerals; in some of the upper workings the chlorides and bromides are found. The gangue is quartz and calcite; other minerals occur only rarely; pyrite is quite abundant. Of copper, lead and zinc, only traces are found. The ores, except locally and near the surface, show no signs of secondary concentration or even of oxidation.

ORE DEPOSITS AND INFLUENCES OF WALL-ROCKS

The ore deposits are found impartially in all of the formations, but vary in char-

acter according to the wall-rock. In the shales the orebodies are usually a mass of stringers or *ramaleos* running in all directions through a brecciated mass of shales which are in all stages of replacement. The principal orebodies are usually where these stringers have united and form a solid mass of vein matter. In the La Luz schists this same occurrence of *ramaleos* is very characteristic. The ore in some of the stopes seems to be merely a zone of these stringers although the principal orebodies are usually in the harder quartz. In the conglomerate the veins are harder with usually higher gold content. Replacement seems to have been slower and more difficult in this rock except where it had been thoroughly brecciated.

In the Pinguico rhyolites the solutions seem to have found a rock especially adapted to the action of replacement. The ores here are the clayey remains of the feldspar with quartz and usually high in silver and gold. In places the original walls of the vein are destroyed and the mineralization has extended into the country-rock until it is only by sampling and assaying that the limits of ore can be defined. It is in this formation that the large orebodies of the Pinguico and Carmen are found.

In the overlying andesitic tuffs and breccias very little ore has been discovered. This is due, principally, to the fact that this formation lies very high in this district and that most of the orebodies simply did not rise to this horizon.

The granite seems to have been too hard and tight to have allowed of the formation of strong veins. The diorite intrusions in other parts of Mexico have been exceedingly favorable for the formation of ore.

GENESIS OF THE ORE DEPOSITS

I am inclined to place the cause of the anticlinal uplifts to an extensive intrusion of a dioritic magma which had its central mass near La Luz. This probably caused some of the extensive metamorphism which has so markedly affected the La Luz district. The weight and subsequent settlement of this intrusive mass probably caused the breaks and faulting parallel to the Mother lode. The unequal temperatures of the intrusion and the surrounding rocks would tend to create a circulation of the underground waters toward the intrusion, and thence upward through the fault fissures. These waters under the great heat and pressure would take into solution, in the order of their solubility, whatever metals or minerals they came in contact with. As these solutions rose through the fissures they gradually cooled and the pressure decreased, thus lessening the solvent power of the water; the more insoluble burdens were deposited in place of the more soluble materials they came in contact with. The first solutions were highly alkaline and showed a strong tendency to replace

the quartz-bearing rocks with which they came in contact, as in the Pinguico mine, and other deposits in the rhyolites. The later silicious solutions were probably the final result of the granite intrusion, as was also the continued faulting and brecciation of the previously deposited vein matter.

In a general way, I think the above is a correct explanation of the genesis of the ore deposits here. I am led to feel very certain of the assumed dioritic intrusion from observations at other camps, mainly at Zacatecas where the Guadalupe arroyo has cut across both the conglomerate and the intrusion. The metamorphic products are exactly the same and the gradation rocks the same as at La Luz only on a very much smaller scale.

Several books might be written here on the details of the metamorphism, faulting, and ore-occurrences, etc., but I think the above article gives a general idea of the district without being of undue length.

The American Prospector in Mexico and His Problems

BY THORINGTON CHASE*

The same spirit that launched the overland prairie schooners upon their long western journey in 1849, somewhat modified by reason and caution, is today sending prospectors into Mexico in great numbers. The majority of these are young men fresh from the mining schools, and it is chiefly for their benefit that this article is written. A minority are older men, hardened by years of experience in the mining districts of the West, and inured to many of the hardships encountered in Mexico's mountains. As a rule, they have acquired enough Spanish to enable them to conduct their affairs without the aid of an interpreter, and to handle peon miners where necessary. Moreover, they find no difficulty in adapting themselves to the rugged conditions of Mexican life as they require no luxuries, and but few of the necessities.

A good working knowledge of the Spanish language is one of the requisites for a successful young mining engineer in Mexico. Many of the young graduates whom I have met do not possess this. The legal proceedings incident to the denouncement of mineral claims, while simple enough in themselves, will not only involve one, ignorant of the language, with cunning lawyers, but will often lay him open to extortion. A brief summary of the Mexican mining laws will show the many pitfalls for the unwary.

MEXICAN MINING LAWS

The Mexican mining claim, or *pertenencia*, is 100 m. square. Five *pertenencias*,

slightly exceeding in area the American mining claim, is usually the minimum denounced, although in the richer auriferous district, single *pertenencias* are held and worked. The law permits denouncements of mineral claims on either public or private domain, but in the latter case, prohibits the use of standing timber, or of other superficial resources. Reasonable ground for dump and mine buildings may be arranged for with the land owner, at assessed value, or in case of his refusal, can be condemned for that purpose by due process of law. Building stone, oil, coal and placer ground are held as the inalienable property of the land owner, and hence cannot be denounced on private lands. Further changes in this law are looked for shortly.

LOCATING CLAIMS

After locating mineral, the prospector first makes out his application. This must give the general location, stating what ground is wanted, its shape, and the direction of its boundary. This application is then filed in duplicate at the Oficina del Timbre (to be found in every mining district), and with it must be deposited \$5 for each *pertenencia*, if the number be 25 or less. For denouncements of over this number of contiguous deposits, \$3 per *pertenencia* is required. A 50c. stamp must be affixed to the original application, irrespective of the number of units of land applied for.

It is important that the prospector name the surveyor whom he has engaged for the subsequent survey, for in case no one is named the Government is obliged to appoint someone within eight days, and this appointee may prove unsatisfactory to the prospector, or may charge exorbitantly for his services. Forty days are allowed for the prospector to complete his survey and draw the plans for the same. Prominent and well known natural monuments, such as the highest neighboring peak, must be used in describing the survey, and all adjacent claims and "free ground" clearly shown and marked upon the plan. During this period the prospector must also publish a notice of his denouncement in the official newspaper of the state in which his claim is located.

Plans and survey records must be filed in triplicate (one copy being returned later upon grant of title), and the same remain with the local mining agent for a period of four months from the date of filing of the application, upon the expiration of which either the title is assured, or the application rejected. Upon receipt of the title the prospector is called upon to pay \$1 for each *pertenencia* if the number be 25 or less, or 50c. per *pertenencia* if the number exceeds 25. A yearly tax of \$5 for each *pertenencia* is exacted, being payable in equal instalments every four months.

The expenses incident to several denouncements, as well as the initial outlay

in mining operations, are high, and the graduate, trusting to technical education to make his way as a prospector in Mexico, and thinking it easy to secure a good position in one of the numerous centers of Mexican mining industry, is liable to find himself stranded and lucky to secure a position carrying with it probably \$50 gold per month. As a rule experience, rather than theory, is the qualification for the mining engineer in this country.

However, the opportunities for the young American mining engineer in Mexico are great. The vast deposits of calamine, only so recently recognized, the wealth of gold, silver, lead and copper, plentifully scattered throughout the states of the republic, are but in the infancy of their development along modern lines. The prospector, however, should be equipped with a knowledge of Spanish, and, above all, capital is required to develop any property. The prospector usually overlooks this most important point.

Energy of the Blow in a Coal Puncher

One of the most important factors which determine the energy of the blow struck by the pick of a coal puncher is the rate of admission of air to the cylinder. In the usual type of compressed-air machine the admission of air is subject to restrictions of delivery from the various channels, such as valves, pipe or hose leading to the machine, etc. The ports must, therefore, remain open an appreciable length of time in order to permit the air to flow into the machine, and the forward stroke is accordingly retarded. The energy of the blow which is due to the speed and weight of the striking piston is expressed in mechanics as follows:

$$\text{Energy of blow} = \frac{mv^2}{2g},$$

in which m is the weight of the moving body, v the velocity and g , 32.16.

The manufacturers of the Pneumatic machine claim a more powerful blow than that of the ordinary compressed-air coal puncher by reason of a more rapid admission of air and a stroke of higher velocity. From an examination of the formula it will be seen that with the same weight in pistons, the energy of the blow mounts rapidly with an increase in velocity, thus the blow is 50 per cent. more powerful with only 22½ per cent. higher velocity, or 25 per cent. more powerful with 12 per cent. more velocity. This higher piston velocity with a given quantity of air, and reduction of compressed-air transmission losses are among the claims put forward by the manufacturers for the higher efficiency in the Pneumatic machine.

*Chemical engineer, Concepcion del Oro, Mexico.

Cyanide Lixiviation by Agitation

BY WALTER M. BRODIE*

After it has been established how fine an ore or product has to be ground in order to liberate the mineralized metals, the next point is how to treat the ground pulp. Generally the ground ore cannot be leached by percolation because it contains too much clay or slimes, and cannot be treated by agitation because it contains sands. It has, therefore, to be classified into sands for percolation and slimes for agitation.

Percolation is a comparatively cheap process, but it is slow and in large vats, especially when the ores are rich in silver, often gives irregular results, owing principally to the uneven distribution of the fines among the sands, which produces an uneven circulation and a lack of aëration. When, after a certain number of days or weeks, the extraction stops, almost always the assays vary in different parts of the vats, and the lower layers of the leached ore in the vat are considerably richer than those near the top. This often necessitates repeated shoveling over and re-leaching.

Agitation, as generally performed with centrifugal pumps and mechanical stirrers is expensive and not always thorough, as the coarse slimes, or rather the fine sands contained in the slimes, settle in some parts, fail to be stirred and, therefore, do not give up their gold and silver.

Now any ore which can be cyanided, either sands, slimes or concentrates, will give up its gold and silver quickest if it be well shaken up. This can be done most effectively in a revolving barrel, because there every particle of the mass is put in motion and the surfaces of each are being scrubbed clean continuously. A barrel plant, however, unless it be for concentrates or for very rich ores would be too expensive for a large tonnage. Very likely, however, in course of time when the tube mills become out of date for fine grinding, the shells of the old tube mills will be used for cyaniding concentrates.

THE PACHUCA TANK

The next best mode of stirring and one which is finding favor rapidly, is the agitation by air through a central air lift in the high cone-bottomed or Brown tank, introduced in Mexico under the name of the Pachuca tank. Like any other, this process has its limitations, but on account of its simplicity, comparatively low cost and great scope it very likely will be generally adopted.

The air introduced at the bottom into the central lift tube throws up or blows out a part of the column of water contained therein and this establishes a strong upward current if the liquid on the out-

side of the lift pipe has free access to the bottom. When thin slimes are being worked this will generally be the case, but when the bottom of the tank is filled with anything that impedes quick filtration, say, with a heavy bed of fine concentrates, or with a settled mass of ground ore containing vein clay and sands, the circulation is apt to give trouble. To avoid this trouble the circulation pipes, shown in the sketch, may be used with great advantage. These pipes lead solution from above to within so short a distance from the entrance of the lift that the surplus pressure of the

pipes, sands can be circulated, and the circulation will keep up, even if the sands are so heavy and abundant that the cone never gets clear.

DETAILS OF THE IMPROVEMENT

The combined area of the circulation pipes should be about one-half of the area of the lift pipe. They can either be fastened to the lift or they can be fastened to the outside wall of the tank. The latter arrangement has some advantages.

The most effective point of discharge depends somewhat on the material, but

PACHUCA TANKS WITH CIRCULATION PIPES

column on the outside of the central lift pipe must wash away instantly the accumulated material below their lower openings. In a tank in which the material has settled, as soon as the air is turned on, the liquid passing through them clears away everything in the apex of the inverted cone and allows the accumulations to sink down; and as the pipes furnish constantly a free supply of liquid, they regulate the quantity of the heavier accumulations. As soon as the cone is clear they stop the fast flow, ready to furnish water for flushing as soon as there is any obstruction from accumulations. With these

varies from 6 to 18 in. above the entrance to the lift according to the size of the tank and the material to be treated. Three or four pipes may be used, according to the number of braces with which the lift pipe is attached to the tank. The circulation pipes bring the water from the upper part of the tank. Their upper end should be fitted with return elbows so that stuff loaded into the tanks, or the coarse settlements thrown up by the lift may not fall down the pipes. The great advantage of the circulation pipes is that a much larger proportion of sands can be stirred effectively than in any other of the customary

*Mining engineer, Batopilas Mining Company, Batopilas, Chihuahua, Mexico.

agitation vats; that even concentrates can be effectively put in motion and that starting of the movement takes much less air and much less power than when a heavy and thick mass has to be put at once into circulation.

Any cyanide expert will admit that an effective and cheap way of stirring and scrubbing sands will not only accelerate the extraction of their gold and silver, but also will save chemicals, reduce the size of the plant and cheapen the process. The tendency in cyanide practice has lately been toward sliming everything, but sliming everything is expensive. If once the sands are ground to such a size that they disclose their gold and silver, it is cheaper to wash them than to grind them fine into slimes. The extraction of silver and gold from concentrates is at present a matter of much experimenting. As a thick bed of fine concentrates does not filter, the circulation pipes in an air-lift tank may often produce the required agitation, which without them it might be impossible to maintain.

Borax in Assay Fluxes

By J. E. CLENNELL*

Experimental work carried on throughout a period of six months on a typical free-milling ore presenting no special features of difficulty led me to form certain conclusions regarding the use of borax in assay fluxes. The investigation was undertaken mainly on the following grounds:

(1) The fluxes previously used in assaying this particular ore had not given entirely satisfactory results.

(2) Statements had been made that the use of borax as an assay flux is liable to give rise to serious losses. It was thought worth while to test the latter point experimentally on a quartzose ore practically free from base metals except iron.

The iron was present almost exclusively as oxide, in varying amount.

The chief points noted in the course of these tests were the following:

(1) The use of a large excess of borax has a tendency to produce a hard stony slag very difficult to separate from the lead: when touched, especially with a sharp instrument, it sometimes flies to pieces with explosive violence or suddenly crystallizes in radiating needles; a film of lead almost invariably breaks off the button and adheres to the slag. This detached lead can only be recovered with much labor and some portion is probably always lost in hammering out the buttons.

(2) When no borax at all is used in the flux, the button separates absolutely clean from the slag, so that in some cases it can be cupelled direct without even hammering out. While cooling in the molds a scum rose to the surface, which on closer examination was seen to consist of a

network of straw-colored crystals, evidently resulting from some constituent of the ore which remained unfused in the absence of borax.

(3) The presence of borax made the charges distinctly more fusible and gave, usually, a clear greenish slag. By using a small quantity of borax in the charge, not exceeding 5 to 10 grams per a.t. of ore, it was found that a uniform fusible slag was produced without any noticeable amount of the scum, and that the buttons could be detached from the slag by a slight blow, without any portion of lead adhering to the slag.

(4) The slag became more deliquescent as the proportion of borax was diminished. This deliquescence is a disadvantage only when hammering out is delayed for some cause or other, as when a batch of assays is left in the molds overnight.

In a series of tests, one assay of each sample was made with a flux con-

Practice in Mexican Cyanide Mills

BY MARK R. LAMB*

The accompanying table gives a condensed record of cyanide practice in Mexico as exemplified in the equipment of the principal metallurgical plants using this method of extraction. The data covers the operations of over 20 leading establishments, and it is interesting to note the steady advance of certain of the newer features of cyanide practice.

Battery and Cyanide Costs

The following figures on the costs of battery and cyanide work in western Australia and on the Rand are taken from the *Aust. Min. Stand.* of Dec. 9, 1908: West Australia—Golden Ridge, milling, 2s. 7.6d. per ton. Ivanhoe, milling, 2s.

taining no borax, and another assay with a flux as similar as possible, but containing borax. The fluxes were adjusted so that the total weight of the fusion charges and the quantities of charcoal were the same in each pair of assays.

Taking the results as a whole, it may be said that they show no marked advantage either way; they lend no support to the idea that borax carries any appreciable quantity of gold into the slag. Any losses of gold which may occur through the use of too large a proportion of borax seem to be due to mechanical causes, chiefly to the breaking off of small portions of the lead button in the process of hammering out, owing to the adhesion of the lead to the slag.

The addition of a small amount of borax seems, however, to be a slight advantage, perhaps chiefly on account of the greater fusibility which it imparts to the slag.

A Trip Through Northern Durango

By C. N. NELSON*

In the spring of 1908 I had occasion to make a trip through northern Durango. The roads to Indé, Guanacevi and Magistral from Rosario are shown in the accompanying sketch map. They are all wagon roads in more or less good shape, though the road to Guanacevi is only open for wagons as far as Tule.

From Rosario it is an easy ride to Los

other silver, lead, and copper veins; to the south, the Mina de Agua and several other lead-silver mines. There is practically no known mineral ground in the surrounding country farther than 4 or 5 miles from the Bufo.

MINES OF INDE

The Terrible mine of the Indé Gold Mining Company has a compact little plant, mine and cyanide mill, and treats 50 tons and upward per day. The ore occurs on a contact between porphyry and a great limestone reef which cuts across the country and can be traced for 5 or 6 miles. The ore is very silicious and is

lupe, has a 125-ton copper stack which is run intermittently on custom and company ores. The company ships 13-per cent. copper matte to Rosario, at a cost of \$10 per ton; coke on the return trip costing \$7.50 per ton freight. The coke is said to cost \$35 per ton delivered; wood, \$2.50 per cord, and the smelting cost comes to about \$14 per ton. The scarcity of copper in the ores and the high freight costs keep the operations on a small scale.

EL ORO AND GUANACEVI

From Indé to El Oro is about 18 miles over an old wagon road. This camp was

MILL, GUANACEVI COMPANY, LTD.

MINES AND MILL, SAN PEDRO, GUANACEVI

SMELTERY, MAGISTRAL, DURANGO

TERRIBLE MILL, INDE

Sauces where one can put up for the night and reach Indé early the next afternoon. A wagon with relays of mules can make the trip in one day, but with saddle animals it is unwise to attempt it. Indé proper is a quaint little town nestled in a narrow valley. It is the commercial center of the surrounding agricultural country, and is about 6 miles from the mines.

The mines of the Indé district are all situated in a ring about a great *bufo*, or butte, which rises out of the low hills like a huge monument. On the northern slope are the Terrible and Guadalupe gold deposits; to the east, Los Colorados and

said to average at the mill about 1 oz. gold per ton. The mill saves about 85 per cent.; and the mining costs are about \$2, and milling about \$5 per ton.

The adjoining mill of the Guadalupe Consolidated Mining Company is an extremely simple plant with no machinery except in the crushing department, but making the same saving as the Terrible mill. The two companies have a quantity of ore blocked out, 30 ft. wide in places, said to average 0.5 oz. gold per ton.

The other mines of the district are not as far advanced as these two, but one or two look promising. Transportation difficulties are holding back the development of the camp. The Indé Reduction Company, about two miles south of the Guade-

once the center of mining in the district, but now there are no mines operating nearer than Magistral, three miles farther on. Here the Lustre Mining Company has been operating for about 25 years, owning now several mines and a 200-ton smelter. The company has three 36x168-in. furnaces with a charcoal gas-power plant. The ores are concentrated about 20 to 1, and the 15 per cent. matte, high in gold, is shipped through Rosario. The coke costs \$25 per ton, which includes the wagon freight on the matte shipped out. The average price of labor here is 75c. per day. The plant was not running at full capacity.

The old Wilson wagon road between Guanacevi and Jimenez passes through

*Mining engineer, Buffalo, N. Y.

El Oro. The trip from there to Guanacevi is made in two days, a 20-hour ride, passing the ranches of Tinaja and El Pueblo, to Zape on the present route for wagons from Guanacevi to the railroad at Tepehuanes. The country is rough and heavily wooded. The *rancheros* bring in all sorts of ore samples, a few of which look promising.

Guanacevi is an old mining camp, a monument to the faith of stockholders. Passing up the arroyo toward San Pedro, one sees the ruins of plants of almost every known process for the extraction of silver, from the patio through chlorination, pan-amalgamation, smelting and cyaniding. There must be at least 30 plants idle or in ruins, representing the outlay of an enormous capital. The boom days were in the early nineties. Guanacevi contains a great number of narrow veins; most of these consisting of a silicious vein filling with high-grade pay streaks of argentite, ruby silver, and a little native silver. Some of the veins are wider and contain zinc and lead sulphides, running lower in silver. A few small shipments have been made running as high as 1500 oz. silver, and perhaps 20 oz. gold per ton, but such are rare, and from 150 to 300 oz. silver is the usual assay of the shipped ore. All below 30 oz. is generally left on the dump.

The Guanacevi Company, Ltd., is operating some of the former good producers, and is employing about 250 men. The company has modified the old mill and is running it with the cyanide process, on heads of about 30 oz. silver.

OTHER MINES IN THE DISTRICT

About five miles northwest of Guanacevi is San Pedro, a level valley where the Mexican Consolidated Mining and Smelting Company has its mines and mill. A 100-ton concentrating plant has been running more than a year, shipping high-grade concentrates and impounding the tailings. After considerable experimenting, a 200-ton cyanide mill has been erected to re-treat the big tailings dump with a certain proportion of fresh ore. The plant is modern in every particular. Everything is to be slimed through tube mills.

Two or three small mines are running successfully under Mexican ownership, and some of the old producers are working in a small way under lease. Several of the larger mines are almost hopelessly tied up in litigation, and others by disagreement among the stockholders.

One or two small mills are buying custom ore, charging \$10 per ton treatment, and paying for 70 per cent. of the silver and 50 per cent. of the gold. They probably save about 80 per cent. of the silver and most of the gold. Until the start of work in San Pedro, the camp averaged for a number of years, perhaps 20 tons of mill ore daily and \$250,000 of shipping ore a year. The charges on shipping ore run about as follows: smelter, \$8

to \$10 per ton; wagon freight, \$12.50; and railroad freight \$7.50; a total of \$30 per ton. Labor costs from 75c. to \$1 per day. The camp is really a high-grade one with consequent low tonnage.

Returning by direct route to Rosario, one travels over a wagon road which could be repaired at small cost. Tule is the half-way stop, near which the road to Carmen branches off. This camp was once active, but is dead at present. Guadalupe y Calvo and Topia are west of Guanacevi, and are still too far from a railroad to be very active.

Railroads to enter the district are possible from two sides of both Indé and Guanacevi. The most likely to reach Indé is one from Las Cruces, giving a direct line to Torreon; while the International is likely to build up from Tepehuanes, or

Mexican Producer Plants

The general adoption of producer gas in Mexican mining operations is well illustrated by the plant of the Capuzaya Mining Company, Parral, Mexico. Here a 300-h.p. Westinghouse gas engine generating unit was put in operation in February of the present year, operating on power gas generated from charcoal. This plant was installed to serve a large group of mining properties at Parral. The National Iron and Steel Company, Mexico City, has also operated a producer gas engine plant for light and power service, and the Cia. Industrial Jabonera at Laguna, Mexico, installed a similar plant in 1906. Another important plant in Mexican territory may be mentioned, that of the Potosina Elec-

SKETCH MAP, NORTHERN DURANGO, MEXICO

the Parral & Durango down from Mesa Zandia.

In *Dingler's Polytechnisches Journal* for Sept. 15, Professor Freytag, of Chemnitz, expresses the opinion, as abstracted by the *Min. Journ.*, that turbo-compressors are superior to piston machines in point of oil consumption and simplicity of attention, and also because there are no moving parts except the vane shaft, and no shock or reversal of the direction of force, all valves and valve gear being also dispensed with. An automatic circulation of lubricating oil prevents waste; and since no oil can find its way into the casing, the machine furnishes air uncontaminated with oil. The space occupied is small, and the working speed and the volume and pressure of air can be varied between wide limits.

tric Company, San Luis Potosi, Mexico. This was one of the earliest and the largest installations in this part of the country, the first engines being installed in 1902. Another is that of the Empress Electricita Duraguena, Durango, Mexico, in whose plant is installed 320 h.p. in suction producers.

The *Queensland Gov. Min. Journ.* for Jan. 15, 1909, publishes a formula for a protective coating for cyanide tanks which may, it states, be relied upon. It is made by heating 80 lb. of tar in a water bath at 100 deg. F. until all water is evaporated, and then adding, with constant stirring, 80 lb. of natural cement hydraulic lime. The mixture should remain fluid and be applied hot. No quicklime should be used.

Mining in the Alamos and Arteaga Districts

Review of a Rich Section of Northwestern Mexico where Production Will Soon Be Stimulated by the Operation of New Lines of Railroads

BY GEORGE M. BLOOMER*

The Alamos is the oldest producer, yet withal the least known district in the State of Sonora. It is the southernmost district of the State and is bounded on the west by the Gulf of California, on the north by the Yaqui river, by the Arteaga district on the east, and on the south by Fuerte district of Sinaloa. For 250 years Alamos has been a producer, and the church and mint records credit it with a production of over \$500,000,000 in silver and gold—chiefly silver up to 1895. About nine-tenths of the production was made prior to the French occupation in 1864. In 1800 Alamos had 84 producers of record, but the location of only 15 of these *antiguas* is known today. With reference to the silver deposits, it is a question if modern practice and methods together with the recently acquired transportation

sub-divided into three great belts or contacts running approximately north and south. What I shall call contact No. 1 is the most westerly of these and consists of an intrusive porphyry dike about 35 miles long and from $\frac{3}{4}$ to $3\frac{1}{2}$ miles wide with the greatest width at Minas Nuevas, $\frac{4}{5}$ miles west from the city of Alamos, the metropolis of the district. Here is located the famous Zambona mine of which John Hays Hammond was in charge during the earlier period of his career. The Zambona is the most northerly of a group of famous *antiguas* of which the Zambona and Quintera are the only ones under actual operation today. The old mines on the contact, beginning at the southern end, are the Balvaneria, the Promontorio, the Quintera, the Paloma, the Santo Domingo, El Pulpito and lastly

The deepest working of this mine is only 750 feet.

Adjoining the Promontorio on the north is the Quintera mine which has been frequently described. A view of the smelter and the mine are shown in the accompanying illustrations. The next mines of importance are the Santo Domingo with workings 400 ft. deep and El Pulpito, with an 800-ft. tunnel from which ore running as high as 5000 oz. in silver has been produced. The Zambona workings are 1050 ft. deep and it is supposed to have produced upward of \$10,000,000.

These properties are all situated on the east side of an intrusive porphyry dike at the contact with the granite. There are many old silver-lead mines on the west side of the mountain, among the most important of which are La Paloma and the

QUINTERA MINE AND SMELTER, ALAMOS DISTRICT

facilities would not more than compensate for the depreciation of the white metal since these old silver producers were active.

Twenty-six years ago Alamos was 300 miles from a railroad. Two years ago it was 200 miles away with a wagon trail. Up to eight months ago it had an Indian problem—the serious one of the Yaquis. Last year President Diaz called into council the chief of the Yaquis and certain other State officials and in his summary war practically settled the Yaqui question. The district has today a railroad penetrating the heart of the country—Harriman's Cananea, Rio Yaqui & Pacific—putting it in rail touch with the smelting and supply centers of Arizona and Texas, and water communication with San Francisco and supply centers of the west coast.

DIVISIONS OF THE ALAMOS DISTRICT

The mineral district of Alamos may be

*Civil and mining engineer, Alamos, Sonora, Mexico.

the Zambona. The Teresa, a promising prospect, is the north extension of the Zambona.

The Balvaneria has a well defined vein or ledge about 25 ft. wide apparently carrying commercial ore from wall to wall. A crosscut at the 225-ft. level, giving about 150 ft. of backs, shows an 8x8-ft. face carrying a good grade of copper ore with silver as high as 100 oz. and some gold. A crosscut below this which should give 700 ft. of backs is now in about 100 ft. There is no machinery at this mine and the ore taken out was treated at the Quintera plant.

Two miles north of the Balvaneria is the famous old Promontorio mine which was a continuous producer for over 150 years, with a mint record of 46,000,000 oz. of refined silver. Work was suspended on this property in 1895. The American company which bought the Mexican concern in 1905 is now installing a \$100,000 plant.

San Jose which are about one mile west of Promontorio. From the description it will be seen that practically the whole top, both the east and west slopes, of the Alamos mountain is thoroughly mineralized.

PROPERTIES ON THE NO. 2 CONTACT

The No. 2 contact is also an intrusion of porphyry through granite with andesite, rhyolite, dolomite and other igneous rocks appearing at intervals the entire length, a distance of approximately 100 miles. It is about 20 miles east from contact No. 1 and extends from the Fuerte river—near Agua Caliente de Boca—through the foothills of the Sierra Madres, crossing the Mayo river at the Solitral ranch and the Yaqui at Los Hornos. For the entire length one will find hot springs recurring at intervals accompanied by indications of geyser action.

Beginning at the south, there are the following mines in the order named: Jacolitas, with a 20-stamp mill and cya-

nide plant now in process of construction, the Vaughn placer, El Cobre, Cobre Grande, Sabino Solo, Dulces Nombres and Cerro Colorado—all south of the Mayo river. Continuing north there are the gold diggings at Sobia, copper camps at Baucari and Mojari, near which are the mines of the Douglas Copper Company. Then come the gold mines at Quiriego, where there is a 50-ton cyanide plant, *antiguas* at Balamote, gold mines at La Dura and the Golfo Del Oro.

CONTACT No. 3

Approximately 20 miles east of the No. 2 contact is contact No. 3 which lies just below the crest of the western range of the Sierra Madres and extends the entire length of the Alamos district. It is hidden and broken here and there by overflows of lava and intersections of tufa ledges.

Mayo at San Bernardo and follows the general course of the river to the northeast is on low-grade copper ore for two days. Silver and lead ore are found in the San Jose and gold ore in the Yaqui Indian, the Duraznos, and the Jay-Bush Bonanza.

The Duraznos company is now putting in a 20-stamp mill on the Chihuahua side of the mountain and large operations will soon commence at the La Luz, the ore from which will be shipped to Swansca. Like every district having high-grade ore, there are several "lost mines" in this country, among which are the "Tayopa" and the "San Andreas del Oro."

Supplemented by the railroad, the natural facilities for economic mining in the Alamos district should cause a renewal of activities here. Wood and water are everywhere and water-power opportunities

to Minaca, and rails are being laid for 100 miles farther southwest. The connections will probably be made within a year, opening to the prospector and investor one of the most generally mineralized sections of the Republic.

The work of "Boss" Shepherd at Batopilas has often been described and is already familiar to the readers of the JOURNAL. The producers of Arteaga pass and present have a history of over 250 years. Among the prominent ones, are the Palmarejo, Guazapares, Millionaria, Montezuma, Zapote, Rincon la Republica and La Mejicana. In this district there are many mill sites where electrical power might be developed at all times of the year and there is abundant water for milling purposes in the dryest seasons.

About 22 years ago when the nearest railroad was 300 miles away, an English

ZAMBONA MINE AND REDUCTION WORKS, ALAMOS DISTRICT, SONORA, MEXICO

Veins are found on this contact embracing a wide variety of commercial metals. At Cerro de la Rosa on the south are outcrops of tin. A little farther north are a series of old mines where are over 100 "townies," or arrastres, and 5 adobe smelters. The western slope of the mountains for 50 miles is a continuous series of old workings with a network of veins as yet practically untouched.

The gold placers at Baboyahui are yielding the operators good returns. From this point north to Muerto on the San Rafael ranch is "tierra incognita," but from San Rafael north to Cienega, as far as I have followed the contact, the outcroppings are noteworthy. Near Cienega lies La Luz where outcrops of cobalt and nickel have attracted attention. There are numerous copper deposits, among which are the Don Juan and others. The mule trail that crosses the

are innumerable; for labor they have the Yaqui, the Mayos and the natives of Sinaloa. Between its mineralized mountains and within a radius of 75 miles, it has a soil which will grow bumper crops of almost any man or animal foodstuffs.

THE ARTEAGA DISTRICT, CHIHUAHUA

This district is situated on the east side of Duraznos and Santa Rosa mountains and is drained by the headwaters of the Chinipas, Fuerte, Choix and Setentrion rivers. It will be bisected by the "Stillwell" road, the Kansas City, Mexico & Orient, which lacks about 125 miles of completion through this section. The road is now operated from Topolobampo on the gulf coast northeast to Fuerte, and track is laid to a point near Choix, Sinaloa, near the three corners of Sonora, Chihuahua and Sinaloa. On the east the road is being operated from the city of Chihuahua

syndicate came to the Arteaga country, a narrow-gauge railroad with accessory equipment was packed by mountain trail and wagon road to the Chinipas river and a railroad was constructed from the river to their mines 16 miles back in the mountains at Palmarejo. The power line was run along the river for a distance of 20 miles to furnish the power for the mills. Large dividends were paid and the plant extended from time to time, so that it is today the largest operation in this section. Among the other active properties in the district is the White Chief, which is operating a 15-stamp mill and is to add 20 stamps this year; the Duraznos and Guazapares are each putting in new mills, and it is expected that operations will be resumed in the near future at La Mejicana, and at La Republica. When the Stilwell road becomes operative this will doubtless be a busy district.

The Cananea Consolidated Copper Co. in 1908

Ores and Concentrates Treated and Fine Copper Produced Showed Slight Decrease as Compared with 1907; Cost of Mining \$2.13 per Ton

B Y L. D. R I C K E T T S *

The following report of operations of the Cananea Consolidated Copper Company covers the calendar and fiscal year 1908. The figures of production are for the period beginning July 11, 1908, when operations were resumed, to the close of the calendar year:

ORE TREATED AND METAL PRODUCED.

	Tons Wet.
Domestic ore treated.....	293,554
Custom ore treated.....	72,088
Total.....	367,642
Ratio of concentration, domestic ore milled.....	3 12 tons into 1
Ratio of concentration, custom ore milled.....	4.02 tons into 1
	Pounds.
Returnable fine copper in domestic bullion.....	15,679,685
Returnable fine copper in bullion from custom ore.....	2,939,924
Total fine copper.....	18,619,609
	Ounces.
Silver in domestic bullion.....	272,651.24
Silver in bullion from custom ore.....	175,011.99
Total silver.....	447,663.23
Gold in domestic bullion.....	1700.683
Gold in bullion from custom ore.....	1178.150
Total gold.....	2878.833

Recovery from domestic ore and other material treated was as follows: Copper, 2.652 per cent.; silver, 0.923 oz.; gold, 0.00575 oz. The value of precious metals per ton of domestic copper produced amounted to \$21.09.

The following development work was done during 1908: Shafts, 412.5 ft.; winzes and raises, 3550.5 ft.; tunnels, drifts and crosscuts, 9388 ft.; total, 13351 feet.

THE MINES

The following statement covers the tonnage and costs of mining at the various mines:

	Wet Tons.	Total Cost.	Cost per Wet Ton.
Puertocitos.....	18,465	\$41,550	\$2.250
Elisa.....	40,581	71,580	1.764
Capote.....	15,923	82,089	5.155
Oversight.....	142,825	272,767	1.910
Veta Grande.....	91,901	191,992	2.089
Total.....	309,696	\$639,997	\$2.131

Puertocitos—No underground work is being done at the present time. The mining at Puertocitos is entirely quarry work, and is done without the use of machines. The face of the mountain is broken down and broken up by hand, and about 30 per cent. of the total rock broken is sent to the smelter and 70 per cent. of practically

barren rock is thrown over the dump. The output of this mine has been a little over 3000 tons per month, and has averaged 3.16 per cent. copper, 3.86 oz. silver, and 0.028 oz. gold. It is a nearly neutral ore. We expect to increase the tonnage during the coming year.

Elisa—Owing to the very desirable nature of the Elisa ore and the greatly decreased costs of mining and smelting, we have lowered the grade of ore from this mine and largely increased the tonnage. We are working not only in the lower levels, but also in a quarry and in the old levels and are finding much old filling that is profitable, and a large amount of good ore in place in the old stopes. Upon the whole, the development as far as it has gone at Elisa has been satisfactory and there is every promise of an equal or increased tonnage from this mine. The steam plant has been entirely abandoned and the power is furnished by electric current from our smelter power house.

Capote—During the shut-down an effort was made to put out the fire which has been burning here for several years. We succeeded in putting out most of the fire by filling the mine up to nearly the third level. On allowing the water to subside and starting to reopen the mine, however, we found one small area of fire above the third level which got the better of us and drove us out of the mine for a time. The gases were finally controlled and turned out through No. 9 shaft. It was then found that the old workings were badly settled and new extraction drifts had to be opened in many instances; it was four months before the mine could be got into shape for production. Almost the entire output was made in the last two months of the year, but the cost of mining includes the large amount of dead work we were obliged to do during the four months that the mine did not produce. For the month of December the mining cost was \$2.11 per ton. We find that a very large portion of the old filling is profitable, and this is being drawn between the third and second levels. We are also finding large bodies of ore in place which we are working profitably.

Oversight—We have spent a great deal of money in opening up the old upper workings, which had not been worked for the past five years. This portion of the mine has made very little production on account of the difficulty in getting an outlet, but a satisfactory showing has been made in the way of blocking out ore, and in the coming year these old workings will

produce a notable output, chiefly of smelting ore. Connections have been made with the main Oversight workings and thence directly by inclined winze to Veta No. 9 tunnel. Through the workings of the mine the grade of the ore has been satisfactory, and we have in the proven ground opened up fully as much ore as we have extracted. We have also opened up new ore in no great quantity but of very satisfactory grade between the third and second levels in the southeasterly workings in block 17.

Veta No. 9 tunnel has been driven ahead several hundred feet and has run into mineralized ground, and connections have been made from near the face of the tunnel with the old workings of the Oversight, as mentioned. We have also found on the Veta No. 9 level a body of ore averaging about 5 ft. in width, which goes direct to the smelting works.

Veta Grande—The Veta Grande is maintaining its normal output of ore both in tonnage and grade. The ore is so silicious that almost all of it goes to the concentrator, but blocks along the footwall are sent to the smelter. This ore is the best concentrating ore that we have at the present time, having a high ratio of concentration and making the highest grade concentrates. We have made extensive developments on the third, fifth and sixth levels. So far the developments on the sixth level have cut no ore. The work on the third and fifth levels has not yet progressed far enough to determine the value of the ground we are prospecting.

Kirk Workings—Nothing was done until the very end of the year, but this mine is now being opened up; shipments were resumed in January, 1909. It is proposed to do a great deal of development work in this locality during the coming year and we expect that the ore already opened will more than pay for this extensive work.

DEVELOPMENT WORK

Our policy has been to be exceedingly severe in charging the mines with every expense attributable to them, and the mining costs include every expense incurred by the mines, even construction work as well, of course, as development and extraction. For this reason and from the fact that the reopening of the mines required a great deal of attention from the foremen, we did not do a great deal of development work during the first few

*General manager, the Cananea Consolidated Copper Company, Cananea, Mexico.

NOTE—Abstract from report of the Greene Consolidated Copper Company for the year ending Dec. 31, 1908.

months, but this work has been notably increased and during the coming year we expect to develop very extensively. This work will be carried on not only within the known limits of orebodies, but we also propose to develop extensively in our great outlying territory which has hitherto received little attention.

During the year S. F. Emmons, of the U. S. Geological Survey, assisted by J. M. Boutwell, L. C. Graton, W. H. Emmons, and other engineers, completed a valuable geological survey of the camp and gave us many valuable data which we will use in future development in new territory.

During the year we attacked four new outcrops that we deemed promising. The first of these is at Pavo Real, about one mile northwest of Elisa. Exposed on the surface are blowouts of copper-stained rock with bunches of high-grade ore scattered through it that contains a trifle over an ounce of silver to 20 lb. of copper. We have started a crosscut tunnel to strike under this outcrop 260 ft. below the surface, and have run about 200 ft. out of a total of 460 ft. necessary to get underneath the outcrop. At the same time we are running an adit tunnel from the Henrietta mine to prospect the ground between the Henrietta and the Pavo Real. In case this very promising territory develops the latter tunnel will come into Pavo Real 160 ft. below the Pavo Real tunnel.

We have on the southeast end of the Capote and the northwest end of the Oversight, as far as developed, highly altered mineral-bearing porphyry that is too lean to work, and we are now prosecuting development work to test the large area of undeveloped territory between these two mines. It also seems probable that the main fault of the Capote passes back of the Oversight, and we are running a number of crosscuts from the Capote and Oversight workings to the southwest to test this ground. Six of these crosscuts have been started on various levels, and the distance horizontally between the farthest of these is about 2000 ft. It is our purpose to carry some of these crosscuts nearly through the mountain for, aside from the possibility of the Capote zone extending back of the Oversight, we know that beyond the hard core of the mountain there is an immense area of soft mineralized porphyry, and it will be necessary to prospect the contact between these two classes of rock.

Mr. Kirk has started an adit tunnel called Veta 15, under a very large virgin outcrop lying southeast of Democrata gulch and about 1000 ft. southwest of the Kirk workings, and ultimately it will form a part of the Kirk mine. At the same time he is driving to develop the same large territory on the third and fifth levels of Veta No. 5 shaft. It is too early yet to make statements regarding this ground further than that we have reason to be-

lieve that it is exceedingly promising.

About two miles to the southeast of the Oversight there is a promising cropping on which we have been doing some tunnel work for some time. Altogether we have done over 1000 ft. of work at a nominal cost, and have found porphyry highly mineralized and similar in its nature to the ore-bearing porphyry of the camp. We have struck nothing of commercial value as the copper contents are far too low to be considered as even possible commercial ore. The prospect, however, is a promising one and deserves very much more work.

Mr. Emmons thinks the territory beyond the Elisa mine promising, as we all do. Furthermore, the deeper workings of the Elisa are now 200 ft. below the lowest adit tunnel. We have started the "combination tunnel" on the level of the Capote ore bins which will pass for 3000 ft. through the property of the Indiana-Sonora Copper and Mining Company, and thence through the Elisa mine, tapping the ore 40 ft. below the deepest level. This will give a new and cheaper outlet to the Elisa, drain the mine, and ultimately will extend back to prospect the ground beyond. While we drive this tunnel the Indiana-Sonora company pays one-half of the total cost for the 3000 ft. through its ground.

THE COST OF MINING

The cost of mining for the total tonnage mined was \$2.13 per wet ton. For the 15 months ending Oct. 31, 1907, it was \$3.28, and for the year 1905-1906 it was \$3.85. Great credit belongs to the mining department for this showing under most difficult conditions. The reasons for the decreased costs are twofold. First, the slicing and caving system has been thoroughly learned and applied to the various mines in the modified forms which the conditions demand. This has resulted in a decreased amount of timber and supplies and an increased efficiency of the men. The second reason is that the mining department has been entirely reorganized, and the average pay per employee has been decreased by this readjustment very nearly 20 per cent. We have, therefore, a decreased cost per man and an increased output per man. For the period in question the output per man has been increased from 1.2 to 1.6 tons, and this covers not only the miners but the muckers, trammers, blacksmiths, and in fact every employee of the mines up to and including the foremen. It is hard to realize the difficulties that have been encountered in accomplishing this, but it had to be done and was done.

Departing from facts and predicting for the future, I have little doubt that we will be able to maintain and improve upon these costs in spite of the tremendously increased amount of development work

we propose to do and we can look to continued decreases in mining costs rather than increases for some time to come, but in saying this I am keeping in mind certain capital expenditures which are exceedingly urgent. This construction provides cheaper compressed air and more electrical power at the mines. You have authorized and we are now installing an air compressor of 6000 cu.ft. of free air per minute capacity at the power house, and will lay a pipe line to four of the mines and replace with this one machine eight uneconomical small machines. Since the reverberatory furnace is generating an average of over 600 h.p. we have a surplus of boilers at the power house and no new boilers are needed, and our power-house condenser is abundantly large to take care of this compressor. In addition to this we are now up to the limit of our electrical-generating capacity and it is essential that we should put in more power for the use of the mines. John Langton, consulting engineer, is now making a study and report on our power equipment and is preparing specifications to be submitted to you. It would appear that with an expenditure of \$57,000 we can increase our capacity 1000 kw. and reduce the cost of generating power per kw.-year about 15 per cent. If this unit is put in there is no question but that other capital expenditures will be required because if we can change over our steam hoists at four of our shafts to electrically driven hoists by the addition of the proper motors we can abandon entirely four very expensive steam plants. If the program is approved and carried out it will require a total expenditure of about \$120,000. In making this recommendation I have carefully considered the tremendous expenditures that we have had to make and am still keeping in mind the rule of recommending only expenditures that will pay for themselves in one year's operations.

THE CONCENTRATORS

During the close-down a new and more powerful engine was installed in the old mill and the final addition to the vanner room of the second section was completed. Two new Chilean mills, designed by Mr. Cole, were added to the fine crushing department, and the worn-out rolls were replaced by Mr. Cole's improved rolls which he manufactured here. The timbers of the old mill resting on the masonry foundations had largely rotted out and extensive improvements were made by replacing these timbers and rebuilding the floors.

Since the close-down we have done no pumping from Capote and the pumping operations at the Indiana-Sonora mines have been discontinued. The removal of these two main sources of water from the concentrator was most serious and arrangements had to be made to meet the conditions. We consequently laid a

wooden pipe line from the Cananea Duluth via the America, and pumped the water directly from these mines to the Cobre Grande tanks whence it flows by gravity to the concentrator. This line is made up of 3935 ft. of 8-in. and 2800 ft. of 12-in. pipe. We have also developed water in the main arroyo 12,000 ft. below the concentrator and have here installed an electric pump and laid a pipe line partly of 6-in. steel pipe and partly of 8-in. wood pipe, to the tanks at the head of the concentrator. This line now delivers about 250 gal. of water per min. at a cost of about 6c. per 1000. We have also developed all the water possible in Puertocitos creek by a bedrock cut 300 ft. long and a bedrock tunnel 400 ft. long, and have installed a steel flume 5285 ft. in length to bring the water over the divide. An 8-in. wood-pipe line 12,000 ft. long will be laid from the latter flume, leading the water by gravity to the sump tanks at the foot of the concentrator. This pipe line will be completed early in March.

We have also laid an oil line from the main storage tanks to the power-house boilers and installed storage tanks across the cañon from the mills to store fuel oil and from which the amount of fuel oil consumed under the boilers is measured. The cost of all of this work has been charged currently to operations and has tended to make the cost of concentration exceedingly high.

The crusher plant was provided with a condenser and cooling system, part of which installation was made in 1907. During the past year we have designed and ordered the necessary material for a condensing system for the steam plants of both mills, and this will be installed during the coming year.

Recent practice in the southwest has shown that direct-acting pumps are far more economical than centrifugal pumps for lifting the water, and our power costs have become so high for re-pumping that the matter has become acute. We have ordered eight Aldrich triplex-plunger pumps to replace the centrifugal pumps now in use. Some of the foundations were put in toward the end of the year and we expect to have all of these pumps running in a few months.

The Cananea ore is probably the most difficult to concentrate of any copper ore in the country on account of the tremendous amount of clay, which is not only not susceptible to dressing but prevents proper settling of the fine sands. Our losses on this account are high and there are certain losses that we have proved by experiment, we can recover by collecting the fine sands from the large settling tanks below the mill and reconcentrating them. We are now installing a vanner house about 300 ft. in length on the opposite side of the cañon, and will re-handle the fine sands from the tailings over the 40 vanners and to Card tables that are being installed therein. In con-

junction with this vanner house Mr. Cole has installed settling tanks of approved plan, and it includes, of course, appliances for conveying the concentrates to the railroad storage bins. Later on we propose to double the capacity of this plant. The preliminary installation will cost \$50,000 and the additional 50 vanners will cost about \$30,000 more. In all of these improvements we have followed the plan of undertaking no construction that will not pay for itself within a year.

The cost of concentration of the domestic ores was \$0.94 per ton on account of the immense amount of construction charged to operations but the result will be not only an increased saving, which is badly needed, our present saving being only about 70 per cent., but we can safely see a reduction in cost to 75c. per ton or under. The same care was taken in re-organization in starting up the concentrator with what undoubtedly is very beneficial results.

As is customary with most milling plants in the United States, in past years the tailings have been largely thrown away in the gulches and carried away by floods. I have decided that in the future we will permit no more tailings to go down the gulch, and at present we are building a dam which will ultimately be about 50 ft. in height and which will store nearly 2,000,000 tons.

THE REDUCTION DIVISION

Space will not permit a full description of the work done in reconstructing in this department.

Receiving, Bedding and Reclaiming—This splendid invention was in the main installed under the management of Arthur S. Dwight, and was designed and constructed under his direction with the assistance of E. H. Messiter, consulting engineer for the Robins Conveying Belt Company. The departure was an entirely new one and difficulties were found in operation. The conception of the bedding system is one of the most brilliant of which I know and the vital portion of the construction has worked to perfection. The receiving end, however, was too limited, and such difficulties were encountered with the proposed feeding device that it had to be abandoned after fair trial. During the close-down additional bins of 3000 tons capacity, with an automatic feeding device, were added to the receiving end, the sampling works were overhauled, and the crushing machinery changed, and an entirely new device for receiving the mixture above the furnaces, and feeding the furnaces was installed. With these changes this system has worked with great economy and most satisfactory results.

Smelting and Converting Departments—These two departments embracing the smelter proper are virtually new; in other words, a new smelter has been built on the old site and nothing remains but a portion

of the steel structural work of the main building, which has been reinforced, and the converter runway and cranes, which have been rebuilt. All of the furnaces are new, the feeding device and feed floor are new, the five stands of converters and twenty shells are new, as are also the slag tracks, slag pots, bullion tracks, bullion dock, pumping plant, and so on through the list. In making these changes most careful attention has been paid not only to improved facilities for handling materials but for the comfort, facility and safety of the workmen, and a great amount of excavation work has been done and a great amount of material has been torn out, giving splendid air and light both for the feed floor and the tapping floor and converter bay.

McDougall and Reverberatory Furnaces—The McDougall roasters that were partially installed under the management of Mr. Dwight have been completed and run at sufficient capacity to supply enough calcines to add to the flue dust treated to bring the reverberatory up to its full capacity.

The reverberatory furnace was entirely rebuilt after obtaining fuel oil for smelting. The results obtained have been most satisfactory although we have still much to learn regarding reverberatory practice. The results have constantly improved since starting up and will continue to improve. The waste gases give 50 per cent. as much steam as all the oil would give if burned under boilers.

Power House—The boilers at the power house have been equipped with oil-burning apparatus. One man on a shift attends to the boilers in place of the 18 once employed. In the power house proper a new No. 10 rotary blower with direct-connected tandem-compound engine has been installed. The foundations of all the converter blowing engines have been rebuilt. All of the machines have been thoroughly repaired, and a condensing plant installed that is very satisfactory.

I have made the description of the changes in the reduction division brief in spite of the great sum of money we have spent in reconstruction for the reason that I think a statement of the results will be sufficient. We are running at the present time six furnaces and smelting about the same tonnage we were formerly able to smelt with eight, with two furnaces to spare.

The average daily pay-roll at the smelter, including the power house, was formerly \$1823, and during the past six months it has been \$763. The efficiency of blast in converting has been raised from 43 to 67 per cent., and the efficiency of blast on the furnace has been raised a corresponding amount.

The reverberatory ran 150 furnace days. It treated 30,275 tons of net dry charge at a cost of \$1.83 per ton, allowing a credit of 60c. per ton for steam generated

in the reverberatory boilers. This average is high because the first few months' run was very much more costly than later on and we have recently been smelting for about \$1.37 per ton, allowing credit for steam generated. The cost of power has been reduced about 40 per cent.

The accompanying table, compiled from Mr. Shelby's report, shows comparative results for the six months prior to and the six months subsequent to the shut-down, covering the total reduction division costs per ton of ore and old secondaries treated, per ton of new material treated, and per ton of fine copper produced.

COMPARISON OF PRODUCTION AND COSTS.

(BASIS PER DRY TON).

	Tons Treated or Produced.		Total Costs.	
	1907.	1908.	1907.	1908.
Ores and concentrates...	220,446	164,361	\$6.82	\$3.86
Net new material...	299,620	217,177	5.02	2.93
Fine copper...	11,103.288	9,295.769	135.47	68.47

THE RAILWAY DEPARTMENT

The railway belonging to the company has been maintained at its usual standard of excellence. It is in splendid condition both as to road bed and equipment, and for a long time to come I can see no important repairs with the exception of a few bridges between Henrietta and Puertocitos. The total mileage, including main lines, spurs and sidings, and including standard, 3-rail, and 36-in. gage tracks, amounts to 51.92 km., or a little under 32 miles.

The operating service of the narrow gage has been reorganized and in spite of the average lesser tonnage for the six months of operation, the total cost of operating has been reduced 25 per cent., and the average cost of hauling all ore has been reduced from 11.9c. to 7.26c. per ton. We are now equipping some of our engines with oil tanks and burners and find a notable increase in haulage capacity and a notable decrease in fuel costs. The equipment is largely new, ample and all in excellent repair and will last for many years.

FUEL OIL

Upon receiving the concession to import crude oil for fuel purposes it was necessary to provide storage tanks. A site was selected at which the oil could be discharged from the railway cars by gravity into storage tanks and from which the oil could be piped by gravity to the subsidiary storage tanks at smelter and concentrator, where the tanks could be placed a sufficient distance apart to insure safety to the others if one caught fire, and where if a tank exploded the burning oil could escape without doing serious damage. Three 10,000-bbl.-capacity tanks were manufactured at Cananea and erected, the necessary piping was completed and oil was got to the reverberatory furnace and to the

power house in August. Since then the line has been extended from the concentrator to Veta No. 9 and Capote, and provision made for hauling oil in tank wagons to Ojo de Agua, and storage tanks have been installed at these three localities having an aggregate capacity of over 6000 bbl. At each of the main plants there have been provided two small tanks by means of which we can accurately measure the amount of oil consumed on each shift. The cost of the three large tanks and the pipe lines to the smelter and concentrator were charged to construction, but the other pipe lines and installation were charged to operating expense. A contract was let with the Texas company for fuel oil covering our entire needs for two years up to 35,000 bbl. per month, which is more than sufficient for our consumption during the next two years. We find 3 bbl. of this oil equivalent to one ton of run-of-mine coal, and the saving in labor is notable.

MINING AND BENEFICIATING

Copper costs for six months of operation were as follows:

Gross costs, f.o.b. Cananea	\$0.0992751
Freight to New York, export tax, re-fining, marketing, interest, etc.	0.0168642
Total cost	\$0.1161393
Credit for value of precious metals	\$0.0105446
Miscellaneous revenues at Cananea	0.0075206
	0.0180652
Total cost of fine copper sold	0.0980741
Construction not charged to operation	0.0070583
Cost including every expenditure	\$0.1051324

The yield of copper per ton of ore benefited given at the beginning of this report is misleading in that during July we smelted a considerable tonnage of cleanings found in tearing out old ore bins and other structures. The actual net yield of the ore benefited was 51.25 lb. per ton as against 46.58 lb. for the 15 months ending Oct. 31, 1907. Owing to the decreased cost of smelting we have been able to send leaner ores of the Puertocitos and Elisa class to the smelter with a handsome margin of profit, and we have been able to smelt leaner ores that formerly went to the concentrator. This has resulted in increasing by nearly 50 per cent. the percentage of direct smelting ore to the total ore mined and has caused an increased yield per ton. As a matter of fact, therefore, the average gross copper contents of the ore have not increased even as much as the figures above would indicate. On the other hand, the greater percentage of ore smelted direct has tended to increase the total cost of mining and beneficiating a ton of ore, but with this increase the cost is more than paid for by the increased saving of values.

The following is the total cost of mining and beneficiating a ton of ore, including every cost until the refined products are sold.

Period.	Cost Per Ton.	Tons Beneficiated.
Fiscal year 1905-1906	\$10.21	947,977
Aug. 1, 1906, to Oct. 31, 1907	7.625	1,395,291
July 11 to Dec. 31, 1908	5.976	295,554

The results show a decreased cost during the six months of 1908 of \$1.649 per ton over the previous period, and a decrease of \$4.234 over the fiscal year 1905-1906. In other words, had we been able to mine and beneficiate the ore for the 15 months ending Oct. 31, 1907, under present conditions the cost would have been decreased by about \$2,150,000 plus the value of the increased saving.

In making a careful and balanced study of the cost of mining and beneficiating ore two years ago the vital features were obvious. It was necessary to get cheaper mining costs, cheaper smelting costs, cheaper fuel, cheaper power and cheaper transportation. While we have made notable advance on the first four items we have been unable to obtain any adequate concessions in the matter of the heavy freight rates on fuel and supplies. We are virtually in the same location as our neighbors across the line when the great distance from the source of fuel, coke and supplies is considered, yet we are charged rates that in the aggregate amount to 1c. per lb. of copper in excess of the rates paid by our neighbors, and the burden is hard to carry. The question is serious, yet we think fair freight rates would mean increased tonnages that give the highest profit to all concerned.

While predictions are dangerous, and I have in this report only given figures from results actually accomplished, I have no hesitation in saying that we shall be able to continue decreasing the cost of mining and beneficiation and increasing the percentage of saving to a notable degree, although we cannot expect to make reductions corresponding to those made during the past year.

It should be remembered that we have been handling a decreased tonnage and it is true that an increased tonnage will undoubtedly lower the cost of beneficiation.

SELF-SUSTAINING DEPARTMENTS

The mercantile department received a hard blow on account of the close-down for the reason that it had large stocks, some of which was perishable; furthermore, the business was not well organized. The combined result has been that including losses from depreciation of stock and expenses of reorganization and construction, it has made a loss for the past year. During the fiscal year George Young, in addition to the other capacities in which he serves, assumed the management of the mercantile department. He has completely reorganized the department, and at the present time it is making a profit, and it is in healthy and good condition.

The sales from the lumber yard, including lumber, wood, coal, hay and grain, etc., have been satisfactory considering the dull

times, and this department is ably managed.

John A. Campbell, who took charge of the public service department in addition to his other duties, before the beginning of the fiscal year, has met with notable success, and the profits promise to pay in the future a fair rate of interest on the capital invested.

On the whole, all of the self-sustaining departments are now healthy and bid strong to show better results.

FEDERAL AND STATE CONCESSIONS

During the year we have received a valuable concession from the Federal government. There is a prohibitive duty against crude oil into Mexico for the purpose of protecting the refining industry, and consequently the Cananea Consolidated Copper Company was obliged to use high-priced coal. Upon bringing the matter to the attention of the Federal government they granted us the privilege of importing crude oil exclusively for fuel purposes into Cananea, under inspection, as long as the government believes that the native product cannot be furnished to us under competitive conditions.

In consideration of the improvements we have made at the reduction works and of the installation of additional power, the State government has canceled our original concession for 20 years dating from Dec. 4, 1899, and given us a new concession for a period of 20 years from April last, exempting us from the payment of export tax on copper bullion produced from our mines. We are under very great obligations both to the Federal and State governments for the just and considerate treatment and assistance they have given us.

IN CONCLUSION

The staff of the Cananea Consolidated Copper Company, with some reductions, remains as it was when I took charge, and I feel that we are under great obligations to its members for the splendid courage and ability they have shown and the splendid work they have done. All the work accomplished has been the result of friendly and earnest committee work, and all steps made have been taken after the most thorough discussion and study.

Local conditions have been exceedingly satisfactory throughout the period. We have an excellent and capable municipal government and a contented community, and as far as I can see, there is no discontent or friction between the company and its employees. The latter have rendered good service and good work.

It is reported (*Mex. Min. Journ.*, Feb., 1909) that a rich discovery of gold-bearing quartz has been made on the headwaters of the Andagueda and Chiriquí rivers, 125 miles above Quibdo, Colombia.

Electrolytic Precipitation

By MARK R. LAMB

This method of recovering metals from cyanide solutions was proposed early in the history of gold cyaniding in Africa. Solutions from ores containing $\frac{1}{2}$ oz. gold per ton will contain about $2\frac{1}{2}$ dwt. per ton where four tons of solution are treated for every ton of ore crushed. This ratio of solution to ore is not an average, since Merrill precipitates from only 0.6 tons of solution per ton of slime treated, while at places in Nevada with very high-grade ores the ratio is eight to one. Taking the ratio of four to one as a basis for calculation, the lowest-grade solution may carry 0.25 dwt. per ton, and the precipitation from this grade is quite as important as the treatment of the higher grade solutions.

Recently Mr. Lay has given results of his tests and daily working results on precipitation, and places the ratio for practically complete precipitation of clear, gold solutions at 0.03 amp. per sq.ft. of cathode surface. The quantity of metal in such solutions is so small that the area of the cathode is by far the most important factor of the precipitation. He estimates the required cathode area as 1750 sq.ft. per ton of solution per hour, and is using thin, lead-foil cathodes which remain in the boxes a month before being melted and cupelled.

The usual ratio of solution to ore in silver cyaniding is from four to six tons solution to a ton of ore. Then with an ore worth \$6 per ton, such solutions would contain about $2\frac{1}{2}$ oz. per ton, or 40 times the weight of metal in gold solutions of the same value. It will be seen at once that the problem of electrolytic precipitation in dealing with solutions from ores containing from 500 to 1000 grams of silver per ton is much easier to solve, and is altogether different. By comparison the solutions dealt with in this last case resemble the electroplater's bath.

The managers and foremen of the plants operated by Charles Butters & Co., Ltd., have improved on electrolytic precipitation until they are now getting good results. Their object has always been to secure as complete a precipitation as is consistent with reasonable first cost and maintenance expense. Ordinary tinned iron plates are used as cathodes and peroxidized lead plates as anodes. Acheson graphite will probably replace lead anodes finally, since the latter are expensive and short-lived. A current density of 0.50 amp. is employed, which is 16 times the density recommended by Mr. Lay. This heavy current deposits the metal loosely on the cathodes whence it is rubbed, and dropped to the bottom of the boxes.

The variable conditions of the boxes used by Mr. Hamilton at Minas Prietas in making his tests were: current density, rate of flow of solution, besides the con-

stant slight fluctuations of alkali, cyanide and metal contents of the solution. The number of and distance separating the anodes remained constant. The accompanying table shows the conditions and results of the experiments made with solutions carrying 1.625 oz. gold and sil-

ELECTROLYTIC PRECIPITATION AT MINAS PRIETAS.

Tons Sol. Passed Through Boxes Per 24 Hrs.	Cathode Area of Box, Sq. Ft.	Current Density, Amp.	Percentage Precipitated.
120	3500	0.3	90.0
240	3500	0.7	84.0
120	3500	0.8	88.0
240	3500	0.8	84.5

ver. With solutions containing more metal, the box will have greater capacity for the same per cent. precipitation. Experiments prove that with constant rate of flow of solution and current, the residue remains nearly the same, with varying grades of solution. Doubling cathode area increases percentage of precipitation more than does doubling current strength, but it also doubles attendance and first cost of plant.

My object in writing this is to urge that a judicious combination of electrolytic and zinc precipitation will have an advantage over either alone. At one plant with which I am familiar, 80 tons of 50-oz. silver ore will be treated daily, producing approximately 4000 oz. of metal. At the lowest figure for zinc consumption this would require 270 lb. of zinc shavings per day. With an electrolytic plant precipitating 85 per cent. of the metal the zinc consumption will be reduced to 40 lb. with a very slight charge for power. In any case, the power cost is low. In this particular plant the labor required will be that of one man having extra help only at clean-up, who will attend to precipitation during the month. Then, too, in a closed-circuit plant, that is, one milling in solution and filtering, perfect precipitation is not required, since no loss is sustained if solution which is pumped to the battery supply contains more or less metal. Also in this class of plants the tonnage of solution to be precipitated is less, particularly where the entire tonnage is agitated.

The advantage of purifying the solutions which become so foul in treating the average silver-sulphide ore, warrants the use of a high-duty electrolytic-precipitation plant. Further, a recovery or regeneration of as much as $\frac{1}{2}$ lb. of cyanide per ton of ore treated has been observed. The product of the electrolytic boxes, when compared to zinc precipitate, is of lower grade if copper or other base metal is in solution and is of higher grade with clean ores and rich solutions. Such zinc as remains in solution after passing through the batteries, concentrators, and treatment plant is found in the electrolytic precipitate, but is of negligible quantity.

Traveling in Western Chihuahua, Mexico

Notes of a Trip to the Ocampo District, and Outfitting Therefor.
Time Required for Securing Superior Mules Is Well Spent

BY FREDERICK H. MORLEY *

Journeys in western Chihuahua are usually made over well traveled trails on mule back and the notes given here may be of some interest and benefit to engineers going to Ocampo, Portrero or Sahuayan. The Ocampo district is reached by trail from Miñaca or San Isidro on the Chihuahua & Pacific railroad, or by wagon road from Temosachic, the terminus of that railroad.

The wagon road was one of Colonel Greene's projects to supply transportation

ences before they learn that the crude native methods are often the cheapest.

MOST MAPS INACCURATE

The accompanying map and profile of the trail will give a general idea of the altitudes, distances and the names of the usual stopping places between San Isidro and Sahuayan, going by way of Ocampo. There are no accurate maps of this region, and no two maps agree within two miles. The sketch given here was taken from a

location of the difficult portions of the trail. Whenever possible two readings were taken at the same point, and the mean reading was used in plotting the profile, but in most cases it was only possible to get one reading, so that the altitudes given may be inaccurate by 200 ft. or more. A Keuffel & Esser 5-in. dial surveying aneroid was used.

COMMISSARY CONDITIONS

We started out from the Calera mine,

OCAMPO, ONE OF CHIHUAHUA'S INTERESTING TOWNS

CALERA MINE AND MILL

TOMÓCHIC RIVER

TOWN OF TOMÓCHIC, ALTITUDE 6000 FEET

facilities for his mining properties at Concheño, Pinos Altos and Ocampo. It was a well constructed road, over 100 miles in length, which must have cost a small fortune to build, but after a few months of neglect it is scarcely better than the trails. It is a well known fact in the district that freighting by wagons over this road cost many times what it did to pack out on mules over the trails to San Isidro or Miñaca. Americans in Mexico generally have some expensive experi-

ment before they learn that the crude native methods are often the cheapest.

"Riding time" is a very variable quantity, but under ordinary conditions means a rate of about $3\frac{1}{2}$ miles per hour. As we would always make much faster time on the level than when going up or down hill the profile is somewhat inaccurate and distorted, but it will serve to indicate the general character of the country and the

location of the difficult portions of the trail. Whenever possible two readings were taken at the same point, and the mean reading was used in plotting the profile, but in most cases it was only possible to get one reading, so that the altitudes given may be inaccurate by 200 ft. or more. A Keuffel & Esser 5-in. dial surveying aneroid was used.

COMMISSARY CONDITIONS

We started out from the Calera mine,

going to San Isidro, and from there through Guerrero over the *camino real* which leads directly to Ocampo. This trail joins the one from Miñaca at La Junta, which is about nine hours' ride west of San Isidro. The Miñaca trail is said to be the better. There are numerous stopping places all along the trail, but these usually consist of poor little ranches where one can secure fodder and a corral for the animals, though meals and lodging for the travelers may be entirely lacking. Some of the houses have an extra room for travelers, but as a rule we found it

*Mining engineer, 412 Mel'hee building, Denver, Colo.

more comfortable to sleep out under the portales or beside the corral.

At the time of this trip (December, 1908) it was rather difficult to buy food along the trail, although we could generally count upon a limited supply of *torillas* at exorbitant prices. At times we were able to buy a few eggs or a chicken, so that we were able to get along quite comfortably. If the traveler will take with him plenty of good, American bacon,

riding it should be possible to reach Ocampo in three days from San Isidro or Miñaca, stopping at La Junta and Tabacote; or at Tomóchic and Durazno. As we were poorly mounted and the days were very short it took us four days on the trail, though three and one-half days is said to be the usual time. The distance is generally given as 90 or 100 miles.

As a whole the trail is not a bad one, although there is scarcely any level

Ocampo is one of the most interesting towns in northern Mexico. It is said to be more than 100 years old, the first mine discovered being the San José in the year 1804. The only active and producing property seems to be that of the Watterson company, which is making a regular production and shipping bullion from its cyanide mill. Freight rates are so high that it is practically impossible to ship anything except bullion. The regular rate

SKETCH OF A PORTION OF WESTERN CHIHUAHUA

coffee, rice, and frijoles, he can travel light and live comfortably "on the country." It was always possible to buy sufficient corn and fodder for the mules, though prices were high.

SAN ISIDRO TO OCAMPO

Between San Isidro and Ocampo the usual stopping places for travelers are at Corralitos, Terrero, La Junta, Tomóchic, Tabacote, Durazno and Basasachic. Tomóchic and Basasachic are small villages, which have one store each, but the other places enumerated are merely *ranchitos*. With good animals and fast

ground, as the trail seems to cross a continuous series of hills and arroyos which makes very rapid traveling almost impossible. Between Basasachic and Ocampo there is a rapid rise, followed by a long, steep descent over a very bad trail. This part of the trail is extremely bad as it is not only steep, but also very rough and full of loose rocks. There are some rough stretches between Tabacote and Durazno, but as one gets farther into the heart of the Sierra Madre those portions of the first part of the trail which seemed steep and rough at the time are now recalled as smooth and level boulevards.

from Ocampo to San Isidro is 7.50 pesos per carga, and 5 pesos per ton from San Isidro to Chihuahua. The trip takes about 10 days, as the packers do not attempt to work their mules for more than four or five hours a day, during which time they make about 10 miles.

ROUGH TRAIL TO REFUGIO MINE

Going west from Ocampo toward Sahuayacan the trail is steep and rough until the Refugio mine is passed, there being a rise of about 1000 ft. in the first hour and a half of riding. Beyond the Refugio the trail is good and there are no

difficult places, as it follows along the *cumbre* for some 2½ hours.

After four hours' riding the ridge above Moris is reached. The view from that point is of surpassing grandeur. Immediately below is the valley of the Moris river and the little village of the same name, which is reached in three hours of sliding down a descent of 3300 ft. To the westward the two *pilares* stick up like giant obelisks, while range after range of rugged mountains extend indefinitely in every direction. We tried to get some photographs of this view, but they failed to give any idea of the grandeur and immensity of that vast sea of mountains. The trail down to the valley is frightfully steep and rather rough, but the mules can make it without difficulty if not too heavily loaded.

TROPICAL CLIMATE AT MORIS

At Moris we found a tropical climate, with sugar-cane, oranges, and bananas growing in abundance. The altitude of Moris is between 2300 and 2400 ft. Instead of stopping for the night at Moris we pushed on to Durazno—a fine little ranch where they raise sugar-cane and most delicious oranges. Three and one-half hours' riding from Durazno brought us to the Cienega mine, situated almost at the foot of El Pilar. There we found an interesting gold prospect which was being developed by the American owners. It was less than an hour's ride down the mountain side from La Cienega to Potrerito, while another half hour's ride down the river brings one to the village of Sahuayacan.

This district was very active at one time, but at present it is correspondingly quiet. The Santo Niño and Santa Teresa were the principal mines at Potrerito, but neither of these properties was being operated at the time of my visit.

As far as could be learned the Cienega, Socorro and Republica were about the only properties in this vicinity which were in operation, and I think that the Republica was the only mine which was then shipping out bullion. This is not surprising when we consider the location of these properties and look at the profile of the trail over which everything has to be carried.

Freight to the railroad is said to cost from 13 to 15 pesos per carga for ordinary loads, while the rates for machinery are very much higher. It is evident that only mines having high-grade ores which can be reduced to bullion can be expected to make very much money in such difficultly accessible localities.

POTRERITO TO CALERA

Returning from Potrerito to Calera we took the trail to Maicoba, going thence through Yepachic and Tutuaca to Tomóchic, where the regular Ocampo trail was again encountered. This route is probably much longer than that by way of Ocampo,

but as the trail is in excellent condition, and as there is very little rough country one can make somewhat better time over the Yapachic route. This is the trail generally used by the freighters going to La Republica, Sahuayacan and Socorro.

Between Yepachic and Tutuaca there is a stiff climb, and the ascent to the Mesa Correo is long and steep, but with these exceptions the trail is an excellent one for fast traveling. One must be sure to arrange to spend the night either at Tutuaca or Tomóchic, as there are no good camping places between those towns, while on the Mesa Correo there is neither feed nor water. Yepachic is the only town which boasts of a store until Tomóchic is reached, and as there are few ranches along the trail, one cannot count upon

days' riding, so that a day or so spent in insisting upon good animals and hunting for them may save many days later on.

We found that for two of us all of our requirements were met with an outfit of two saddle mules, one pack mule and one mozo on foot. The pack consisted of two canvas panniers containing the grub and cooking utensils, a bag of clothes, a mail sack containing the sampling kit, and the blankets wrapped in a heavy canvas tarpaulin. In addition we often had to carry corn enough for all of the animals for one day, but the pack was never unduly heavy. By traveling with a light pack and a small outfit much time was saved and a great deal of trouble and annoyance avoided.

In the rainy season it would be necessary to take a tent and folding cots, but these are not essential at other times. Such trips are never easy ones, but one is well repaid for a few hardships if he can have the opportunity to see and realize the rugged grandeur of the Sierra Madre.

Exploration Company, Ltd.

At the recent annual meeting of this company, it was stated that its investments in the shares of copper-mining companies stood at £199,877, distributed in shares of the Greene-Canea, Butte Coalition, Nevada Consolidated, Otavi Mining and Railway companies in Southwest Africa and some small holdings in a few other companies. The success of the investment in El Oro mines of Mexico has inspired the company to enter upon a systematic scheme of mining exploration in Mexico. For this purpose, it is intended to form a company with a capital of £250,000, the shares of which will be subscribed for by the Exploration Company. Philip L. Foster will be on the board of the new company and its general management in Mexico will be under the direction of R. M. Raymond, who for the last six years has managed the mines at El Oro with conspicuous success. Under him will be a staff of mining engineers who will be engaged in seeking for and making preliminary examinations upon mining properties in Mexico.

A working option for two and a half years upon a large mine has already been secured.

In Mexico (*Boletín de Estadística Fiscal*, Aug., 1908), during the fiscal year, 1907-8, titles for 91,307 pertenencias were granted to a total of 4841 persons or companies, making a total of 444,320 pertenencias held in the republic. Of these 180,850 are held for the mining of gold and silver, 105,424 for gold and silver with other minerals and 68,053 for other metals and minerals.

EL SALTO MILL—OCAMPO

obtaining many supplies along the road. We were out 4½ days from Potrerito to Calera, our riding time being 43½ hours, which is considered excellent time.

NOTES ON OUTFITTING

Traveling through this part of Chihuahua is not like riding in a Pullman, but the trips can be made very comfortably if one is accustomed to riding over mountain trails and knows how to "rough it." Most of the country is well supplied with water and wood, though nearly all grass along the trails has been cleaned off by the freight animals. Much time will be saved on the trail if care is taken in the selection of the mules available for the trip. Most of the animals usually furnished are wretched creatures which are likely to give out completely after three

Mr. Schwab on Steel Making

When Mr. Schwab testified before the Ways and Means Committee last December he was obviously uncertain of himself. He was in the position of many industrialists, who boast among themselves that in their lines of work America can beat the world in cost of production, superiority of manufactures, etc., and even exaggerate their optimism when it is a matter of floating a company, or otherwise selling a business; but are pessimists of the blackest dye when it is a question of protection against the "pauper labor" of Europe. Probably this is largely a matter of habit, or the exhibition of the business spirit which contests the relinquishment of any advantage. However, Mr. Schwab has now found himself, so to speak, and in a recent interview uttered brave and true words, as follows:

"Cut the tariff on steel or anything else all you please. American labor can stand it. I believe in a reduction. I feel just an Andrew Carnegie does on that matter. In my estimation American steel can stand all cuts in tariff that are made. American labor can make the best steel in the world, and with it we can compete with the world. I know nothing about other lines; that is, technically, but I have enough confidence in American labor to believe that cuts can be made in them without hurting business. I have been in contact with labor of all kinds for years, and I know what it can do. I know that American laborers can produce more steel in a given time than any other workmen in the world. I know that they can put out better steel than any others. We can compete with any other country. We have nothing to fear by a cut in tariff, because we have the best goods. It is true that we have to pay our workmen most; you always have to pay the most skillful workmen the highest wages. The Americans are the best workmen on earth. The highest paid labor is the cheapest to the employer. The man that understands his work thoroughly and executes it without mistakes is the man that makes money for his employer. The man that is employed at a cheap wage, and goes slowly and makes blunders, produces inferior steel or any other goods and cannot compete with the man that thoroughly understands his business and produces good material."

There is so much sound political economy in the above remarks that Mr.

Schwab is to be complimented for condensing a treatise upon a tablet. The timid demur and fear dreadful things that may happen to "Labor," but the captains of industry and the engineers who assist them know that the laborer is worthy of his hire, and that if the miner at Butte is paid \$3.50 for eight hours work, while the colored men in Africa may get only 50c. for 10 hours, nevertheless, the man at Butte will produce the cheapest ton of ore and is consequently the best money-maker.

Labor Efficiency and the Steel Corporation

It is well known that during the boom period of 1906-7 the cost of production of many substances increased materially owing to a large extent to decrease in the efficiency of labor. The opportunities for employment were so great that the laboring man could be independent. If he chose to relax his efforts, or be otherwise unruly, at the risk of being discharged, the chance of dismissal was entirely immaterial to him, knowing that he could immediately obtain employment elsewhere. Moreover, in many cases the most efficient men quit one kind of work in order to enter upon something else which paid better, thus illustrating the mobility of American labor. The managers of many enterprises were, therefore, obliged to content themselves, to a large extent, with an inferior class of workmen.

Since the panic conditions have been reversed. Since that time it has been jobs that have been scarce and labor that has been plentiful. This condition has enabled employers (1) to choose the best men, and (2) the men thus chosen have been inspired to work harder than formerly in order to retain their employment. The result has been a great increase in efficiency in many kinds of work and corresponding reduction in the cost of production.

However, this is by no means to be offered as a sweeping statement. There are many enterprises of long establishment and well settled character which employ the same men year in and year out with comparatively little change. Satisfied with their condition and untroubled by unionism, these men stick to their employment and bring up their families in homes around the works, in which the sons and grandsons eventually find employment. In works of that character there was prob-

ably no great decrease in efficiency in 1906-7, nor increase subsequently. Another important factor in the cost of production is the maintenance of operations at approximately the full scale. The laborer as a unit may increase in efficiency, and yet the cost of production may increase at the same time because the plant as a whole is not running at the maximum of economical capacity. The cost of some kinds of smelting, for example, will increase 5 to 10 per cent. because of the mere fact that the works is running at only three-fourths capacity.

Something of this kind appears to have been the experience of the Steel Corporation in 1908. Unfortunately its otherwise admirable report does not go into technical details. However, we can draw some general deductions. Owing to its much-discussed policy of maintaining prices, and allowing the comparatively small business offered to be taken by rival concerns, the production of the Steel Corporation showed a great falling off in 1908 as compared to 1907. Thus its production of iron ore in 1907 was 23,980,558 tons; the output in 1908 was only 16,662,715 tons. The manufacture of coke in 1908 was 8,169,931 tons as compared to 13,544,764 tons in 1907. The production of pig iron was 6,934,408 tons and 11,422,795 tons, respectively; of steel ingots, 7,838,713 tons and 13,342,992 tons, respectively. The manufacture of finished steel products in 1908 was a trifle less than 62 per cent. of the quantity in 1907.

It appears, however, that the total of salaries and wages in 1908, \$120,516,829, was 75 per cent. of the total in 1907, \$160,825,822. The average earnings per man decreased, being \$729.40 in 1908 against \$765.10 in 1907. This probably was due chiefly to shorter time worked by the men who were retained, there having been no general reduction of wages. The efficiency per man fell off materially. In the coal and coke properties, one man in 1907 produced 797 tons; in 1908 only 651 tons. One man produced 1457 tons of iron ore in 1907; in 1908 only 1209 tons. In the manufacturing properties, applying all the men so reported to the production of steel ingots (which, of course, is not strictly correct, but, nevertheless, is illustrative), one man in 1907 produced 88 tons; in 1908 only 66 tons.

It is probable that in the cases of labor employments which are capable of a reduction to a comparable basis of labor

efficiency, the Steel Corporation realized the same increase in 1908 that many other large concerns experienced. In other words, if one man shoveled 25 tons of coal or ore in 1907, it is probable that in 1908 one man shoveled 30 tons, more or less, because better men could be selected to do even so simple a kind of work. The decrease in efficiency in the whole business was undoubtedly a part of the price for running at a greatly reduced scale. The cut in prices that inspires consumption and enables a works to maintain its output by no means implies a corresponding diminution of profits.

The Anthracite Position

Seldom has there been so much uncertainty about a proposed strike as in the case of the anthracite mine workers. The agreement under which the mines are operated comes to an end March 31, the day on which this is written, and yet no settlement has been reached, operators and miners being apparently so far from an agreement as ever. Notwithstanding this, both parties are conducting their business without special reference to a strike or a lock-out and there is apparently every prospect that tomorrow, April 1, will see a quiet continuance of work at the mines.

The district conventions in the three anthracite districts, to which the strike question was referred by the central authority of the United Mine Workers, placed matters in the hands of a committee which recommended in effect that the demands of the miners be reiterated, especially with reference to the recognition of the Union as the central authority with which negotiations should be conducted. At the same time, from the tone of this report it was evident that the support of the Union miners was not altogether given to these demands. From the utterances of the district conventions it was apparent that many of the men were quite satisfied with the agreement formulated by the Anthracite Strike Commission in 1903, and renewed with very slight modifications in 1906. Under this agreement business has proceeded smoothly, as a rule, and the miners have done better perhaps than ever before in the anthracite region. To meet this sentiment the policy committee added to its recommendations another to the effect that the miners should not stop work on April 1, but should continue pending

further negotiations with the operators, and that there should be no stoppage of work until further orders from the union. Apparently this will be done, and work will continue in the mines unless the coal companies should order the closing of the mines on the ground that they were unwilling to continue on such an indefinite basis. The operators, however, have taken no action of this kind and the probability is that they will not.

While making no direct answer to the action of the miners' committee—which indeed was not officially submitted to them—the coal companies have issued a statement to the public. In this they say that the United Mine Workers, as at present constituted, are not a body upon which they can rely or with which they can conduct the required negotiations. The principal reason for this is that it is a body controlled by the bituminous coal miners who are in a large majority, so that the officers of the union are not familiar with the special conditions which govern work in the anthracite region. They recall the recommendation of the Strike Commission of 1903 that a separate organization should be formed by the miners to cover the anthracite mines only, free from the control or dictation of the bituminous mine workers. In this and other respects they claim that the miners have not acted in conformance with the report of 1903. They decline, therefore, positively to recognize the union and will deal with its officers only so far as they represent their own employees.

Miners and operators, therefore, are diametrically opposed on the important point. Whether it can be adjusted without an actual struggle remains to be seen. The advantage at present is clearly on the side of the operators. They have sufficient coal stored to enable them to supply their trade without interruption, even should the mines be closed for a considerable time. The season is approaching when the demand for coal is smallest. Indeed it is possible that the decision of the managers of the union to continue at work is based on some vague expectation that negotiations can be protracted until the summer season is well along and the winter demand approaches. This, however, they can hardly carry out. A further point is that the miners would entirely lack the support of public sentiment which was with them, at any rate in the first part of the strike of 1902-03; and this is an important point.

Mineral Production of Great Britain

The production of coal in Great Britain for the year, from mines coming under the coal mines act, was 267,812,852 long tons in 1907, and 261,506,370 in 1908; a decrease of 6,306,482 tons, or 2.4 per cent. A few thousand tons from open-pit workings, coming under the quarries act, are still to be reported; but this quantity is too small to affect the general result.

The other minerals won from mines falling under the coal-mines act are reported as below in long tons:

	1907.	1908.
Barium (compounds).....	10,297	6,217
Clay and shale.....	320,989	292,981
Fireclay.....	2,890,097	2,814,411
Igneous rocks.....	140	404
Iron pyrites.....	7,304	7,212
Ironstone.....	8,236,118	7,890,814
Limestone.....	22,366	15,416
Oil shale.....	2,675,779	2,891,664
Sandstone and gaster.....	128,103	110,513

Additions will be made to some of these figures—notably to iron ore—when the returns from metalliferous mines and quarries are published later. Most of the items show decreases last year.

The total number of persons employed in mines under the coal-mines act was as follows:

	1907.	1908.	Changes.
Underground.....	757,887	736,329	1. 38,442
On surface.....	182,731	191,484	1. 8,753
Total.....	940,618	927,813	1. 47,196

The number of accidents has been heretofore reported. The total quantities of all descriptions raised in 1908 were 275,534.911 tons; which gives an average of 278 tons per employee for the year.

The Mount Lyell Mining and Railway Company

SPECIAL CORRESPONDENCE

The mines of this company are situated at Mount Lyell, Tasmania, and are known as the Mount Lyell and the North Mount Lyell mines. The company has also recently acquired an extensive tract of copper-bearing country in the Norfolk range, on the west coast of Tasmania, north of the Pieman river. The work done on this new area has, however, consisted only of surface trenching and sampling. The indications are promising, but the district is difficult of access.

The report of the directors for the half-year ending Sept. 30, 1908, states that during that period 134,116 tons were won from the Mount Lyell mine, having the following average assay value: Copper, 0.85 per cent.; silver, 1.84 oz.; gold, 0.063 oz. per ton. The ore won amounting to 65,446 tons from the North Mount Lyell mine was richer, containing: Copper, 6.18 per cent.; silver, 1.39 oz.; gold, 0.007 oz. per ton. At this mine an Ilgner

electric hoisting plant has been installed which, so far, has given satisfaction. The main shaft at the North Lyell mine has been sunk to a depth of 1119 feet.

The ore reserves on Sept. 30, 1908, were as follows:

	Tons	Cu%	Ag oz.	Au oz.
Mount Lyell.....	3,382,117	0.54	1.96	0.030
North Mount Lyell	710,333	5.75	1.33	0.005

At the reduction works the usual average of four blast furnaces treated all the ores and metal-bearing fluxes, etc., supplied by the mines, in the customary manner. A new and sixth blast furnace was put into operation during the period. The tonnage treated, including metal-bearing fluxes (1562 tons) amounted to 201,697 dry tons.

The smelting results since Aug. 10, 1903, the date of incorporation of the present company, have been as follows:

Source.	Quantity, Dry Tons.	ASSAY.		
		Cu, %.	Ag, Oz.	Au, Oz.
Mount Lyell mine.....	1,463,244	0.91	1.89	0.071
North Mt. Lyell and Lyell Tharsis By-products from smelting works..	583,920	6.08	1.72	0.0052
	1,378	8.9	3.37	0.020
Total ore.....	2,048,542	2.39	1.84	0.052
Metal-bearing fluxes, silicious.....	57,614	1.49	0.38	0.0018
Cupiferous clays.....	98	0.50	0.35	trace
Purchased ores.....	3,979			
Total.....	2,110,233			

The converter products from this ore were as follows:

	Matte Treated, Tons.	Blister Copper Produced, Tons.	AVERAGE ASSAY.		
			Cu, %	Ag, Oz.	Au, Oz.
Half year to Sept. 30, 1908.....	9,484	4,450	98.74	75.65	2.032
Since Aug. 10, 1903.....	121,066	43,377	98.79	86.16	2.667

The metal output from Aug. 10, 1903, to Sept. 30, 1908, was 42,852 tons copper, 3,737.494 oz. silver and 111,347 oz. gold.

The metal output produced by the former Mount Lyell company was 48,577 tons copper, 4,121,401 oz. silver and 155,752 oz. gold. Altogether the production from these mines—excluding that from the North Mount Lyell mine prior to Aug. 11, 1903, which is not known—has been 91,429 tons copper, 7,858,895 oz. silver and 267,099 oz. gold.

For the half-year the sales of blister copper and superphosphates, less ore purchased, realized £371.615. The railway revenue was £15,852, and the profit on working account was £192,617. After writing off sundry amounts to mine prospecting, taxes and depreciation, the profit balance for the half-year amounted to £152,157. The ninth dividend is. 3d. and a bonus of 6d. per share, paid June 15,

1908, absorbed £105,000, against £210,000 for the corresponding period in 1907.

The company has paid altogether since August, 1903, 18s. 9d. per share, or £1,125,000. The previous company paid £906,574, making a total distribution of £2,121,574. Mount Lyell appears to be a very wet place, the rainfall during the six months having been 59.1 in. on 138 wet days.

Lake Superior Iron Ore

In the article on this subject in the JOURNAL of March 10, through an oversight credit was not given to the *Iron Trade Review*, of Cleveland, Ohio, for the figures there given. The *Review* has, for a series of years, collected and published these statistics of the Lake Superior iron mines, which are of great service to the trade, and are more nearly complete and reported more fully in detail than those of any other important mining region in the country.

With its issue of March 25 the *Review* sends out its usual yearly supplement, giving the production of each mine in the region yearly for 17 years, with the total output of each mine since its opening. This list includes 244 active mines, of which 110 are on the Mesabi range, 65 on the Menominee, 38 on the Marquette, 31 on the Gogebic, six on the Vermilion and three on the Baraboo range. In addition to these, total production is given for 83 mines—53 Marquette, 19 Menominee and 11 Gogebic—which have not been shippers since 1898.

In the article above referred to, a statement was given of the total shipments of iron ore up to the end of 1908. Some slight changes have been made in footing up the totals. The corrected statement is as follows:

Range:	Year Opened.	Total Ore.	Per Ct.
Marquette.....	1859	87,647,819	21.5
Menominee.....	1877	66,337,670	16.3
Gogebic.....	1884	56,732,446	14.0
Vermilion.....	1884	28,017,170	6.8
Mesabi.....	1892	167,927,113	41.2
Baraboo.....	1892	797,868	0.2
Total.....		407,060,116	100.0

The four mines credited with the greatest total production up to the end of 1908 were the Norrie group on the Gogebic range, 23,075,270 tons; the Cleveland Cliffs on the Marquette, 20,572,463; the Mountain Iron, on the Mesabi, 17,198,871; the Chapin, on the Menominee, 16,506,287 tons. The Jackson, the oldest mine in the region, shipped 3,874,153 tons up to the end of 1907, but was not a shipper last year.

Official figures for Western Australia given in the January, 1909, report of the Chamber of Mines, set the total sum of cash dividends distributed to Jan. 1, 1909, at £18,963,895. Dividends to the amount of £106,219 were paid last January.

The Railroad Systems of Northern Mexico

A Comprehensive Discussion of the Railroads in Operation and under Construction; Modern Map Authenticated by Personal Observations

BY H. A. HORSFALL*

The illustration for this article is a reduced sketch from a map of a part of Northern Mexico, recently published by me. This map has been about two years in course of compilation and is presumed to be correct, except as to some of the minor points on which accurate data has not been obtainable up to the present writing. The principal points, coast lines, etc., have been located by well determined astronomical observations; the minor points are from land surveys and railroad location maps, and some portions have been entirely redrawn from survey notes made by me in the field, during a residence of over a dozen years in this section of Mexico.

The lines of division between the various States are somewhat in doubt, so in places two lines are shown. The unshaded lines are those obtained from the land survey maps of the State of Chihuahua while the shaded lines represent the land claimed by adjoining States.

SOUTHERN PACIFIC LINES IN SONORA

In the State of Sonora the principal lines of railroad have been acquired and are now being operated by the Southern Pacific Railroad Company and comprise the following:

The Sonora Railway extending south from Nogales, Arizona, to Guaymas on the Gulf of California, a distance of 260 miles.

The Cananea, Rio Yaqui & Pacific from Empalme, the junction point, five miles east of Guaymas, runs southeasterly 64 miles to Corral, the junction point of a branch now building northward, and in operation to Cumuripa on the Yaqui river, 42 miles. This branch is also being built south from Nacozeni where it will make a junction with the El Paso & Southwestern Railroad extending to Douglas, Arizona; this portion is said to be nearly ready for operation. Nacozeni will be the terminus of this branch for the present but it will ultimately be extended to Cananea where a branch of the Cananea, Rio Yaqui & Pacific is in operation 30 miles to Naco, Arizona.

Eight miles north of Cananea, at Del Rio a branch is also in operation. This runs northwesterly to Nogales where connection is made with the Sonora Railway. Returning for the moment to the station at Corral, Sonora, we find the road continuing in a southerly direction and at 118 miles from Empalme is the station of

Navajoa, where a branch runs easterly to Alamos, 30 miles.

SOUTHERN PACIFIC SYSTEM IN SINALOA AND JALISCO

From Navajoa the line runs southeast between the coast and the foothills of high mountains and 84 miles south of Navajoa reaches San Blas in Sinaloa where it crosses the main line of the Kansas City, Mexico & Orient Railway. The road continues southward passing to the west of the mountains. It then turns more to the east and entering the foothills takes a general southeasterly direction to Culican in the State of Sinaloa the distance from San Blas being 136 miles and from the United States line at Nogales to Culican, Sinaloa, 493 miles.

The road is being built southeasterly from this point and the construction work has been completed as far as Mazatlan. The 34 miles from Culican to the Lorenzo river was to have been placed in operation Jan. 13, 1909, but I have not learned definitely that it has been done. From Mazatlan the road is being built southward toward Guadalajara in the State of Jalisco and construction is also being pushed rapidly northward from Guadalajara.

From the junction with the Mexican Central at Orendain station in the State of Jalisco, 34 kilometers to Tequila have been constructed and placed in operation by the Southern Pacific Company. Additional mileage on this section is expected to be completed in March, the whole line to be in operation by the end of the year 1912.

OTHER SONORA ROADS

The Nacozeni Railroad extending south from Douglas, Arizona, to Nacozeni, Sonora, is a branch of the El Paso & Southwestern Railroad and is an important mining adjunct. At a short distance north of Nacozeni either from Cos or Ysabal, stations on the El Paso & Southwestern, it is proposed to construct a railroad to the east into the State of Chihuahua and connecting at Guzman with the Rio Grande, Sierra Madre & Pacific Railroad. This road will be built as soon as possible, the Mexican Government being anxious to have a railroad crossing the country south of the international boundary line. Location surveys are now being made and some other point than Guzman may be selected as the junction point, in which

event the line will run further south than shown on the map.

Another short railroad called the Central Railroad of Sonora and extending 53 miles from Tonachi on the east bank of the Yaqui river to the Cieneguita mining camp, 20 miles southeast of Sahuaripa, has been in process of active construction since January 1, 1909, and is expected to be completed at an early date.

RAILROADS OF CHIHUAHUA

The State of Chihuahua is traversed by several railroads, the principal one being the Mexican Central, the main line of which was completed in 1885. This runs from Ciudad Juarez (Paso del Norte) southward across the State emerging near the southeast corner and crossing a small part of the State of Durango. It has a number of branches extending to various mining camps. The principal branch leaves the main line at Jimenez and runs west to the mining town of Parral and thence south to Rosario, Durango. Construction is in progress to points farther south and it will probably be extended before long to reach Indé and El Oro, mining camps in the State of Durango.

The other short lines connecting with the Mexican Central Railway run to various mining camps and are sufficiently well known not to need a special description. The Parral and Durango railroad runs from a station south of Parral, west and south to Ojito or Laguna; it is building an extension south of these points into the mountains of Durango with an ultimate objective point at or near the prominent mining town of Guanacevi. The Mexican Northern railway runs from Escalon station on the Mexican Central to the silver-lead mines of the Sierra Mojada, a distance of about 80 miles.

The Rio Grande, Sierra Madre & Pacific railroad starts from Ciudad Juarez (Paso del Norte) and runs in a southwesterly direction to the station of Terrazas in the central part of the State. It was formerly controlled by Col. William C. Greene, who had planned to continue the construction south to Temosachic, where connection was to have been made with the Chihuahua & Pacific railroad.

KANSAS CITY, MEXICO & ORIENT

The Kansas City, Mexico & Orient railway crosses the Rio Grande river about five miles south of the town of Presidio del Norte and will run entirely across the State of Chihuahua and into the State of

*Mining and mechanical engineer, 69 Wall street, New York.

The Engineering & Mining Journal, N. Y.

Sinaloa at its northeastern corner, thence southerly to Topolobampo bay, on the Gulf of California. There has been constructed and placed in operation up to the present time the division between Falomir and Chihuahua, a distance of 88 miles. The bridge over the Río de Conchos has also been completed and construction is being rapidly pushed eastward toward the Río Grande.

West from Chihuahua use is made of the railroad formerly known as the Chihuahua & Pacific Railroad extending nearly to Minaca, a distance of 122 miles. From Minaca the line proceeds in a southerly direction and is in operation to a station called Sanchez, situated on the crest of the Sierra Madre mountains at an elevation of 8054 feet, the distance from Minaca being 73 miles. Six miles east of Minaca the Chihuahua & Pacific railroad continues north to Temosachi, 54 miles, where it connects with the railroad of the Sierra Madre Lumber Company to Madera, a distance of about 35 miles.

From Sanchez in a southerly direction to Hornillas in Sinaloa, the road is under construction; about 60 of the 195 miles have been graded, but as this section of the road is the most difficult, progress during the last year has been extremely slow. From Hornillas south to Topolobampo, 73 miles, the road has been completed and is in operation. A branch of this railroad to reach the mining camps of Ocampo and Pinos Altos is in contemplation, but is not likely that the project will be carried through an early date.

RAILROAD LINES IN DURANGO

The railroads in the State of Durango, other than the Mexican Central, which traverses the extreme northeastern corner, are the lines of the Mexican International, extending from the city of Durango northwesterly to Tepejuanes, 135 miles, and northeasterly 157 miles to Torreon, Coahuila, with a branch to the smelting town of Velardeña. There is also a short branch from Bernajillo on the Mexican Central to the mining town of Mapimi. This branch is owned by the Peñoles Mining Company. The Penoles company also has a railroad 11 miles in length to its Ojuela mine.

There is a short line, 30 miles in length, called the Durango Central railroad, running from Conejos station on the Mexican Central to the mining town of Descubridora. A branch also extends northwest to Azufre. It is contemplated to extend the Durango & Sinaloa railroad eastward into the State of Durango. This road now runs from Altata on the coast to Culiacan, Sinaloa. Surveys completed as far as Tamazula are being extended to the mining town of Topia, Durango. Westward from Tepejuanes, the International Railroad Company has engineers in the field making surveys for a railroad to connect with the west coast.

Mining Legislation in Congress

SPECIAL CORRESPONDENCE

Although the present session of Congress was called specially to consider the revision of the tariff, several bills have been introduced relating to mining interests. They will hardly be considered at the present session.

A NEW MINING BUREAU BILL

Representative Coudrey has introduced a new bill (H. R. 1480) to establish a bureau of mines in the Department of the Interior. The bill is somewhat different from that which was pending during the last Congress, and provides that there shall be established a bureau of mines whose duty it shall be, under the direction of the Secretary of the Interior, "to make technologic investigations on mining, extracting, and utilizing, the mineral substances of the United States and the improvement of the methods and conditions under which mines are operated with a view to the prevention of mine accidents, the waste of material, the betterment of mining conditions, and the development of the various mining industries." The director of the bureau is to receive a salary of \$5000 per annum, and is to be appointed by the President and with the advice and consent of the Senate. The director is to prepare and publish for gratuitous distribution reports of the results of the inquiries and investigations conducted under the provisions of the act. He is also, with the approval of the Secretary of the Interior, to appoint for service in Washington and elsewhere such experts and other employees as may be necessary to carry out the provisions of the act. It is specified that no examinations shall be made for private persons, except where such examinations involve the question of public safety or prospecting on public lands.

MINE EXPERIMENT STATION

Representative Martin, of South Dakota, has introduced a bill to establish mining-experiment stations to aid in the development of the mineral resources of the United States and for other purposes (H. R. 2187). The measure provides that there shall be established an experiment station in each of the States and Territories where there are natural deposits of the precious metals in commercial quantities whenever in the judgment of the Secretary of Commerce and Labor such action is desirable to promote the development of the mineral resources of the United States. At each station there is to be appointed an expert geologist at a salary of \$3000 and a competent and experienced chemist at \$2000. The sum of \$5000 is to be spent each year in establishing and equipping each of the experiment stations. The stations are to an-

alyze and assay all rock, cement, clay, or mineral-bearing material that may be deposited with them for the purpose of ascertaining the exact amount of gold, cinabar, silver, copper, wolfram, tin, or any other mineral or metal known for its value in the arts and sciences and to furnish at a nominal charge a full analysis of each sample or specimen. The geologist in charge is to conduct mineral explorations when not otherwise engaged. The bill is parallel to one introduced for the same purpose last Congress, but which then received comparatively little attention.

A PROPOSED DICTIONARY

Representative Stephens has introduced a bill (H. R. 77) requiring the Geological Survey to publish 20,000 copies of a book to be known as a "Dictionary of the Minerals and Ores of the United States," which shall describe the various minerals and ores found in the United States or Territories, giving as far as practicable the locality where found and where possible a pictorial reproduction in their natural colors and such other information as would in the opinion of the director of the Geographical Survey be useful to citizens of the United States, and particularly of the mining States. Of this book 1000 copies are to be for the use of the Senate and 2000 copies for the members of the House of Representatives.

The European Zinc Convention

Paul Speier, Breslau, communicates the following additional information: The agreement is to remain in force for two years, commencing January 1, 1909. The output of the German group is limited to 255,700 tons for 1909 and 264,200 tons for 1910; the Franco-Belgium group to 174,500 tons for 1909 and 176,000 tons for 1910. The allotment for the English group has not yet been finally determined, but probably will be about 55,000 tons. The members of the several groups may arrange among themselves for changes in their allotments, providing that the total for the group does not exceed the quantity fixed by the Convention.

Curtailment of output will take place whenever the average price of ordinary brands of spelter has been below £10 for an uninterrupted period of six months; or if the total stock of spelter shows an increase during such a period. If any member of the Convention exceeds its allotment it will be subject to a penalty of 80 marks for every 1000 kg. of excess production. The Convention may be dissolved after one month's notice whenever smelters not belonging to the Convention, new smelters, cause an increase of spelter production amounting in the aggregate to more than 2 per cent. of the estimated total production.

Mine Legislation in California

SPECIAL CORRESPONDENCE

A new State mining law has been enacted by the legislature providing for the locating and recording of mining claims, recording proofs of labor, etc. Few changes are made from the Federal mining laws, but an attempt is made to prevent relocations of claims after failure to do annual assessment work, by providing that such failure deprives the locator of the right to relocate the claim until three years have expired. It is intended by this to prevent men relocating claims year after year and holding them without doing any labor on them. The State of California owns no mineral lands, however, so this legislation relates to Federal mineral lands. This provision may, therefore, be contrary to Federal mining laws and inoperative. There will doubtless be litigation on this point. The new law provides that a record of all mining locations must be made with the county recorder of the county in which the claim is situated, the fee being \$1. The boundaries of each claim are to be so defined as to be readily traced. It is also provided that after the annual assessment work is completed, within 30 days the owner must make an affidavit setting forth the value of the labor or improvements made, and record it with the county recorder. A copy of this affidavit is to be *prima facie* evidence of the performance of the labor or the making of the improvements. Copies of all records duly certified by the recorder, in whose custody such records are, may be read in evidence under such circumstances as provided by law for using copies of instruments relating to real estate, duly executed, acknowledged or proved and recorded. The provisions of the Act do not affect or abolish any mining district rules in the State, but there are now very few such districts.

These provisions about recording proofs of labor are not new in this State, but were tried and rejected. Certain mining engineers and lawyers of note found in their experience that failure to find any records of proofs of labor often prevented assurance of title to mining properties, and urged upon the legislature the passage of a law compelling record to be made of proofs of annual assessment work. A law to that effect was then passed and remained in force a few years. The miners and prospectors, however, resented the expense and annoyance to which they were put and their influence caused the law to be repealed, but it has now been reenacted. The miners contended that in the big counties like San Bernardino, Kern, Inyo, San Diego and Siskiyou, it was sometimes 100 miles to the county seat, entailing undue travel expense. In many of the little camps there were no post offices, and in others

no money-order offices, so they could not send recording fees by mail. Under this new law a miner must record his proofs of labor at the county seat within 30 days after date of location. The miners and prospectors do not look on this provision as do the mining engineers and lawyers, and consider the matter a burden.

THE EIGHT-HOUR LAW

The mine-owners and managers of the State are still exercised about the eight-hour law and are not sure what course to pursue. It is conceded that it will increase mine costs, and still more the mill costs, as the act applies to smelters and other reduction works, including quartz mills. There will have to be one more shift on the mills. The owner of one large property has decided to quit the mining and milling of the low-grade ore which prevails in his property, and to mine and mill only the higher grade. Only a part of the mine will be worked and but few of the stamps run. This will greatly reduce the labor bills, as the low-grade ore will not pay on an eight-hour basis.

Progress of the Gary Plant

The report of the United States Steel Corporation gives the following statement of work done on the new plant at Gary, Indiana:

Construction work in the development and the building of the city of Gary has been carried on vigorously. Nearly all of the dwelling houses and other buildings planned to be constructed by the company have been completed and are occupied. About 10 miles of the street paving have been completed. There have also been built over 11 miles of cement sidewalk. The entire first subdivision is now being supplied with electric light, water and gas, and is equipped with a complete sewer system. The power required for furnishing these facilities is supplied from the manufacturing plant. Within the first subdivision there have been built or are in process of building 74 business blocks of substantial construction, costing in the aggregate \$1,147,000. All of the buildings completed are occupied. In all 143 dwelling houses and flats have been completed in the subdivision by outside parties at an estimated cost of \$486,000. At this date there are approximately 60 additional dwelling houses and flats in process of building by outside parties. At Jan. 1, 1909, there had been sold by the company a total of 449 building lots and this number was increased during the month of January, 1909, by the sale of an additional 184 lots. The sales of lots now being made are largely to employees who are purchasing for the purpose of building homes. About 130 acres of land lying immediately east of the first subdivision have been sold to the American Locomotive Company for use as a manufacturing

site. It is the intention of that company to erect on this site a plant for the manufacture of locomotives which will have a capacity of 50 finished locomotives per month and will employ about 3500 men. The terminal railroad work adjacent to the plant and the city of Gary referred to in detail in the last annual report, was substantially completed during the year covered by this report.

Chronology of Mining, March, 1909

March 2—Explosion at Colliery No. 14, Pennsylvania Coal Company, Port Blanchard, Penn. Six men killed.

March 3—Eleventh annual meeting of the Canadian Mining Institute at Montreal.

March 4—Deering Coal Company, of Delaware, passes into the hands of receiver.

A round of 25 shots exploded prematurely at the bottom of a 2500-ft. shaft at the Diamond mine in the Butte district. Four men were killed.

March 5—Meeting of the anthracite district officers of the United Mine Workers of America at Wilkes-Barre, Penn., to plan for meetings with operators.

March 8—The United States loses its suit against the Standard Oil Company in the case of the \$29,000,000 fine.

March 11—The Utah legislature passed a bill giving smelters right of eminent domain in counties of less than 20,000 population. This was done over the governor's veto.

The Anthracite Coal Operators and the United Mine Workers held a conference at Philadelphia, Penn.

The stock of the Phelps-Dodge company listed on the New York Stock Exchange.

March 12—Crows Nest Pass Coal Company passes into the control of the Great Northern Railroad Company and the Granby Copper Company.

March 13—The close of a five-day session of the United Mine Workers of Indiana, held at Terre Haute.

March 14—Congress assembled in extra session to revise tariff.

March 16—A stock dividend of 60 per cent. was declared by the Consolidation Coal Company of Maryland.

March 18—The appointment of a receiver for the Idaho Smelting and Refining Company.

March 20—Explosion at Sunnyside Coal Mine, Ill., caused by a windy shot. Five men were killed.

March 23—The Tri-District convention of the Anthracite miners met at Scranton to consider the Operators' proposition regarding an agreement for the ensuing year.

March 24—A joint meeting of the Mining, Civil, Electrical and Mechanical Engineers was held in New York to discuss the conservation of national resources.

Personals

Mining and metallurgical engineers are invited to keep THE ENGINEERING AND MINING JOURNAL informed of their movements and appointments.

Frank Mills is now manager for the Gironx Consolidated Mines Company, at Ely, Nevada.

Wm. Fleet Robertson, provincial mineralogist for British Columbia, was in Seattle, Wash., recently.

Robert R. Hedley, formerly of Nelson, B. C., is now in charge of the Long Lake mine, near Sudbury, Ontario.

John Daniels, president of the Superior & Globe Company, of Arizona, has gone to the property on an inspection tour.

Charles S. Herzig, who has been engaged in work in Nicaragua for a number of months back, expects soon to visit New York.

P. G. Lidner, of New York, has gone to Central America on professional business. He expects to be absent about six weeks.

J. E. Spurr has returned to New York after a two months' trip of inspection of the properties owned by the Guggenheim interests in Mexico.

Edmund Juessen has been appointed general manager of the Pittsburg Silver Peak Mining Company, to succeed George W. Bradley, resigned.

Albert H. Fay, of the JOURNAL staff, delivered an illustrated lecture on "Life and Travel in Alaska," on March 29, in Plymouth Church, Brooklyn.

William G. Rice, president of the Superior & Boston Company, of Arizona, has returned to his home at Houghton, Mich., after inspection of the property.

O. B. Smith, of Phoenix, B. C., superintendent of the mines of the Granby Consolidated company, is spending a vacation in California and neighboring States.

B. S. Schlessinger has resigned his position as superintendent of the Comers Mines Company, Grant county, Ore., and expects to open an office in Denver.

James MacNaughton, general manager of the Calumet & Hecla, is at Old Point Comfort, Va., where he has gone to recover after his recent operation for appendicitis.

W. R. Woodford has resigned his position as vice-president of the Pittsburg Coal Company, to become president of the River and Rail Coal Company, of Pittsburg.

E. A. Holbrook, superintendent of the Daly Reduction company's mill and cyanide plant at Hedley, Similkameen, B. C., has returned after having spent a two months in Massachusetts.

Harrison Souder, superintendent of the Cornwall Ore Bank Company at Cornwall, Penn., recently returned from Cuba, where he inspected the mines of the

Spanish-American Iron Company, at Mayari and Daquiri.

J. S. Burrows, formerly engineer-in-charge of the fuel-testing division of the United States Geological Survey, has been appointed fuel expert for Castner, Curran & Bullitt, of Philadelphia.

William H. Price, chief engineer of the Meyersdale mines of the Somerset Coal Company, has been appointed assistant superintendent of the company's mines at Jeunier, Penn. Eugene C. Hostetter succeeds him as chief engineer at Meyersdale.

W. A. Carlyle, consulting engineer to the Le Roi Mining Company, Ltd., has returned to London, Eng., after having spent several weeks examining the mine at Rossland, B. C. He was accompanied by A. J. McMillan, managing director of the company.

Prof. George Lunge will attain his seventieth birthday on Sept. 15, 1909, and his friends and pupils desire that the occasion should be suitably honored. An international committee has been formed to raise a sum of money which will be devoted to the formation of a "George Lunge fund," which will be handed over to Professor Lunge to dispose of as he may desire. It is further intended that a gold medal, bearing his portrait in relief be struck and presented to him on the occasion of the celebration. Subscriptions should be addressed at an early date to Prof. E. Bosshard, Eidgenössisches Chemiegebäude, Zürich, Switzerland.

Obituary

William P. Henszey died at his residence, Philadelphia March 23, aged 76 years. He was born in Philadelphia and entered the Baldwin Locomotive Works as a draftsman in 1859. He rose gradually to be head of the designing department and finally a member of the firm of Burnham, Parry, Williams & Co., owners of the works. He was connected with many local clubs and institutions.

Dr. William Henry Wahl died in Philadelphia March 23, aged 61 years. He was born in that city and graduated from Dickinson College, later taking a course in chemistry and metallurgy at Heidelberg, Germany. He was engaged for many years as a teacher, editor and writer on technical subjects. He was best known as secretary of the Franklin Institute of Philadelphia, a position which he held from 1870 to 1874, and from 1882 to 1908, when he resigned on account of ill health. Dr. Wahl was connected with several technical journals; for two years, about 1880, he was on the staff of the ENGINEERING AND MINING JOURNAL. He was also the author of several books, chiefly on chemistry and electricity.

Waldemar Arens, general manager and financial agent for the Iron Silver Mining Company, and one of the best known mining men in Colorado, died at his home in Leadville, March 23, aged 79 years. He was born in Germany, but came to this country when a child. He was for some years in business at Detroit, Mich. In 1878 he went to Leadville as clerk and agent for Stevens & Leiter, who then owned the townsite of Leadville, and conducted the sale of lots there. Later he was made general agent for the firm, and when the Iron Silver Mining Company was organized in 1880, he was chosen secretary and financial agent. From 1885 Mr. Arens, while still retaining the title of financial agent, had active charge of the Iron-Silver operations and for 20 years as the western representative of the company, had practically full control. He enjoyed to the fullest extent the confidence and esteem of the company. Several years ago he was offered an opportunity to retire on a liberal pension but declined the offer. He seemed to have a deep affection for the old mine that he had seen grow and prosper from the very beginning, and whose vicissitudes he had followed in every phase of its career. He occupied rooms in the office of the mine in California gulch, where he spent the major portion of his time. He was a great reader and a student, fond of art and music, and had an intelligent appreciation of the affairs of the great world about him. He was highly esteemed for the integrity and the thoroughness of his work, and also for his care of the interests of those under him. He never married, and left no near relatives.

Societies and Technical Schools

Museum of Safety and Sanitation—The charter members were entertained at dinner at the Engineers' Club, New York, by Philip T. Dodge, Tuesday, March 30. An organization was perfected, with Philip T. Dodge as president, Charles Kirchoff, Richard Watson Gilder and T. C. Martin, vice-presidents, and W. H. Tolman, secretary and director.

Conservation Meeting—A joint meeting was held at the Engineering Societies building, New York, March 24, by the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. Dr. James Douglas presided, and addresses were made as follows: "Conservation of Water," John R. Freeman. "Conservation of Our Natural Resources by Legislation," R. W. Raymond. "Waste of Natural Resources," by Charles Whiting Baker. "Electricity and the Conservation of Energy," Lewis B. Stillwell.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at San Francisco, Butte, Salt Lake City, Denver, Goldfield and Paris

REVIEWS OF IMPORTANT EVENTS

San Francisco

March 26—The Inyo Development Company, which is obtaining soda from the waters of Owens lake to make soda ash is in trouble about piping the water from the lake to its factory. The waters of the lake are constantly receding, so that a considerable strip of land lies uncovered between the works and the waters of the lake. Recently other people took up the land between the company's property and the lake, and complained about the pipeline passing over their ground. Thereupon an attempt was made to get the legislature to make a change in the law governing the principle of eminent domain, which would grant authority to condemn land for pipe-lines for water used for other than domestic purposes. This attempt failed because the members of the legislature thought the purpose was to settle a dispute between two corporations. The companies will now have to fight it out between themselves.

The addition to the Tahoe Forest Reserve of 300,000 acres by the presidential proclamation of March 2 took in about 80 sections in Plumas, Sierra and Nevada counties but did not affect the latter county as much as the miners feared it would. The proposition to include all the Washington and San Juan ridges in that county together with a lot of mining towns did not go through. Mr. Pinchot agreed to the change when it was shown him that the sections named were devoted chiefly to mining with little timber. Considerable land in both Butte and El Dorado counties is, however, included, together with some mining towns of small importance.

During the past week there have been some very heavy falls of snow in the mountain sections. The snow area is more widespread than in the big storm of Jan. 24. Shasta, Siskiyou and Trinity counties got a plentiful supply which will be good for the hydraulic miners.

The famous Harrison Gulch townsite case has, after 10 years' litigation, been settled by compromise. Early settlers at this mining section of Shasta county built their dwellings, stores, etc., as suited their purpose, and finally applied for a townsite. The locators of the Bonanza mining claim also applied for a patent to their mine which included the best part of the townsite. The issues were tried out in the local land office, general land office, and on to the Secretary of the Interior. The long litigation has been to settle who had the right to

the surface ground. The Midas mine at Knob P. O., has long been a large producer and the Bonanza is developing rich ore, while other claims there are promising. The litigation has kept the whole place, mines and all, back for years.

The magnesite miners of California were unsuccessful in getting Congress to increase the duty on that mineral, as foreshadowed in a letter from here some months ago. The question of marketing magnesite in this country is entirely one of freight rates. California produces all the magnesite of the United States, but the largest consumption is in the East, and freight rates from California are virtually prohibitive. The Eastern consumers can get their magnesite much more cheaply by importing from Greece or Austria than they can by buying in this State. As there are less than half a dozen producers and many hundreds of consumers, it was out of the question to put on a high enough duty to permit shipments from California. The domestic output is from 4000 to 6000 tons annually, but could be largely increased.

The Dakin group of copper claims near Happy Camp, Siskiyou county, has been sold to John B. Farish, of Denver, for parties unknown. The price is said to be in excess of \$100,000. Happy Camp is 75 miles down the Klamath river from Yreka on the railroad, so doubtless a branch road will be built when the mines become productive. No great amount of development work has been done, but large bodies of good ore have been found. This is the largest transaction in copper mines ever made in Siskiyou county. There are other copper deposits known there, but lack of railroad facilities has kept them from being utilized.

The Minarets section in the eastern ranges of Madera county near the Mono county line, has long been known to have extensive deposits of iron ore and some copper and tungsten. The mountain peaks in that section are from 7000 to 13,000 ft. in height and the country has been undeveloped, owing to its isolated location and the height of the mountains. Paul F. Mohr, of San Francisco, who has previously investigated the Minarets, has been employed to make a systematic examination of larger bodies of iron ore and for the purpose will use diamond drills.

There is quite a little stampede in the Humbung mining district of Siskiyou county, not far from Yreka. At that

place J. A. Johnson found the Inyo mine in February and got out some good ore. In continuing work he has come across rich specimen rock in large quantity. In the same district others have made good finds this month and numbers of claims have been taken up.

Salt Lake City

March 26—The annual report of the Utah Consolidated Mining Company will be published in the near future. This company's contract with the American Smelting and Refining Company expires in about one year, and after that time the mine will ship to the new International smelter. A tunnel from the mine in Bingham cañon to Pine cañon on the Tooele side is projected. The mine is now in excellent condition, and of late some rich orebodies have been developed. Jesse Knight has definitely announced that the men holding an option on the Tintic smelter and the Colorado mine are representing the Cole-Ryan Syndicate. This option expired on March 20, but has been renewed. The price involved for Colorado stock is said to be about \$4 per share, and that for the smelter about \$1,000,000. The copper furnace at the Tintic smelter was blown in March 22 and is now running smoothly. The Grand Central, Carisa, Ajax, Mammoth and other Tintic properties will probably ship to this smelter.

For the first time since December, 1907, the Daly-West Mining Company has announced a dividend. It is dividend No. 47 for 30c. per share, or \$54,000, and is payable April 10, 1909. During 1908 the Daly-West marketed 12,760 tons of crude ore and 4424 tons of concentrates. The crude ore carried 343,376 lb. of copper, 2,683,830 lb. of lead, 454,149 oz. of silver and 441.86 oz. of gold, which brought \$225,780. The concentrates carried 116,346 lb. of copper, 2,305,472 lb. of lead, 211,476 oz. of silver, and 150.62 oz. gold, which brought \$150,621, making a total of \$376,402 for ores sold.

At the West Quincy annual meeting, G. D. B. Turner again came into control of this company. Of 270,000 shares issued 215,000 were represented. J. R. Rand was elected president; George W. Morgan, vice-president; H. C. Gaw, secretary and treasurer. J. R. Rand, H. F. Sewall, H. E. Moore, George W. Morgan, R. E. Miller, M. H. Sowles and J. R. Clawson constitute the new board of directors. The

company owns valuable ground in Park City.

The Tintic Empire Company, of Tintic, the Mountain Lake Extension Company, and the Camp Bird Company, of American Fork, the Cedar-Talisman Company, of Beaver county, and the East Tintic Gold King Company, have been listed on the Salt Lake Exchange. The Tintic Empire and Mountain Lake Extension are each incorporated for 1,000,000 shares of 10c. each; the Camp Bird and East Tintic for 1,000,000 shares of 5c. each, and the Cedar-Talisman for 1,000,000 shares of 50c. each. The Tintic Empire controls six unpatented claims, and the Mountain Lake Extension owns 14 patented and five unpatented claims. J. W. Knight is president and F. O. Frick, secretary. The Camp Bird and the East Tintic each control five unpatented claims. The Cedar-Talisman Company owns five patented and 10 unpatented claims in Beaver county. Joseph Geoghegan is president and H. Barnett, secretary and treasurer.

The Silver King Coalition Mines Company has declared a quarterly dividend of 15c. per share for \$187,000, payable April 1, 1909. The Utah Consolidated has also posted a quarterly dividend of 50c. per share, payable April 15.

Butte

March 25—Since it has been concluded that the Amalgamated mines are not going to curtail their output the mining industry has taken on a more settled aspect in the Butte camp. It is reported that the Pitts-mont Copper Company is about to change hand, or in other words, that the controlling number of shares are under option to W. A. Paine, of Boston. The Pitts-mont Copper Company succeeded the Pittsburg & Montana Copper Company, and was reorganized May 1, 1908, at which time the name was changed and the capitalization was reduced from \$30,000,000, at a par value of \$100 per share, to \$11,000,000, with a par value of \$5 per share. During the past several months a 250-ton concentrator has been completed, and many improvements made to the smelting plant. Four hundred and fifty tons daily are being mined and treated, and it is understood that new and large bodies of ore are being opened up. During the past week news of a big strike comes from the Davis Daly property. It is stated that a crosscut from the 1400 level of the Colorado has intersected and cut through a 20-ft. vein, which averages from $3\frac{1}{2}$ to 4 per cent. copper, with some silver and gold.

Amalgamated is working the Poulin through the Buffal shaft. Operations at the Anaconda are still somewhat retarded on account of the gases. The St. Lawrence and Neversweat are being worked, however, and as the levels of these three mines are all connected, the gases from the old mine fires are allowed to escape

through the Anaconda shaft while the good air is supplied to the workings through the Neversweat and St. Lawrence shafts. The Anaconda company's shaft on the Right Bower claim has reached a depth of 225 ft. The Badger State shaft of the Boston & Montana has reached a depth of over 1000 ft. Boston & Montana is shipping about 3500 tons daily to Great Falls, which smelter is being enlarged and will eventually have a capacity of 5000 tons. The Britannia mine in the southwestern portion of the camp is being unwatered.

The Original and Gagnon mines have opened up better ore in the lower levels than at any other place in the mines; in fact, all of the large mines within the known copper belt, have opened up good ore in the lower levels.

The Butte Coalition company has practically made a new mine out of the Minnie Healey and has opened large bodies of ore in the recent developments. There are several development companies pushing work with much energy among which are the Butte Superior, Tuolumne, Davis Daly, Elm Orlu (the property of W. A. Clark), and the Butte Balaklava. The Anaconda company is also sinking a shaft on the Right Bower claim in Meaderville. The Boston & Montana company is sinking on the Badger State, which adjoins the Jessie claim of the North Butte company.

Denver

March 26—The Gold Dollar Consolidated Mining Company, of Cripple Creek has just issued its regular quarterly report to its stockholders, disclosing a satisfactory condition of affairs, and announcing a dividend of $\frac{1}{2}$ c. per share, payable April 10. Announcement is made of the granting of two important leases in the district, one on the Shurtloff, owned by the Findley company, for a period of eighteen months, to Asmussen and associates, and the other, for five years, on the entire property of the Free Coinage Gold Mining Company, to G. R. Woodin, representing, it is said, Boston capitalists. Machinery is now being installed at the Pinto shaft on this property.

From Tenderfoot hill comes the report of a strike on the fourth level of the main shaft of the Hoosier, situated about two miles northeast of the town of Cripple Creek. A group of claims between Long Hungry and Pony gulches, about eight miles south of the town, are being vigorously worked, thus showing that the circle of activity is gradually being extended beyond the recognized gold-bearing area of the Cripple Creek district.

The Vidler tunnel through Argentine Pass, above Georgetown, is being advanced at the rate, so it is reported, of seven to eight feet per day, and the breast of the Eastern portion is now 4300 ft from the portal. It is rumored that for-

eign capitalists have become interested in the Topeka group, one of the former large producers of Russell Gulch, and operations are soon to be resumed after an eight years' period of idleness.

A gold bar, weighing 1173 oz., and valued at over \$20,000, was shipped a few days ago to the Denver mint by the Fifty Gold Mines Corporation, being the product of a 30 days' run at that company's mill, on ore produced from the Bobtail and Fisk veins at a depth of 1400 feet.

In Cripple Creek the deep drainage tunnel has now been driven 635 ft.. The distance from the portal to the breast is 5383 ft., and the distances from the headings in the intermediate shaft are 801 and 751 ft. A strike worthy of recording is in the Doctor-Jack Pot; some leasers have exposed at a depth of 240 ft., 4 ft. of ore, the first two carloads of which ran \$80 per ton.

The litigation between the Ajax and the Uinta companies, which has been pending for a number of years, preventing the working of some rich ground near Victor, Colo., has been amicably settled, and all the property is now controlled by a new company called the Ajax-Uinta Gold Mining Company. It will be worked under the lease system. A rich orebody is said to have been entered at the 1400-ft. level of the main shaft of the Vindicator. The new shoot was opened on the main Vindicator vein 260 ft. north of No. 1 shaft, and is between 3 and 4 ft. wide. The Vindicator company is maintaining a steady production of 1500 tons a month from the main workings, and lessees on the Vindicator No. 2 and Hull City shafts ship 750 to 1000 tons, averaging close to \$30 per ton.

At Rico, in the San Juan region, the chief mines are now included in the United Rico Mines and the Wellington and Logan groups. The first, which has for a long time suffered under extravagant and inefficient management, is now being run under a new manager on intelligent and economical lines, with a superintendent who has had much experience in Leadville and Aspen, and who understands the somewhat puzzling formation and ore occurrences at Rico.

In the Cripple Creek district, the annual report of the El Paso Company says that during the last year, the property, which was worked under the leasing system, produced gold ore valued at \$422,663.

Goldfield, Nevada

March 23—The production of the Goldfield mines for the week ending March 20 was 6500 tons valued at \$332,000. The details for the consolidation of the Hibernia and Conqueror properties have been practically completed and the new organization will be known as the Conqueror Consolidated Mining Company. The new

company is incorporated under the laws of South Dakota with a capital stock of 2,000,000 shares, par value \$1 each. Messrs. Wingfield, Nixon and Hennessey are heavily interested.

A reconnaissance survey of the proposed Ely-Goldfield railroad is now in progress to be followed immediately by preliminary and location surveys. Manager John Ryan, of the Tonopah and Tidewater road, states that the road will be completed and in operation by the end of the year.

By a clever ruse, the Governor caught the opposition napping, and on the night of March 16 introduced a bill abolishing the State board of assessors and creating a new commission composed of the governor, attorney general and State comptroller which has the power to assess railroads, telegraph, telephone and power companies.

The suit instituted by the Goldfield Consolidated against the Frances Mohawk Mining and Leasing Company was called on March 22 in the district court. The Consolidated asks for \$125,000 damages, alleging neglect of the lessees in complying with the terms of their lease and claiming that by insufficient timbering the property was damaged to that extent. H. P. Bryant, counsel for the plaintiff and J. W. Finch, former general manager of the Consolidated, arrived in Goldfield last week to take part in the suit. As an outcome of this suit, D. Mackenzie filed a suit on the March 19 against the Mohawk Mining Company, George Wingfield and James R. Davis. Damages of \$100,000 are asked against Wingfield and Davis who acted as bondsmen for the Mohawk company, and \$400,000 against the Mohawk company together with \$2000 attorney fees. The plaintiff claims that his business was damaged greatly by the action of the defendant company in tying up the funds of the Frances Mohawk company; that the suit was of malicious origin, the Mohawk company being aware that D. Mackenzie and company were not responsible for the affairs of the Mohawk company.

Ore shipments from Tonopah for the week ending March 20 were as follows: Tonopah Mining, 3150 tons; Belmont, 700 tons; Montana Tonopah, 645 tons; MacNamara, 300 tons; Jim Butler, 160 tons; West End, 150 tons; Midway, 100 tons; total 5205 tons, worth \$130,000.

Toronto

March 26—The Ontario government has disposed of 130 lots in the Gowganda township for the total sum of \$17,664. The sale was by tender, 250 lots in all being offered of which 120 were withdrawn, the bids not being considered sufficiently high. The highest price secured for any lot sold was \$412 and the lowest accepted was \$25, the average figure being \$136 per lot. Recently a strong deputation from

northern Ontario waited on the government and urged the immediate extension of the Canadian Northern Railway from Sellwood to Gowganda and an appropriation for a permanent wagon road.

The exportation of natural gas will be discontinued at the end of March, Hon. Wm. Templeman, Canadian Minister of Mines, having decided that the present supply must be conserved for Canadian use. The only company now holding a license to export, piped, during last year, about 250,000,000 ft. to Buffalo. Its license expires at the end of March, and its renewal has been refused.

In the Ontario Legislature a bill has been introduced by Hon. Frank Cochrane, provincial minister of mines, to amend the law respecting mine accidents and the operation of mines. It is based on a report of personal investigations into mining conditions by Mine Inspector Corkill. Safeguards as to the use of explosives are made compulsory, and miners are prohibited from drilling at the bottom of old drill holes where there are frequently old charges of unexploded dynamite. The Inspector is to be in attendance at all inquests in case of mining fatalities to assist in bringing out the evidence, the lack of technical knowledge on the part of coroners sometimes resulting in the suppression of essential facts. A record must be kept of all scaling operations and crossheads must be so constructed that the bucket will stop immediately on the crosshead striking the shaft. Penalties for violations of mining regulations are considerably increased and in cases where neglect to comply with them is considered deliberate a sentence of imprisonment may be imposed.

Johannesburg

March 2—The new gold law of the Transvaal is now in force. One of its most widely applicable provisions is being advertised, so that persons affected may be fully warned. This relates to the forfeiture of claims upon which the license fees have not been duly paid. Under the old law such claims were advertised for sale by auction, and even then, as a rule, the registered holders could recover possession by paying up arrears. Under the new law, however, there will be no public sales, but the ground will revert automatically to the Crown when license payments are three months in arrears.

The duties of professor of mining in the College of Johannesburg are of rather an exacting order, but the authorities in charge have made the position attractive by fixing the salary at £1500—about the salary of the manager of a large mine—permission being given also to do consulting work in season. The position requires not only technical knowledge, but also practical experience and some familiarity with local conditions. A feature of the

College is found in the night classes, in which men who are at work during the day can qualify themselves to pass the government examinations required for appointment as mine foremen, superintendents, and other responsible positions.

Paris

March 22—Debate on Ouenza affairs in the French Chambers has been put off until after Easter holidays, the reason for this delay being that the government is about to modify its first scheme and grant the Ouenza ores access to both Bizerta (Tunisia) and Bône (Algeria) harbors. It desires to facilitate the supplying of coal to Bizerta harbor by providing coal steamers with return freight. From the Ouenza-Bône railway (about 140 km.) a line would branch off to join the existing Tunisian line at Nebeur. Rates of railage would be the same for both lines. Moreover, the mining concession of Bou-Kadra, neighbor to the Ouenza concession, but independent, would have to forward all its ores through Bizerta, thus insuring a yearly ore-traffic of 700,000 or 800,000 tons.

The consortium concerned in the Ouenza had pledged itself to build the railway line from Ouenza to Bône at its own expense and to undertake large improvements in the latter harbor. The government's new scheme raises loud protests in Algeria, both from the people and the authorities, and the Chambre de Commerce of Bône has decided to suspend payment of contributing funds to the state until further orders.

Several attempts are being made in New Caledonia for treatment on nickel ore (garnierite) by the erection of blast furnaces at Duimbo Point, near Nouméa. Two other schemes contemplate turning to account hydraulic power in the island, one by fitting the Plaine des Lacs with a large dam. The other plan is to utilize the Taô falls. Gagings carried on for three years estimate the power available on the latter spot at 15,000 h.p., upon which the necessary equipment for working 2000 h.p. has just arrived. By vote of the Conseil General of New Caledonia, submitted for approval to the Conseil d'Etat, a premium of 0.10 fr. per kg. of metal will be paid to producers, up to the amount of 50,000 fr. (\$10,000) for each concern.

A tornado has made great havoc on the eastern coast of New Caledonia and heavily injured the aerial wire-rope tramway of Compagnie Le Nickel, lately the subject of an illustrated article in the JOURNAL.

An Australian syndicate is boring for petroleum at Ouen-Toro on the western coast of Caledonia. A thick bed of soapstone, emitting inflammable gas, has been struck at a depth of 820 ft., and water brought up by spoon contains oil.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Alaska

Alaska Treadwell—February: 240-stamp mill crushed 35,336 tons ore; estimated value of bullion, \$51,543. Saved 700 tons of sulphurets; estimated value, \$33,124. Working expenses, \$83,762.

Ester Creek—On Feb. 25 the first stamp mill in the Tanana began operations near Fairbanks. E. W. Griffin, mayor of Chena, says the quartz has been found in places from Ester creek to No. 8 above on Fairbanks.

Gold Bullion—This Seattle company is installing a two-stamp battery at Cook's inlet. A good shoot of gold-bearing quartz is reported.

Arizona

COCHISE COUNTY

Calumet & Arizona—The annual meeting of the stockholders will be held at Bisbee April 12.

Southern Arizona Smelting Company—This company is at present producing at the rate of about 1,250,000 lb. of copper per month.

Paradise District—The Turkey Creek Mining and Development Company was recently organized and incorporated. H. J. Freede, president, and M. J. Donahoe, secretary and treasurer. Main office is at Douglas.

GILA COUNTY

Arizona-Michigan—Work on the three-compartment shaft is progressing rapidly under Manager S. W. Clawson, formerly of the Copper Queen at Bisbee. The shaft has now reached a depth of 125 feet.

PINAL COUNTY

Ray Central—Papers have been recorded in Florence consummating a deal whereby Adolph Lewisohn, of New York, acquired the property of the Kelvin Calumet Mining Company.

YUMA COUNTY

Golden Star—The property of the company is near Polaris in the Kofa mining district, and consists of 21 mining claims and 7 placer claims. The mine has been opened by two shafts, one 130 ft., and the other is 300 ft. deep, exposing the vein the entire depth. The fourth level is now opened 150 ft. in length. The vein is 8 ft. wide, from which ore is being sent to the mill. The 50-ton cyanide mill is

treating 1300 tons per month, yielding \$40 to \$45 per ton. Machinery is now on the ground to increase the capacity of the mill to 75 tons per day. The company is capitalized at \$2,000,000, divided into 400,000 shares, par value \$5.00. D. M. Hyman, president; J. L. Tilton, secretary and assistant treasurer.

Yuma Copper—This is a new company organized to develop 600 acres of mineral land. Samuel Brady, superintendent of the Michigan Copper Mining Company, is president.

California

AMADOR COUNTY

Argonaut—Some of the machinery at the shaft at Jackson is being replaced, and a larger compressor is being put in. The full milling capacity will soon be in operation.

BUTTE COUNTY

Magalia Ridge—Work is steadily prosecuted on the old Matheson mine. At the Hupp, which is now under bond, an incline is being run. At the Cole good ore is being taken out. The Mammoth Channel Gold Mining Company has installed a new hoist and is enlarging its shaft. The Atlas Mining Company will shortly begin work on its lease on the Wilson & Brown property.

CALAVERAS COUNTY

Levaggi Estate Company—The old steps and drifts of the Newman mine are being cleaned out, preparatory to resuming operations.

EL DORADO COUNTY

Ogden—At the El Dorado mine a wide vein of good milling ore has been opened.

DEL NORTE COUNTY

Cleopatra Development Company—This new company is about to begin mining operations in the northern portion of the county.

TRINITY COUNTY

Yellow Jacket—In this district some important developments are being made, not only in the Yellow Jacket group itself, but in the mines adjoining.

TUOLUMNE COUNTY

Kelts—The shaft of this mine, Soulsbyville, is being cleaned out and, after it is retimbered, thorough development of the property will begin.

North Fork—A new 50-h.p. hoist is being installed with some other machinery at this mine.

YUBA COUNTY

Tarr—This company, which is about to work the old Blue Point or Paddy Campbell mine near Smartsville is preparing to start active operations as soon as the weather will permit.

Colorado

LAKE COUNTY—LEADVILLE

Louise—A drift on the lower level is in a body of ore 4 ft. wide. The ore is a lead sulphide, carrying gold, and was found close to the Bald mountain fault.

New Monarch—From the Cleveland and Winnie shafts the company is shipping about 1500 tons per month of different grades of ore. As the Yak tunnel has drained the country in the neighborhood of the Monarch shaft, the company has decided to resume work in the near future.

Yinnie—Another pocket of ore was opened in this Breece hill claim during the week and the company is shipping about 30 tons of ore daily. The property is worked from the Yak tunnel.

A. Y. & Minnie—From California gulch this property is shipping daily 150 tons of lead and zinc sulphides to the Western Chemical Works, Denver. The dump is being treated in the mill and a good grade of concentrates is shipped.

R. A. M.—The drift connecting this shaft with the Pyrennes has been completed and now both properties are supplied with plenty of good air, which will permit the orebodies above the water level to be worked successfully.

Matchless—A body of good ore, carrying chlorides, has been opened in one of the lower levels and shipments are now going out daily.

Progressive—Arrangements are being made to sink the shaft deeper and to install heavier machinery to handle the water.

OURAY COUNTY

Camp Bird—During the month of February the mill ran 21 days, crushing 4944 tons of ore and producing 9715 oz. of bullion and 375 tons of concentrates. The expenses of the company were \$43,135. During the month, 581 ft. of development work was done.

Indiana

GREENE COUNTY

None of the miners in the Linton coal-field worked Tuesday, March 23, because of the local option election. A large majority of the miners voted to put the saloons out of the county. Thursday was one of the biggest pay days the miners have had for some time, the total reaching \$145,000, or more.

VIGO COUNTY

The Indiana Coal Operators' Association has voted to help State Mine Inspector Epperson have Terre Haute made a station for the relief appliances which the Government has indorsed and which have been tested recently at the University of Illinois. President Van Horn, of the Indiana Mine Workers indorses the plan.

Maryland

Consolidation Coal Company—This company reports for the year 1908 receipts of \$3,691,746, a decrease of \$952,058 from 1907. Income from investments was \$361,983, making a total of \$4,053,729. Working expenses were \$2,647,469; taxes and other charges, \$572,000; a total of \$3,219,469, and leaving a surplus of \$834,260. From this dividends amounting to \$820,000 were paid. The company mined 1,748,233 tons of coal in 1908, and lessees on its property 399,939 tons, a total of 2,139,172 tons. The Cumberland & Pennsylvania Railroad, owned by the company, carried 3,935,593 tons of coal during the year.

Michigan

COPPER

Keweenaw—The drift from the 13th level of the Medora shaft has encountered the west fissure vein, but there is little copper at the point of intersection. This fissure was opened at the 11th level where it was well charged with copper. The company will in all probability conduct further exploratory work on the Kearsarge lode during the coming summer. Regular shipments continue to the Phoenix stamp mill, which is treating about 100 tons daily, yielding about 16 lb. of mineral to the ton.

Isle Royal—This company continues sinking its shaft to open the Baltic lode. It is now down about 230 ft. Its further development will be awaited with interest.

Calumet & Hecla—Six additional Chilian mills have been started at this company's new regrinding mill, and others will follow as soon as they can be assembled and put in shape. This plant, when completed, will contain 48 Chilian mills and 136 Wilfley tables, all to be driven by eight 250-h.p. 2080-volt induction motors.

Franklin—The stockholders' annual meeting will be held April 21, 1909.

Elm River—The annual meeting of the stockholders will be held April 21, 1909.

IRON—MARQUETTE RANGE

Kloman—An option on this property at Republic has been taken by the Cleveland-Cliffs Iron Company, the stipulated price being \$125,000. The property will be explored by drilling during the coming season.

Minnesota

IRON—CUYUNA RANGE

Arrangements have been made by Cuyler Adams, who has been for several years conducting explorations in the Cuyuna district, with the Rogers-Brown Ore Company to incorporate a company to build a railroad from Duluth to Deerwood in the center of the district. When communication is assured, steps will be taken to open one or more mines on the range.

Mississippi

LAUDERDALE COUNTY

Coal is reported to have been found near Lauderdale. The discovery is now being investigated by men from Birmingham, Ala. It is supposed to be an extension of the coal deposits in the western part of Alabama.

Montana

BUTTE DISTRICT

Tuolumne—A recent report shows that the sum of \$301,110 was received from the sale of stock; total disbursements up to the present date aggregate \$183,076, with a cash balance in the treasury of \$117,133. The shaft has been sunk to a depth of 1200 ft., and sinking will continue until the 1,400 level has been reached.

Minneapolis & Radersburg Mining and Milling Company—Articles of incorporation have been filed in Silver Bow county. The capitalization is 500,000 shares, par value \$1 per share. The incorporators are W. L. Hall, Alexander Hall, and J. H. Maloney, well known Butte mining men. The property of the company is located near Radersburg, Montana.

MISSOULA COUNTY

Saltese District—This district, which has lately been opened up by the entrance of the Chicago, Milwaukee & Puget Sound railroad, is showing much mining activity. The Silver Bar Mining Company is driving a tunnel, which will cut the vein at a depth of 700 ft. The vein shows a large outcrop carrying small percentages of lead, iron carbonate and silver.

Bryan Mine—With perhaps the exception of the Monitor, this is the most thoroughly developed property in the district. The vein has been developed to a depth of over 400 ft., and a large body of silver-lead ore has been exposed.

JEFFERSON COUNTY

Corbin-Wickes Copper—A 12-in. vein of chalcopryite is being worked on the 235-ft. level. Plans are being made to sink the shaft to the 500-ft. level.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Goldfield Consolidated—A strike remarkable both for size and richness of the orebody has been made on the Combination No. 1 claim. The orebody is just north of the Combination mill practically in the center of the claim. At present it is opened on the fourth and fifth levels and exploratory work on the sixth indicates the workings to be close to it on that level. The body is irregular in shape and varies in width from 30 to 50 ft. and as now exposed has a length of 151 ft. The same quality of ore also occurs in a raise now 35 ft. above the fourth level. Shipments are now being made to the Western Ore Purchasing Company, in carload lots, which return from 80 to 105 ounces per ton.

Consolidated Red Top—An orebody has been encountered in the crosscut on the 300-ft. level, and while penetrated 60 ft. the footwall has not yet been reached. The ore improves as the footwall is approached. The first carload shipped returned \$83 per ton. The company has secured an extension of six months extending from Aug. 1, 1909, to Feb. 1, 1910.

Grizzly Bear—This lease situated on the similarly named claim of the Consolidated property has added a compressor plant to its equipment and power drills will be installed. The shaft is now 330 ft. deep and it is expected that the Clermont vein will be encountered at a depth of about 400 feet.

Gold Bar-Victor—Power drills are to be used in the Victor claim as soon as connection can be made with the Gold Bar compressor plant. Shipments are being made regularly.

Penn-Florence—A shipment of 15 tons of \$60 ore was made last week. The ground which is the same as the old Zinn-Florence lease is now being worked by Capt. Thomas Hooper and associates, who are also operating the Goldfield White Rock Mining Company. The ore is being extracted from the 200-ft. level.

Little Florence Leasing Company—Exploratory work is being carried on at the 357- and 500-ft. levels where strong and well defined low-grade ledges are being followed.

ESMERALDA COUNTY—RAWHIDE

Rawhide Queen—On the Kerns No. 2 lease, the oreshoot has been found on the lower level, and shipments are regularly made to the Dayton mill. The Kerns No. 1 lease is taking out average shipping ore, and the milling ore is be-

ing thrown on the dump. A rich body of ore has lately been cut on the 130-ft. level of the Grutt Balloon Hill lease. The vein is 6 ft. wide, and this promises to be the most remarkable strike yet made in Rawhide. The Dromiac lease continues to sack ore for shipment. On the St. Ives lease drifting for the rich shoot of the Grutt Balloon Hill continues. Much work is being done, and lately several claims lying in the east Walker river country have been added to the company's holdings.

HUMBOLDT COUNTY—MAZUMA

Seven Troughs District—Three mills are operating and a fourth ten-stamp mill is now under construction by an English syndicate. Seven companies are now shipping ore. These are: Seven Troughs Mining Company, Seven Troughs Coalition, Mazuma Hills Mining Company, Wihuja lease, Harris lease, Reagan lease, and the Badger Hill. The Kindergarten mill is at present running on Harris lease ore, and the Wihuja will have a shipment as soon as the cleanup of the Harris takes place. The Mazuma Hills mill is crushing Reagan lease ore. All properties produce high-grade ore.

NYE COUNTY—TONOPAH

Montana Tonopah—During the past week 205 ft. of new ground was broken. The mill crushed 645 tons of rock from the mine and 385 tons from the MacNamara with an extraction of 90 per cent. The contract for treating the ore from the MacNamara ends this week, after which the mill will treat the company's product exclusively. The semi-monthly clean-up last week resulted in 23 bars of bullion weighing 88 lb. per bar, which together with the concentrates were shipped to the Selby smelter.

Tonopah—Sinking in the Mizpah shaft was resumed on March 11. The shaft, which is of three compartments, will be sunk at the rate of about 20 ft. per week. The new pump at the 1200-ft. level is giving satisfaction. A sump of 12,500 gal. capacity has been made on the 1200 level. It is emptied twice a day. At the mill 97 out of the 100 stamps dropped continuously last week, crushing 3100 tons of rock, averaging \$23 per ton. Ninety-four bars of bullion valued at \$800 each and 24 tons of concentrates worth \$375 per ton were shipped, making the total production for the week \$84,200.

MacNamara—The directors, at a meeting held in San Francisco, March 6, declared a second dividend of 1c. per share payable April 5.

WHITE-PINE COUNTY

Nevada Consolidated—January shipments, 1,451,000 lb. copper, February, 1,035,000 lb., March 1 to 20, 1,086,000 lb.; this is at the rate of 1,680,000 lb. per month.

Ohio

BELMONT COUNTY

Plans are under discussion for the consolidation of the Lorain Coal and Dock and the Youghiogheny & Ohio Coal companies, the combined companies to have \$20,000,000 capital. The proposed new company will own 31,000 acres of land, on which seven mines are now in operation.

Ohio Coal Operators' Association—This association was organized at Columbus, Ohio, recently. The officers chosen were: President, F. M. Osborne, Cleveland; vice-president, Richard Enderlin, Chillicothe; treasurer, H. H. Heiner, Columbus; secretary, Howard Mannington, Columbus. Executive board: C. L. Cassingham, H. E. Loomis, Herbert Sternberger, J. C. Berring, H. H. Heiner, Edward Johnson, F. M. Osborne. The organization is composed of all coal operators of the State, and will deal with questions affecting the coal industry of the State as a whole, and not take up questions concerning districts as such. The State has been divided into 12 districts, each of which will have a separate but affiliated organization which will deal with all matters with which the district alone is concerned. Each district will elect one member to represent it on the executive committee of the State organization, and this body will have full charge of all rates, wages, legislation and other questions which affect the mining industry of the State.

Oklahoma

JOHNSON COUNTY

A deposit of zinc ore has been found near Ravia. The district is entirely new, and a few shallow open cuts show zinc and lead sulphides intimately associated with dolomite, flint and sandstone. The ore occurs in the vicinity of the contact between the dolomite and granite. Drilling with churn drills is to be started at once, to determine the extent of the deposit.

Oregon

LANE COUNTY

Combination—Clark Brothers, owners, are building a concentrator. Silver-gold ore is now being blocked out.

Crystal Consolidated—A suit has just been filed in the circuit court wherein the Wynne Hardware Company, of Cottage Grove, Oregon, is plaintiff, and Benjamin Lurch, Geo. M. Holland, Ben Pitcher, all of Cottage Grove, defendants. Plaintiffs claim that they were given a judgment on foreclosure proceedings against certain mining claims and mining property of the Crystal Consolidated Mining Company some time ago, and that the defendants have relocated the claims and done assessment work.

Pennsylvania

ANTHRACITE COAL

A bill said to have been originally prepared by James Roderick, chief of the State Department of Mines in Pennsylvania, has been submitted to the State Legislature for consideration. The bill takes from the electors of anthracite counties the power of choosing mine inspectors and rests this authority in the Governor. It is provided that in January 1910, and every four years thereafter, the Governor shall appoint five citizens to be known as the Mine Inspectors Examining Board. Two of the members are to be mining engineers and the three remaining committeemen are to be miners of five years' actual practice.

BITUMINOUS COAL

It is reported that J. V. Thompson, of Uniontown, who has recently purchased some large tracts of coal land in Greene and Fayette counties, is negotiating for their sale to United States Steel Corporation interests.

Somerset Coal Company—This company reports for 1928 total earnings of \$1,736,797, a decrease of \$632,068 from 1927. Other income was \$71,903, making a total of \$1,808,700. Working expenses and depreciation were \$1,396,421; taxes and fixed charges, \$266,365; making a total of \$1,662,786, and leaving a surplus of \$145,914 for the year.

South Dakota

LAWRENCE COUNTY

Branch Mint—The operating company has shut down again after operating on the Richmond dump for several months. It is evident that the operations on the scale followed proved unprofitable. It is reported that the company proposes to raise additional funds to work the mine as well as the dump.

Elliptic—This company has been prospecting its ground north of the Homestake by sinking two diamond drill holes. One from the bottom of the 600-ft. shaft has struck some free-milling ore at a depth of 1200 ft. from the surface. The second, put down 1000 ft. south, has sunk 1100 ft., but found nothing.

Gilt Edge-Maid—The mine and mill have been leased to M. E. Hiltner and A. B. Dill. The former was for a number of years superintendent of the Wasp mill and has recently been in charge of the Gilt Edge-Maid mill.

Tinton—It is reported that work will be started on the tin ores at Tinton this Spring and that machinery has been ordered to increase the capacity of the concentrating plant.

Hutchins Consolidated—Secretary M. L. Gordon, of Gillette, Wyo., is making arrangements to thoroughly open up the property in the Bear gulch. The company is newly organized and holds good ground.

Tennessee**POLK COUNTY**

Ducktown Sulphur, Copper and Iron Company, Ltd.—This company, which has its headquarters in London, England, has offered for subscription in that city an issue of 48,779 ordinary shares of £1 each at the price of 25s. per share. These shares are to have a fixed preferential dividend of 10 per cent. per annum up to Dec. 31, 1909, payable on the amount from time to time called up. After Jan. 1, 1910, the shares will rank with the existing ordinary shares. The proceeds of the present issue are to be applied for completion of installation of sulphuric-acid plant.

Utah**UTAH COUNTY**

Dutchman—This lease has been unable to ship owing to the bad condition of the roads, but 140 tons of high-grade ore are ready for shipment as soon as the roads become passable.

SALT LAKE COUNTY

Utah Copper Company—March production is expected to be about 4,500,000 pounds.

TOOELE COUNTY

Buffalo Consolidated—A winze has struck the extension of the rich orebody of the Lion Hill Consolidated Company. A lower tunnel now in 500 ft. will be driven a distance of 200 ft. farther to tap ore at an additional depth of 300 feet.

Rodenhouse—A drift from the 75-ft. level shows 6 ft. of good copper ore carrying some gold and silver. Four carloads of ore averaging 5 per cent. copper are now on the dump.

International Smelting and Refining—The contract has been let for the structural steel for the new smelting plant. Work on the railroad is being pushed, and it will probably be completed May 1. When the road is finished the smelter construction will be carried forward as fast as possible.

Washington**KING COUNTY—BERLIN**

Apex—This mine has just shipped a car of ore to the Everett smelter. Eighteen men are at work. This force will be increased upon the completion of the surface tram connecting the mine with Berlin, a mile and a half of which remains unbuilt.

SNOHOMISH COUNTY—GRANITE FALLS

Wayside—Work continues in the encouraging vein struck a few weeks ago.

SNOHOMISH COUNTY—INDEX

Bunker Hill—Diamond-drill boring last week showed up a 29-ft. lode of chalcopryrite and marcasite, carrying about 5

per cent. copper and substantial gold and silver content. The vein encountered is the continuation of the one which was worked at a depth of 140 feet.

STEVENS COUNTY

Northport Smelter—This smelter, which is owned by Le Roi Mining Company, is to be closed early in April, owing to the lack of sufficient ore of payable grade from Le Roi mine, Rossland, B. C., to keep even one furnace regularly supplied. Custom ores have been received from about a dozen small mines, but the total receipts are not large enough to supply the needs of the works. The shutdown is not regarded as permanent—only until such time as the ore supply shall be large enough to keep at least one furnace in regular operation.

West Virginia

Fairmont Coal Company—This company reports for 1908 gross earnings of \$3,401,815, a decrease of \$1,458,512 from 1907. Income from subsidiary companies was \$510,398, making a total of \$3,912,213. Working expenses, taxes, depreciation, etc., were \$3,342,499, leaving a surplus of \$569,714. Dividends paid were \$249,000, leaving \$329,714 to add to surplus.

CLAY COUNTY

Lackawanna Coal and Land Company—This company, organized by F. W. Tibbetts and associates, of Philadelphia and Scranton, Penn., has secured a tract of 22,500 acres in Clay county, extending into Nicholas county. The purpose is to lease tracts to coal operators on a royalty basis.

Wisconsin**ZINC-LEAD DISTRICT**

Platteville—The Kohinoor Blende Company has leased its property to the Wisconsin Zinc Company; upon satisfactory examination, a mill will be erected. The property is opened up by 100 ft. of drift, showing a body of sheet zinc, and is considered one of the best prospects in the district. The Wisconsin Zinc Company is making preparations to remove the 100-ton mill from the Royal to the Mitchell Hollow. The Graham-Stevens has completed its incline shaft and is producing again. The Lyght is cementing its mill pond, breaking of which forced the company to close down soon after the mill was completed last fall. The shaft just finished on the Ellesworth farm showed 9 ft. of ore ground in sheet form. The Big Tom prospect, on the Thomas land, struck good sheet jack recently in the glass rock.

Wyoming**CARBON COUNTY**

Penn-Wyoming—With the final payment of \$16,831, the United Smelters, Railway and Copper Company recently

took up notes and other evidence of indebtedness amounting to \$1,390,789, principal and interest which were given by the Penn-Wyoming Copper Company and its subsidiary companies.

Canada**BRITISH COLUMBIA—ROSSLAND**

Le Roi—A number of men who had been working at this mine have been discharged. The managing director, A. J. McMillan, who returned to Rossland from England on March 6, has made the following announcement: "The exploration work carried on for several months past in the lower levels of the mine has not, up to date, proved the extension of the rich orebodies found and opened up toward the end of last year. This is, of course, disappointing, and as it is not economical to ship ore and carry on exploration work on a small scale, it has been decided to suspend operations until arrangements are made for carrying out a large and comprehensive scheme of exploration and development, such as will thoroughly test undeveloped portions of the property, and particularly the south vein from the present 1650-ft. level to an additional depth of about 1000 feet."

BRITISH COLUMBIA—QUEEN CHARLOTTE ISLANDS

The Granby Consolidated Mining, Smelting and Power Company, Ltd., has bonded and made a first payment on a group of copper claims near Tasso harbor, Moresby island, of the Queen Charlotte group. Surface indications on this property and other mineral claims in the vicinity are promising, but not much development work has yet been done.

BRITISH COLUMBIA—BOUNDARY

British Columbia Copper Company—The following notice has been issued by J. E. McAllister, general manager: "Notice is hereby given that, owing to the unfavorable conditions of the copper market the mine and smelter of the British Columbia Copper Company, Limited, will close on or before April 1, 1909, for an indefinite period." This will throw some 400 men out of work. The Greenwood miners' union made a voluntary offer to the company to accept a 10-per cent. reduction in wages, but the company took no action.

Silver King—The Kootenay Development Syndicate, organized last year in London, by M. S. Davys and associates, has commenced mining at this mine, near Nelson, which was operated for years by the Hall Mining and Smelting company. Several months ago the syndicate secured the property under lease and option, and unwatering was commenced. Three levels having been pumped out, the production of ore has been commenced under the

direction of Louis Pratt, of Nelson. The ore contains values in both silver and copper; the production during eleven years to end of 1907 was 202,745 tons, averaging about 3.5 per cent. copper and 21 oz. silver per ton.

BRITISH COLUMBIA—VANCOUVER

Tece Copper Company—February. Smelter ran 19 days, treating 5250 tons of ore, producing 560 tons of matte.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ending March 20 were: Buffalo, 45,350 lb.; Chambers-Ferland, 117,440; Crown Reserve, 115,520; King Edward, 44,130; La Rose, 195,000; Nipissing, 351,680; Nova Scotia, 79,420; O'Brien, 77,200; Temiskaming, 40,000; Temiskaming & Hudson Bay, 60,000; Trethewey, 56,620; total, 1,182,300 pounds.

Cobalt Lake—A new vein about 12 in. in width has been struck in the crosscut from No. 6 shaft, about 600 ft. in beneath the lake. It carries smallite, niccolite and native silver, and the wall rock for a foot on either side is shot with native silver. The crosscut is being run close to the McKinley Darragh property at the 135-ft. level in the hope of picking up some of its veins.

Temiskaming—No. 3 vein has widened from 8 in. on the 200-ft. to 12 in. on the 250-ft. level. In drifting at the latter level an 18-in. vein was struck, yielding rich ore.

ONTARIO—HASTINGS COUNTY

Canadian Pyrites Syndicate—Lot 9 in the 10th concession of Madoc has been secured, and a plant installed under the management of George H. Gillespie. Shipments will be made to Buffalo.

Palmier Pyrites Mine—This property in Madoc is being opened up. A 24-ft. vein of pyrites has been exposed, assays of which show from 40 to 50 per cent. sulphur with a slight trace of gold.

ONTARIO—MONTREAL RIVER DISTRICT

Moose Horn—The new plant, comprising a three-drill straight-line compressor and two 50-h.p. boilers is now being installed.

Ottise-Currie—A nine-drill compressor with boilers and other machinery has been installed.

ONTARIO—SOUTH LORRAINE DISTRICT

Lang-Husselt Syndicate—A syndicate of Cobalt capitalists, headed by Mayor Lang, has bought two groups of claims, comprising in all 20 locations in the neighborhood of Front lake in the South Lorrain district for \$75,000 cash and stock considerations. It is intended to develop the properties until shipments can be made and then to organize a company.

NOVA SCOTIA

Dolphin Coal Company—The annual statement shows net profits for the year

of \$2,680,202, as against \$2,094,539 in 1907, the balance remaining after paying interest and dividends being \$1,600,162. The total surplus for the year is \$4,253,471 against \$2,828,308 at the close of 1907. There is cash on hand to the amount of \$2,175,884. The output for 1908 was 3,555,668 tons, as compared with 3,541,253 for 1907. The demand for the company's coal for steam continues satisfactory, and the market has been maintained, in spite of competition by American operators.

YUKON—WHITEHORSE

Burwash Creek—Pay gravel has been struck on a dozen claims on which work has been done all the winter. The pay-streak is 7 ft. deep and 60 ft. wide, and the dirt runs from 10 to 30c. per pan. In some places it is 30 ft. down to bedrock. Twenty men have worked on Burwash since last fall and all have located the paystreak. Jacquot Brothers, on Claim 12, above the cañon, have the best showing, their dump panning up as high as \$50 per man per day. Gold-bearing gravel has also been found on other creeks in the vicinity. Freight is high, 12c. per lb. being charged from Whitehorse to Burwash.

Mexico

CHIHUAHUA

San Francisco del Oro—A reorganization was recently perfected in London and operations under the direction of James E. Hislop will be resumed about May 1.

San Toy—Regular shipments from this company's Sta Enlalia mines have been renewed, the ore coming from both the Galena and Juarez mines. The wooden terminal station, recently destroyed by fire, will probably be replaced with a steel structure.

Parral Output—The production of the Parral camp for the week ending March 19 consisted of 4050 tons of smelting ore and 5450 tons of milling ore.

Concheño—Corrigan, McKinney & Co., operating under the name of Cia Beneficiadora de Concheño, have resumed development operations on property recently forfeited by the defunct Greene Gold-Silver Company.

Zinc Mill—Lawrence Reed, representing the concern which owns the Potter process, has lately toured this and adjoining States to ascertain the ore supply and the best location for reduction works. Chihuahua or Torreon will probably be selected.

San Timoteo—T. A. Ripperdan, manager, is receiving bids for a small modern concentrating plant. A reverberatory furnace is now being built. The property is in the Uruachic section in the western part of the state.

Humboldt Exploration—This lately organized New York company is said to be

meeting with some financial encouragement in its efforts to assume control of the properties of the Greene Gold-Silver Company.

Hinds Consolidated—Oscar E. Slincock, managing director, is enlarging the operating department.

Rio Plata—On account of shortage of water the mill was operated only one-half its capacity during February. Net returns on shipments for the month were \$30,700.

Batopilas—This company is reported to be once more in bonanza ore.

MEXICO

Esperanza—Two rich gold-bearing quartz veins are reported on the ninth level. One is 3½ ft. and the other is 5 ft. wide.

OAXACA

Tehuantepec Silver—John T. Judd, treasurer, reports that a 60-ton cyanide plant is under construction. During the year ending March 1, 1909, 787 ft. of adit work were done at a cost of \$4.80 per foot. Size of adit, 6.5x9.75 feet.

SONORA

Babacanora Mine—Recent development has opened some old workings below the caved zone, in which has been found a body of silver ore blocked out in 25-ft. blocks. Alfred Tellam is superintendent.

San Lorenzo—Martin Dickinson has sold this mine to Eastern parties, who have done 200 feet of development work. John A. Rice, of El Paso, Texas, is consulting engineer.

San Agustín—This old mine, near Siquipa, is being worked after 18 years shut-down, and is showing some high-grade silver ore.

Monte Vista—It is reported that Charles F. Hanson, of Douglas, Ariz., has raised \$75,000 to put in a milling plant and build a road to the property.

Greene Cananea—Six of the eight furnaces are in blast. March production was approximately 3,800,000 lb. of copper.

TAMAULIPAS

La Esmeralda—It is reported that 250 ft. of adit and drift work have been done during the last four months. Zinc-silver-lead ore has been encountered.

Africa

WEST AFRICA

Gold production, including Gold Coast and Ashanti, was 21,303 oz. bullion in February. Total for two months ended Feb. 28 was 50,108 oz. bullion in 1908, and 44,220 oz. in 1909; decrease 5078 oz. The bulletin reported this year was equal to \$802,070, or 41,750 oz. fine gold

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, March 31—The coal trade in the West shows little change since our last report. A small improvement is reported from most of the distributing centers in the demand for steam coal. Much less contracting has been done than is usual at this season of the year. This is probably due to the fact that large consumers believe that they will do better by trusting to the open market than by closing season contracts.

The bituminous coal trade in the East is also without much change. Business improves slowly so far as individuals are concerned, but shows quite an advance in the aggregate. Mines, however, are not running full time, as a rule, and there is room for considerable betterment.

The anthracite trade is in the air. There is a total lack of certainty as to strike conditions. The miners have proposed to continue work pending an adjustment, but it is not at all certain that the operators will continue to keep their mines running without an agreement. Whether April 1 will pass without a stoppage of some kind is uncertain, even at this late day. A fuller statement of the anthracite conditions will be found on another page.

The coke trade is gradually getting into shape. The overproduction of a few weeks ago is being worked off, which will leave the market on a better basis.

A report comes from Denver that the Wooten Fuel Company has closed a contract with the Navy Department for 500,000 tons of southern Colorado coal to be delivered at the Mare Island navy yard during the coming year. The report has not yet been confirmed.

Western Coal Troubles—In Salt Lake City, March 29, the United States District Court fined the Union Pacific Railroad Company, the Oregon Short Line, the Union Pacific Coal Company, and J. M. Moore, manager of the Union Pacific Coal Company, \$3000 each. Everett Buckingham, division traffic manager of the Oregon Short Line, was fined \$1000. The companies concerned were convicted of discrimination in refusing to haul coal bought by a Salt Lake coal firm.

In the same court the Utah Fuel Company pleaded guilty to the fraudulent acquisition of 14,040 acres of coal land, paid a fine of \$8000 and \$192,000 for the coal extracted, and relinquished the land.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to March 20, short tons:

	1908.	1909.	Changes.
Anthracite.....	1,138,464	1,411,375	D. 97,089
Bituminous.....	7,278,297	7,635,042	I. 356,745
Coke.....	1,588,092	2,183,632	I. 595,540
Total.....	10,004,853	10,860,049	I. 855,196

The total increase this year to date was 8.5 per cent.

Coal production of the State of Washington for the years named is reported as below, in short tons:

	1907.	1908.	Changes.
Shipped.....	3,458,276	2,745,698	D. 712,578
Local trade.....	135,762	103,834	D. 31,928
Used at mines.....	128,396	127,898	D. 498
Total.....	3,722,434	2,977,490	D. 744,944

The production of coke was 48,798 tons in 1907, and 37,381 in 1908; decrease, 11.47 tons.

Corrected statement of shipments by Southwestern Interstate Operators' Association for years named, short tons:

	1907.	1908.	Changes.
Missouri.....	2,884,471	2,370,022	D. 514,449
Kansas.....	6,454,419	5,122,509	D. 1,331,910
Arkansas.....	2,286,983	1,948,911	D. 338,072
Oklahoma.....	3,000,465	2,728,292	D. 302,173
Total.....	14,656,338	12,169,734	D. 2,486,604

The total decrease in shipments for 1908 was 19.6 per cent.

New York

ANTHRACITE

March 31—While the trade is all at sea about the continuance of work in April, business is going on as usual and it looks as though no stop was expected. This is so much the case that the companies have issued their usual order for a discount of 50c. a ton on April sales of prepared sizes. These are in abundant supply, but there is a scarcity of steam sizes for the reasons already noted in this column. Small sizes are being held at the mines to provide fuel for pumps, etc., in case of a stoppage of work.

Prices for April are \$4.25 for lump and \$4.50 for egg, stove and chestnut f.o.b. New York harbor points. For small steam sizes prices are nominally unchanged as follows: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points. Advances ranging from 10c. per ton up are asked in many cases by commission merchants.

BITUMINOUS

The soft-coal market still shows an irregular condition, orders coming in

bunches to be followed by a period of quietness. Nevertheless, the books for March as a rule show a considerably larger total of sales than in February. Contract making continues rather slowly and up to date probably 60 per cent. of the usual contract business has been closed. Prices on this trade are as a rule from 15 to 20c. below last year.

For current trade prices are rather low; thus run-of-mine gas coal has sold on a basis of about 65@70c. per ton at mine and slack at 55@65c. The lower grades of steam coal are bringing 90c.@\$1 at mine with the better grades selling up to \$1.50, at mine.

Trade in all the consuming districts is about the same, New York harbor and the Sound taking coal a little more freely, while the far East is showing signs of life. All-rail trade is better than Coastwise. Transportation is fully up to schedule and cars are in abundant supply.

In the Coastwise trade, vessels are in good supply—too good in fact, as they are hunting for business. Current rates for large vessels from Philadelphia are: Boston, Saco and Portland, 70c.; Lynn, 75@80c.; Newburyport, 80c.; Providence, New Bedford and the Sound, 55c. per ton.

Birmingham

March 29—No improvement whatever is noted in the coal market. There is a curtailment of production; several coal mines in this district have been cut down to four days work a week and others to less. There are few sales being made. A report that the Galloway Coal Company had sold 210,000 tons of coal, delivery during the balance of the year, was confirmed by one of the owners, but with the statement that the order was just one-half of the amount that the purchasers of the same took last year. The coke production is being cut down materially.

Chicago

March 30—In general the coal trade remains firm and unchanged. The bituminous market is adjusting itself to spring conditions in which fine coals take a stronger position and lump sizes a weaker, relatively, and there is a general lull in steam consumption, owing to the waiting attitude of manufacturers. Steam trade is increasing much more slowly than was hoped for at the beginning of the year. Domestic coals are very quiet; not even the announcement of the customary 50c.

discount on anthracite for April has sufficed to book any large amounts for that month's deliveries. Contract business is not large, and shows the growing tendency of large consumers to rely on the open market.

Illinois and Indiana coals are freer from demurrage troubles than they have been for many weeks, the cause being reduced shipments to this market. Lump and egg sell at \$1.75@2.40; run-of-mine, \$1.65@1.75, and screenings at \$1.25@1.55. Illinois operators have become watchful of the market and apparently do not intend to ship in coal that cannot be sold readily.

Eastern coals are a good deal stronger because of restricted shipments. Smokeless is stronger than it has been for several months, and Hocking shows but slight demurrage evils. For smokeless lump, Pocahontas and New River, \$3.30 is obtained, and for run-of-mine from the same mines the price is \$3.15. Hocking brings \$2.90@3.15, with demand bettering. Gas coals are quiet, Youghiogheny selling at \$3.15 for 3/4-in. Anthracite sales are dull.

Cleveland

March 30—Lake trade is still uncertain, and the start will not be early. Some engagements of vessels have been made, but there is no rush. Reports of large stocks on the docks in the Northwest are not encouraging.

Local business is looking up on the steam side slowly, but is looking down on domestic coal. Prices are still low. Hocking brings \$1.35 for lump at mine, and \$1.10 for run-of-mine. Massillon at mine brings \$2.50 for lump and \$2.35 for run-of-mine.

Indianapolis

March 30—The anthracite coal situation is being watched as closely by the bituminous operators in Indiana and Illinois as by the operators in the East. The large dependence on anthracite coal in the Middle West was not fully appreciated until the strike six years ago in the anthracite field. The demand for soft coal increased until buyers flocked to the coal centers of Indiana and paid large advances to secure coal. The profits to operators were large. Many of them now think the Indiana industry was badly handicapped as a result because too many new mines were opened in the next few years. While the Indiana operators would profit by a strike in the anthracite region there is a general feeling that there will be none. President Lewis is regarded as a shrewd and long-headed man and not in favor of a strike at present.

Pittsburg

March 30—Conditions in the coal trade remain practically unchanged. A number of contracts for coal for the Northwestern

markets were booked by the large Lake shippers. While the Lake season will open officially on April 1 there will be no coal for shipment and it is not known when shipments will begin. There is no iron ore to be brought down and as coal is the return cargo for the ore boats it may be late in the spring before active shipments begin. Last year no coal was shipped until about the middle of June. Operations at the railroad mines continue at something less than 50 per cent. while the river mines are still running full. Prices remain on the basis of \$1.15 a ton for mine-run coal at the mine and slack is strong around 70 cents.

Connellsville Coke—There is no demand for coke and extremely low prices are named for spot shipment. Furnace coke can be had at \$1.50 to \$1.60 and the latter price is quoted on contracts running to July 1. Foundry coke for prompt shipment is down to \$1.90 and from \$2 to \$2.15 is quoted on contract.

The *Courier* in its summary for the week gives the production in both regions at 251,261 tons. Shipments were 8993 cars as follows: To Pittsburg, 3172; to points west of Pittsburg, 5955; to points east of Connellsville, 766 cars.

Foreign Coal Trade

German Coal Trade—Imports and exports of fuel in Germany, month of January, metric tons:

Imports:	1908.	1909.	Changes.
Coal.....	543,960	509,153	D. 34,807
Brown coal.....	696,429	577,861	D. 118,568
Coke.....	43,351	54,794	I. 11,433
Briquets.....	15,821	17,051	I. 1,230
Exports:			
Coal.....	1,402,912	1,734,924	I. 332,012
Brown coal.....	1,926	2,211	I. 285
Coke.....	309,925	270,327	D. 39,598
Briquets.....	122,857	109,523	D. 13,334

Coke exports this year included 1509 tons to the United States.

German Coal Production—Coal production of German Empire, month of January, metric tons:

	1908.	1909.	Changes.
Coal.....	12,879,152	12,010,715	D. 868,437
Brown coal.....	5,702,911	5,596,416	D. 106,495
Total mined.....	18,282,063	17,607,130	D. 674,933
Coke made.....	1,858,993	1,776,373	D. 82,620
Briquets made.....	1,412,431	1,483,552	I. 71,121

Of the briquets reported this year 1,172,597 tons were made from brown coal, or lignite.

Russian Coal Production—Production in the Donetz basin in Russia in 1908 is reported as follows: Anthracite, 2,214,042 metric tons; bituminous, 10,352,061; coke, 1,437,286; total, 14,003,389 tons.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on March 20: Best Welsh steam, \$3.42; seconds, \$3.30; thirds, \$3.18; dry coals, \$3.48; best Monmouthshire, \$3.00; seconds, \$2.94; best small steam, \$2.16; seconds, \$1.92. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, March 31—The iron and steel markets show signs of improvement, but in a rather irregular way. An attempt is being made in some quarters to give the impression that marked dullness still prevails, but it is evident that much of this is due to a desire to bring pressure to bear upon the tariffmakers at Washington. It is not to be denied that there is not a generally active market; but it is also true that in certain lines there is a degree of activity which points toward a more general improvement.

In pig iron there has been some business in foundry iron, although it has been in moderate quantities for early deliveries, as has been the case for some months past. Outside of foundry there is not much doing, very little basic or gray forge being sold. The hesitation on the part of the merchant furnaces and their disinclination to press sales is largely due to the fact that no action has yet been taken looking toward the fixing of prices of Lake ore for the coming season. There is an evident intention on the part of ore sellers to hold last season's prices, if it can possibly be done.

In finished material the most active market is in structural steel. Many contracts are coming forward, both small and large, and the volume of business done has been considerable. It is reported that very low prices have been made on this class of steel and persons interested in building projects are taking the opportunity. A large business has also been done in bars by brokers and agricultural-implement makers, and low prices have been made both on iron and steel bars. In some other branches of the trade, such as wire, the large makers are rather holding back and seem unwilling to make the reductions which buyers expect.

Rail orders are still held back, although several small orders have been placed amounting to a considerable total. The larger companies, however, are evidently expecting some adjustment of prices. Quite a number of orders for railroad bridges have been placed and some also for new equipment.

A London despatch of March 30 reports that a contract for rails and rail-joints for the Glasgow street railroads has been awarded to the Lorain Steel Company, Lorain, Ohio. The quantity is not stated; the price is given at £6 2s., or \$27.68 per ton, delivered at dock, Glasgow harbor. The bid was £2 below English mills.

Improvements in Steel Works—The Jones & Laughlin Steel Company, of Pittsburg, has floated successfully an issue of \$15,000,000 bonds, the proceeds to be used in improvements and additions to the works. The expenditures will extend over some time.

Baltimore

March 30—Exports for the week included 2001 tons steel rails to Buenos Aires. Exports included 11,250 tons iron ore from Cuba.

Birmingham

March 29—There are pessimists and optimists in the Southern iron market. There is no business being transacted now worthy of mention and as far as some of the manufacturers can see it there is no promise of any improvement in conditions in the near future. There is yet considerable iron being shipped out; it is on old orders. The cast-iron pipe interests are melting a large quantity of iron. There is to be further curtailment in production during this week. The Southern iron companies are receiving some inquiries for iron, the greater portion being for small lots. No sales are being made, however, which shows that the consumers are only testing the market. The quotations are still weak though one or two companies in this section are holding up to \$12 per ton, No. 2 foundry. There is no trouble, however, in getting iron at \$11.50 per ton and a lower price will not be turned down by some manufacturers.

Chicago

March 30—The pig-iron market continues depressed, and for finished materials the conditions and prospect are not much brighter. Melters are apparently waiting on general business developments and the settlement of the tariff question by Congress; everybody, high and low in the trade, is hesitating. Sales continue steady of such amounts of iron as are needed to carry along current requirements of foundrymen; for the second half of 1909 there are numerous inquiries, but they are not promising of immediate contracts. In structural materials and railroad supplies there is some activity. Here, again, there is a waiting policy.

Pig iron brings \$11@11.50 Birmingham (\$15.35@15.85 Chicago), for delivery within the next three months, with a possibility of a lower price on any large contract. The bottom of the market would seem to be reached by this quotation. Northern sells for \$16@16.50, being in general much more stable than Southern, production of local furnaces being kept down and the demand being steadier. What a large contract would bring in the matter of prices can only be guessed; to judge from conditions the price would be very low, and delivery could be as suited the purchaser.

Philadelphia

March 31—It would be safe to omit any reference to the local pig-iron market this week. Inquiries show that very few sales have been made and those merely

for piecing out purposes. A few lots of special brands have been sold and there are inquiries for additional supplies from concerns using only special makes. The tendency, if there is any discernible, is downward in prices, but this is more apparent than real. Southern foundry has been offered in this market this week at prices which would debar sales by Eastern furnaces, which fact has a depressing effect.

Plates—A fair business has been done this week for delivery in this territory.

Structural Material—A further shading has been made in structural material.

Scrap—Scrap iron is dull. Yard stock is in better demand than anything else. Heavy steel scrap is under inquiry but buyers will not pay the prices asked.

Pittsburg

March 30—Considerable new business in several finished lines has been booked by large interests and it is reported that the already low prices have been seriously shaded. Merchant-steel bars are said to have been sold by the principal producer at a cut of \$2 a ton, or at 1.10c. instead of 1.20c., the recognized price. Contrary to custom and the policy of the Steel Corporation, H. P. Bope, first vice-president and general manager of sales of the Carnegie Steel Company, issued a statement denying the report and insisting that bar prices were being firmly maintained. Despite this and other denials, sales of 500-ton lots and less are said to have been closed on the low basis. Shading to the extent of \$4 a ton and more in shapes also is reported and there is every evidence that someone is cutting the price. It is reported from the East that as low as 1.06c. at mill has been done on shapes. The leading bar-iron interest has made a concession in prices in western territory. Heretofore the price for iron bars in Chicago and other points in the West was the Pittsburg base rate with the freight of 18c. per 100 lb. added, but frequently 15c. was the rate given. Now while the price is 1.10c., Pittsburg, the rate in Chicago and St. Louis is 1.30c., the iron, of course, being furnished from one of the Western mills of the company. Agricultural implement makers are feeling the market, and it is believed will place some contracts although they usually do not buy until later in the season for the year beginning July 1. It is understood a concession in steel bars will be made on these yearly contracts, but so far no important contracts have been closed.

The National Tube Company has booked a number of small orders and several large ones. Among the latter is one calling for 30 miles of 16-in. pipe for the Philadelphia Company, and 60 miles of 16-in. pipe for the Kansas Natural Gas Company. This last-named concern is in the market for additional tonnages

and may add to its purchase at any time. It is reported the Republic Iron and Steel Company will erect a large pipe plant at Youngstown and become an active competitor for the merchant-steel pipe trade. It also will make wrought-iron pipe. The plans have been practically completed but the details are not made public.

Pig Iron—The largest inquiry in the market for a long time came yesterday from the Crucible Steel Company of America. It calls for 3600 tons of chill-cast bessemer for April delivery. The contract will be placed this afternoon or tomorrow. Actual prices of pig iron cannot be given in the absence of transactions but quotations seem to be a trifle firmer this week as follows: Standard bessemer, \$15@15.25; malleable bessemer and basic, \$14.50@14.75; No. 2 foundry, \$14.50; gray forge, \$13.50; all at Valley furnaces.

Steel—No sales of billets are recorded except under sliding scale contracts. It is reported that the \$23 price can be shaded. Sheet-bars and tin-bars are still quoted at \$25.50, but sales are said to have been made at less. Plates remain at 1.30c. and merchant-steel bars at 1.20c., but lower prices are being made on some orders.

Sheets—New business is being booked and prices are firm, black sheets being quoted at 2.30c. and galvanized at 3.30c. for No. 28 gage.

Ferro-Manganese—There is but little demand and prices are unchanged at \$43 @43.50, Pittsburg.

Metal Market

New York, March 31—The metal markets are still quiet, but rather better than they were a week ago, with some speculative tendencies.

Gold, Silver and Platinum**UNITED STATES GOLD AND SILVER MOVEMENT**

Metal.	Exports.	Imports.	Excess.
Gold.			
Feb. 1909..	\$ 8,860,814	\$ 3,676,413	Exp. \$5,284,401
" 1908..	1,367,697	2,847,138	Imp. 879,536
Year 1909..	16,726,170	6,996,596	Exp. 9,729,574
" 1908..	2,411,797	13,646,617	Imp. 11,234,820
Silver.			
Feb. 1909..	4,862,649	3,508,881	Exp. 1,353,868
" 1908..	4,108,774	4,451,755	Imp. 657,019
Year 1909..	9,594,643	7,173,633	" 2,221,020
" 1908..	8,266,918	7,073,629	" 1,193,289

Exports from the port of New York, week ended March 27: Gold, \$9,603,250, chiefly to London; silver, \$892,529 to London and Paris. Imports: Gold, \$623,077, which includes \$389,000 French gold in transit to Havana; silver, \$199,866, from the West Indies and Mexico.

Gold and silver movement in France, month of January:

	Imports.	Exports.	Excess.
Gold.. Fr. 111,406,000 F.	4,685,000 Imp.	Fr.106,721,000	
1908..	30,689,000	2,275,000 Imp.	28,313,000
Silver..	8,507,000	4,375,000 Imp.	4,132,000
1908..	8,123,000	21,069,000 Exp.	12,946,000

Imports of nickel and copper coins, 8000 fr. in 1908, and 4000 fr. in 1909; exports, 26,000 fr. in 1908, and none this year.

Gold—The prices in the open market in London are unchanged at 77s. 4d. per oz. on bars and 76s. 5d. per oz. for American eagles. The Bank of England is taking most of the gold arriving, though some has gone to Germany. In New York the export movement has stopped for the present, but a renewal is expected.

Platinum—The business in platinum is quiet, although sales are a little better than in the early part of the month. Dealers' prices are unchanged at \$23.50 per oz. for refined platinum, \$26 for hard metal and \$10@21 for scrap.

Our St. Petersburg correspondent reports under date of March 18 that the market is dull and inactive, metal being offered by agents without sales. Prices quoted for crude metal, 83 per cent., are 505.15 rubles per zolotnik, Ekaterinburg, and 20,300/20,500 rubles per poond at St. Petersburg; equivalent to \$19 and \$20 per ounce, respectively. The report concerning the mines of Prince Demidoff-San Donato in the Ural is contradicted.

Silver—The recent steadiness in the silver market has been due to moderate buying by China. A shipment of £370,000 to Shanghai some two weeks ago is an indication of what has been going on in this direction. Since that shipment there have been further purchases on China account.

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis New York, cash. The price of cathodes is usually 0.125¢ below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—In the week of March 25-31, there was some heavy selling for export in the early part, when certain first hands were rather aggressive. Later on domestic manufacturers entered the market to a considerable extent, and the demand for export continuing, sellers were able to realize an advance in price, and sales were made in which all of the agencies participated. All are now freely offering electrolytic copper at 12 3/4¢, delivered, 30 days, or a little less than 12 3/4¢, cash, New York. Some business in Lake copper has been done through the week. Casting copper has been rather active at prices close to those realized for electrolytic.

Summarizing the week, there is a decided improvement in the general condition of the market. Consumption is slowly but surely expanding. The fears of an indefinite increase in the visible supplies are, on this account, being dissipated, and this in a measure explains the large absorption of copper that has again taken place this week, particularly before sellers raised their price, consumers both in this country and abroad having been liberal buyers. The activity has considerably subsided at the higher prices which ruled near to the close, but the tone remains firm at 12 3/4¢@13¢ for Lake copper; 12 1/2¢@12 3/4¢ for electrolytic in ingots, cakes and wire-bars. The average of the week for casting copper has been 12 1/4¢@12 1/2¢ cents.

The standard market in London showed evidences of persistent buying throughout the week, and the advance which was established between the closing of March 26 and the opening on Monday has been fairly well sustained, quotations at the close being cabled as £57 for spot, £57 13s. 9d. for three months.

Refined and manufactured sorts we quote: English tough, £61 10s.; best selected, £60 10s.@£61 10s.; strong sheets, £72 10s.@£74 10s.

Exports of copper from the United States, two months ended Feb. 28: Metal, 79,063,640 lb.; in ores and matte, estimated, 2,517,000; total, 81,580,640 lb. Imports: In ores, 8,274,861 lb.; in matte, 2,440,346; metal, 37,223,034; total, 47,939,141 lb. The exports were 33,641,400 lb. in excess of the imports.

Visible stocks of copper in England and France are reported by Henry R. Merton & Co., London, at 52,355 long tons on March 15; an increase of 60 tons over Feb. 28. These stocks include 7475 tons afloat from Chile and Australia.

At the beginning of March there was

a continuation of the large sales inaugurated during the last week of February, but these soon ceased. On March 1 sellers raised their prices, thinking that the news of the previous sales would stimulate purchasing by the manufacturers in this country, but their hopes were disappointed. During this period of activity upward of 100,000,000 lb. of copper is believed to have been sold, but the sales were to a large extent made with foreign speculators, and it gradually came to be recognized that these did not help the situation very much. From the maximum price of 12 1/2¢@12 3/4¢ for electrolytic created in this way, the market gradually eased off under absence of buying orders and more or less pressure to sell on the part of producers, and by the middle of the month the price for electrolytic had fallen to 12 3/4¢. This again led to some large purchases from Europe, and afterward American manufacturers entered the market to some extent. Producers took advantage of their appearance to raise prices slightly, but the latter could not go far, the bulk of the transactions during the latter part of March being made at 12 3/4¢. The attempt to lead manufacturers to buy largely upon a rising market thus failed, as it was bound to do, purchasers being conversant with the large accumulation of unsold metal on both sides of the Atlantic, and the probability that the supply was increasing farther during March, the exports for the month, like those in February, being at a comparatively low figure. After a lull in the trading there were some more heavy transactions in the last week of the month, certain agencies being still free sellers at about 12 3/4¢, and in the last two days some good orders were placed at about 12 3/4¢, while copper was freely offered by all the agencies at the equivalent of about 12.60¢. The total sales for the month, during the three periods of buying activity, were without doubt in excess of the production, but their delivery is extended over April and May.

Tin—Large purchase orders which were cabled from this side toward the end of last week, supplemented by reports of comparatively small shipments from the East during the month of March, brought about an upward movement in the London market. The advance amounted to about 4s per ton, and the market closes firm at £134 5s. for spot, £135 10s. for three months.

While dealers have taken a little interest in this market, consumers have not been tempted by the advances, and continue their hand-to-mouth policy. Quotations are made at 20.75 cents.

Lead—A very brisk business has been transacted. Orders have been coming forward in larger volume from all quarters, but most noticeable is the increase in the business placed by the cable manufacturers, which has been lagging behind for some time. All offerings were

readily absorbed, and when the largest interest raised its price on Monday, the other sellers quickly followed suit, and the market is now firmly established at 4.10c., New York, 3.92 $\frac{1}{2}$ @3.95c., St. Louis.

There is a better tone in London, and the market has crept up from day to day, closing firm at £13 13s. 9d. for Spanish lead, £13 16s. 3d. for English lead.

Spelter—This metal has been an exception to the general rule. The transactions were altogether of a retail character and quotations remained unchanged through the week at 4.60@4.62 $\frac{1}{2}$ c., St. Louis, 4.75@4.77 $\frac{1}{2}$ c., New York.

The closing of the London spelter market is cabled as £21 7s. 6d. for good ordinaries, £21 12s. 6d. for specials.

Base price of sheet zinc is now 63 $\frac{1}{2}$ c. per lb., f.o.b. La Salle-Peru, Ill., less 8 per cent. discount.

New York Metal Exchange—At the annual meeting, March 29, officers were re-elected as follows: President, P. R. Jennings; vice-president, Morton B. Smith; treasurer, Robert L. Crooke; members of the board of managers, B. Hochschild, H. W. Hendricks, L. Vogelstein, G. E. Behr, Paul Koning, George W. Jacques, Emil Baerwald and A. B. Hall; arbitration committee, J. Langeloth, E. A. Caswell, E. J. Keane, Edwin Groves and H. D. Bond.

Other Metals

Antimony—Business is only of a retail order. Prices are a shade lower, 8c. per lb. being quoted for Cookson's; 7 $\frac{3}{4}$ c. for Hallett's; 7 $\frac{1}{2}$ c. for ordinary brands.

Aluminum—The quotations here are about 22@24c. per lb. for No. 1 ingots; 33@34c. base for sheets.

Quicksilver—New York quotations are unchanged at \$45@46 per flask of 75 lb. San Francisco, \$44@45 for domestic and \$2 less for export orders. London, £8 7s. 6d. per flask, with £8 6s. 3d. quoted by jobbers.

Nickel—Large lots, contract business. 40@45c. per lb. Retail, spot, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. The price for electrolytic is 5c. higher.

Cadmium—Current quotation 75c. per lb., in 100-lb. lots, at Cleveland, Ohio.

Magnesium—Quotations for this metal are \$1.25 per lb., New York, in 100-lb. lots; for 5-lb. lots, \$1.40 per pound.

Zinc and Lead Ore Markets

Year to Mar. 27.....	23,778,354	839,680

In addition to the above there was shipped to the American Zinc Ore Separating Company to a total of 318,000 lb.; to the Joplin Separator Works, 243,600 lb. zinc ore.

The shipment of zinc ore covering the first three months of the year shows an increase of 4270 tons over the corresponding period of last year. The stock now in bins approximates 7000 tons of raw concentrates. About 80 per cent. of this stock will be roasted or separated by the electrostatic method. A number of mills and roasting plants have resumed work within the past two weeks.

Joplin, Mo., March 27—Better than \$41 per ton paid for the very best zinc sulphide ore, purchased on a base of \$38 per ton of 60 per cent. zinc. Heavy sales were made on a base price ranging from \$37 to \$37.50, with a rising market at the

NOTE.—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

week end. Zinc silicate lowered toward the close, practically but one buyer seeking this grade at the week end. The highest reported was \$23, and the base was \$17@19 per ton of 40 per cent. zinc. Average price, all grades, \$35.48. Exciting rumors gained currency today relative to lead-ore prices, and though prices were materially advanced, offerings reaching \$53.50, or \$2 above the previous week, rumors of \$55 could not be verified. The average price, all grades, is \$52.22 per ton.

Another week of abbreviated shipment, with a strong output all over the district, has piled up approximately 8000 tons of reserve stock in the bins, fully 30 per cent. of which is, however, under contract.

Chemicals

New York, March 31—There is a slight strengthening of the chemical market and, although few sales are being made, prices remain practically stationary.

Copper Sulphate—Prices are still \$4.60 per 100 lb. for carload lots and \$4.85 for smaller quantities. Only a moderate amount of trading is noticed.

Arsenic—The general better feeling of the market has kept prices up to 3c. per lb. for white arsenic.

Nitrate of Soda—The market is dull and prices are 2.15 for both spot and futures.

Mining Stocks

New York, March 31—In the early part of the week the general markets continued in the same quiet and irregular condition which has been noted for some time past. Later, however, a strong bull movement set in, which has sent prices up, and at the close the market must be reported active with prices firmer than they have been for some time. In part this seems to be the result of a purely professional movement, but in part also it is due to the underlying conviction of Wall Street that the tone of business is improving and that better conditions may be expected.

There was one sale of Homestake, of South Dakota, during the week, 25 shares changing hands at \$92 per share.

The Curb market has been strong and active. The copper stocks were rather irregular, but the better class advanced under the leadership of Nevada Consolidated, in which there was some heavy transactions, the closing price being above that of last week. In the Nevada gold stocks the principal incident was a flurry in Goldfield Consolidated which sent the price up on the basis of heavy sales. Other Nevada stocks were also firm. The Cobalt stocks were affected by the recent declaration of large dividends by several companies, and closed firm. The present prospect is for a continuance of the bull movement for a time at least.

New York and St. Louis, cents per pound.
London in pounds sterling per long ton.

THE MINING INDEX

The editors of this paper read all the important publications of the world that relate to mining and the treatment of minerals. This index is published as a reference for all interested and to make it impossible for readers of the **ENGINEERING AND MINING JOURNAL** to miss any important article published anywhere.

We will undertake to furnish a copy of any article (if in print) in the original language, for the price quoted. Where no price is quoted the cost is unknown. These papers are not kept in stock, but must be ordered from the publisher; hence there will be some delay for foreign papers.

No accounts can be opened for these small amounts, but remittance must be sent with order. For the convenience of those making small but frequent remittances, coupons are furnished at the following prices: 20 cents each, six for \$1.00, thirty-three for \$5.00 and one hundred for \$15.00. This arrangement will be especially appreciated by foreign readers and men in distant mining camps. Where remittances are made in even dollars we will return the excess over an order in coupons upon request.

ALUMINUM.

8819—**USES**—Aluminum. E. B. Wilson. (Mines and Minerals, Mar., 1909; 1½ pp.) A condensed discussion of the uses, principal sources, methods of extraction from ores, assay processes, and the gems of aluminum. 20c.

AMMONIA AND AMMONIUM SULPHATE.

8820—**BY-PRODUCT AMMONIA**—Traitements des Eaux Ammoniacales des Fours à Coke aux Poudreries Staveley (Grande-Bretagne). (Génie Civil, June 13, 1908; 1 p.) Describes the construction and operation of a plant for saving ammonia from coke ovens at the Staveley Works in England. 40c.

ASBESTOS.

8821—**DEPOSITS**—Depth of Asbestos Deposits. Fritz Cirkel. (Can. Min. Journ., Mar. 1, 1909; 3 pp.) A geological discussion as to the probable depth of asbestos deposits, using the Canadian mines as a basis for argument. Sketches. Paper before the Can. Min. Inst. 20c.

8822—**PREPARATION**—The Technical Preparation of Asbestos. (Bull. Imp. Inst., Vol. VI, No. 4, 1908; 5½ pp.) Describes the details of the various steps in the commercial preparation of asbestos. 40c.

8823—**QUEBEC**—On the Asbestos Deposits of the Eastern Townships of Quebec. John A. Dresser. (Econ. Geol., Mar., 1909; 10 pp.) Treats of the geology of the region and the character and origin of the veins. Illustrated. 60c.

8824—**ASBESTOS**. (Indust. Maz., Feb. 1909; 7 pp.) Brief general notes on asbestos occurrence in Canada and its industrial uses. 20c.

BAUXITE.

8825—**HUNGARY**—Neue Ostungarische Bauxitkörper und Bauxitbildung Ueberhaupt. Richard Lachmann. (Zell. f. prakt. Geol., Sept., 1908; 10½ pp.) Describes the nature and occurrence of a number of bauxite deposits in eastern Hungary, and discusses carefully a theory of their origin. 40c.

BORAX.

8826—**ITALY**—La Industria de ácido Bórico en Toscana. Angel Funari. (Geologia y Minas, July and Aug., 1908; 10 pp.) Describes the occurrence of natural borate fields in Tuscany, and the methods of collecting and preparing it. 40c.

CEMENT

8827—**CANADA**—The Cement Industry in Canada. (Can. Engr., Feb. 26, 1909; ½ p.) A historical review of the industry, with statistics. 20c.

COAL AND COKE.

8828—**ACCIDENTS**—Prevention of Mine Explosions. James Ashworth. (Mines and Minerals, Feb., 1909; 1 p.) Review of the report by foreign experts who visited the United States upon the invitation of the Government. Illustrated. 20c.

8829—**ACCIDENTS**—Recent Mine Dis-

asters—Cause and Remedies. J. S. Cunningham. (Black Diamond, Feb. 13, 1909; 1½ pp.) Discusses conditions in the bituminous regions of America with especial reference to cause and remedies for recent mine disasters. Paper before the Am. Min. Congress. 20c.

8830—**BRIQUETS** and Their Effect on Market Values of Coal. Matthew Ferguson. (Black Diamond, Feb. 27, 1909; 1½ pp.) A discussion of the economic features of the manufacture of briquets. Illustrated. 20c.

8831—**BRIQUETTING**—Coal Briquetting. C. T. Malcomson. (Mines and Minerals, Mar. 1909; 3½ pp.) Describes the plant at Hartsborne, Okla., and outlines the process of making briquets from slack. Illustrated. 20c.

8832—**CALORIFIC POWER**—Determination of the Calorific Power of Coals. (Aus. Min. and Eng. Rev., Jan. 5, 1909; 4 pp.) Details of the processes used for this determination. Illustrated. 40c.

8833—**CANADA**—The Coal Fields of Alberta. D. B. Dowling. (Econ. Geol., Jan.-Feb., 1909; 11 pp.) Discussion of the occurrences and estimation of the content of the coalfields of Alberta. Map. 60c.

8834—**COAL DUST EXPLOSIONS**—Les Expériences Anglaises sur les Pous-sières de Houille. Leprince-Ringuet. (Ann. des Mines, Tome XIV, 8 Livr., 1908; 28 pp.) Results and conclusions of a long series of experiments on the explosibility of dusty atmosphere, conducted at Alforts, England.

8835—**COAL WASHING**—Ernest Coal-Washing Plant. (Mines and Minerals, Jan.-Feb., 1909; 1½ pp.) Describes additions and improvements made to the plant since May, 1904. Illustrated. 20c.

8836—**COKE**—Étude sur la Fabrication du Coke la récolte et le traitement de sous-produits de la distillation de la houille. Adrien Say. (Bull. Société de l'Industrie Minérale, Jan., 1909; 22 pp.) A serial article treating exhaustively of the subject of coke making. The first chapter describes some special kinds of regenerative, by-product ovens, etc.

8837—**COKE OVEN**—An Elongated Coke Oven. W. R. Elliott. (Mines and Minerals, Mar., 1909; 2½ pp.) Details the method of coking by which coke is charged into ovens on trains of cars and hauled out when coked. Illustrated. 20c.

8838—**COLLIERY WATER**—Note on a Deposit of Sulphur in a Colliery Water. G. H. Stanley. (Trans. N. Eng. Inst. Min. and Mechan. Eng., Jan., 1909; ¼ pp.) Gives result of analysis of colliery water and discussion of the same.

8839—**COLORADO**—The Delagua Mines. F. W. Whiteside. (Mines and Minerals, Feb., 1909; 2 pp.) Description of the Delagua mines of the Victor Fuel Company of Denver, Colo., pointing out the adaptation of surface arrangements to suit peculiar topography and location of mine openings. Illustrated. 20c.

8840—**COLORADO AND UTAH**—Reconnaissance of the Book Cliffs Coal Field Between Grand River, Colo., and Sunnyside, Utah. G. B. Richardson. (Bull. 371. U. S. Geol. Surv., 1909; 54 pp.) Set forth the stratigraphy, structure and the occurrence of the coal with a general statement of its nature. Illustrations and colored map.

8841—**CONSTITUENTS OF COAL**—The Amount of Inert Volatile Matter in the Mineral Constituents of Coal. W. Brinsmaid. (Journ. Ind. and Eng. Chem., Feb. 1909; 2½ pp.) Discussion on coal analysis with especial reference to determining true amount of ash. 60c.

8842—**DRILLING**—Jottings on Boring. W. S. Gresley. (Journ. Brit. Fed. Soc. Min. Students, Feb., 1909; 15 pp.) A summary of observations collected during 30 years' experience in connection with collieries and other mines. Gives many uses of core drills and data of their use.

8843—**ELECTRIC HOISTS** as Adapted for Coal Mines. R. H. Rowland. (Eng. and Min. Journ., Feb. 27, 1909; 3 pp.) Enumerates the advantages of electric winding and compares in detail the most improved equalizing systems. Illustrated with line drawings. 20c.

8844—**EXPLOSION**—Lick Branch Disaster. H. H. Stock. (Mines and Minerals, Mar., 1909; 6 pp.) Describes the mine, giving plans, and tells of the reports of the mining inspectors who investigated after the two explosions. Illustrated. 20c.

8845—**EXPLOSIONS**—Isolation of Certain Areas after an Explosion. Nell Robinson. (Mines and Minerals, Mar., 1909; ¾ p.) Describes the installation of automatically closing doors, designed to confine after-gases created by explosions. Plan. 20c.

8846—**FIRST AID**—Organization of First-Aid Corps. M. J. Shields. (Mines and Minerals, Mar., 1909; 1½ pp.) History of the movement in Europe and America. Methods of instruction used in anthracite region of Pennsylvania. 20c.

8847—**FIRST AID MOVEMENT**. The H. H. Stock. (Mines and Minerals, Jan. 1909; 5½ pp.) History and description of the methods and organizations of the different companies in the anthracite region. Illustrated. 20c.

8848—**HAULAGE**—Self-Acting Carriage Inclines. William Loudon. (Min. Eng., Mar., 1909; 1½ pp.) Describes a system of incline superior in many ways to the chain or the jig-brow systems of running coal down to the main level. Illustrated. 20c.

8849—**HAULAGE**—The Mosgrove Incline. William L. Affelder. (Mines and Minerals, Jan., 1909; 1½ pp.) An illustrated description of method of construction used to avoid common defects, and other results derived. 20c.

8850—**HAULAGE AND PUMPING**—Estimate for Electrical Mine Haulage and Pumping Scheme. E. H. W. Westwood. (Inst. Min. and Eng. Rev., Feb. 5, 1909; 1½ pp.) Notes dealing with the case of an installation of electric haulage and pumping system in a coal mine. Details will serve as the basis for greater installations. 40c.

8851—**ILLINOIS**—Coal Deposits and Oil Field Near Duquoin, Ill. J. Udden. (Min. Jour., Mar. 13, 1909; 2½ pp.) A geological discussion of the district with statistics on the coal production. 20c.

8852—**INDIA**—The Coal Mining Industry in Bengal. Glen George. (Eng. and Min. Journ., Mar. 13, 1909; 3½ pp.) Discusses the labor conditions and methods of operation in the Bengal coal fields. Illustrations and map. 20c.

8853—JAPAN. Ueber den heiligen Stand des Bergbaus in Japan. Bruno Simmerschlag. *Indust. Zeit.* 1. B. II. u. S. Band 56, Heft 5, 1908; 8½ pp. An article translated from an official Japanese publication describing in some detail the mining industries of Japan, with special reference to coal.

8854—LIGNITE COAL MINING in Bohemia. William C. Hall. (*Mines and Minerals*, Jan., 1909; 2½ pp.) Details methods employed in working thick pitching seams in Bohemia, describes plant and discusses labor costs. Illustrated. 20c.

8855—LITERATURE.—A Digest of Recent Coal Literature. Floyd W. Parsons. (*Eng. and Min. Journ.*, Mar. 6, 1909; 5 pp.) Summarizes the suggestions of great value and discussions of important questions by engineers in papers read at the mining meetings held during the winter. Illustrated. 20c.

8856—MINING METHOD.—Notes on Working Thick Coal. Lawrence Holland. (*Coll. & Guard.*, Feb. 13, 1909; 1½ pp.) Describes the methods in vogue at the Hamstead Colliery. Extracts of two papers read before the So. Staffordshire and Warwickshire Inst. of Min. Engineers. 40c.

8857—MINING METHOD.—Underground Coal Conveyors. C. Gaunt. (*Min. Eng. and Min. Journ.*, 1909; 3 pp.) Describes the system for working a particular coal deposit, giving all details of operation, with sketches. 20c.

8858—MONTANA.—The Great Falls Coalfield. E. B. Black. (*Eng. and Min. Journ.*, Mar. 20, 1909; 3½ pp.) This article gives a historical résumé of the operations on the Great Falls coalfield, especially at the Anaconda Copper Mining Company's Belt mine. Map and illustrations. 20c.

8859—OKLAHOMA Coal Fields. C. N. Gould. (*Mines and Minerals*, Jan., 1909; 1½ pp.) Gives geology and location, estimates of value, and conditions of ownership of the fields. 20c.

8860—PEAT and the Production of Power. Herbert Philipp. (*Electrochem. and Met. Ind.*, March, 1909; 2 pp.) Discussion of the adaptability of peat as a fuel for power plants. Methods of use. Paper read before the Am. Peat Soc., Feb. 13, 1909. 40c.

8861—PENNSYLVANIA.—The Jenner Mine of the Somerset Coal Co. J. L. Wagner. (*Mines and Minerals*, Feb., 1909; 1½ pp.) Describes the extensive application of modern electrical appliances, systems of transmission and application of power by electricity at the Jenner mine. Illustrated. 20c.

8862—PERU.—Informe Preliminar Sobre el Yacimiento Carbonifero de Huayday Provincia de Otuzco-Departamento de Libertad. Ernesto Du B. Lukis. (*Bolet. del Cuerpo de Ingenieros de Minas del Perú*, No. 61, 1908; 62 pp.) Describes the occurrence of coal at Huayday. Department of La Libertad, Peru, and proposes a method of developing it.

8863—PULVERIZED FUEL.—The Use of Pulverized Fuel for Heating Industrial Furnaces. I. K. Mende. (*Chem. Engr.*, Feb., 1909; 5 pp.) Paper before the Am. Inst. Chem. Engr., giving details of the use of pulverized coal as a fuel. Illustrated. 40c.

8864—SAMPLING.—Accuracy in Sampling Coal. E. G. Balloy. (*Journ. Ind. and Eng. Chem.*, Mar., 1909; 1½ pp.) Mathematical discussion based upon the theory of probabilities, setting forth experiments and results obtained from them. Charts. 60c.

8865—SCREENING PLANT.—Colliery Coal Tre. Rev. Feb. 5, 1909; 5 pp.) Describes and discusses details of colliery screening plants. Illustrated. Paper before the Nat. Assn. of Coal Managers. 40c.

8866—SIBERIA.—Die Kohlenwerkstätten und Schächte in Westsibirien. P. Thiers. (*Indust. Zeit.* 1. B. II. u. S. Band 56, Heft 5, 1908; 4 pp.) Outlines the condition of the coal mining industry in the vicinity of Tomsk and Tobolsk.

8867—STORAGE OF COAL.—Die Lagerung von Steinkohle unter Wasser und die Methode der Abfuhr dieses Verfahrens. Kurt Seidl. (*Gleichenk.*, Jan. 16 and 23, 1909; 13½ pp.) Discusses the storage of bituminous coal under water with re-

sults of practical tests on coal thus handled. 60c.

8868—TESTING.—Washing and Coking Tests of Coal at the Fuel-Testing Plant, Denver, Colo., July 1, 1907, to June 30, 1908. A. W. Belden. (*Eng. and Min. Journ.*, Mar. 6, 1909; 8 pp.) Details of washing and coking tests performed with more than 100 varieties of coals. A detailed report of the results of the tests is given for each sample treated. Illustrated. 40c.

8869—VENTILATION.—Problems of Mine Ventilation. Gas Caps of Inflammable Gas. (*Iron and Coal Tr. Rev.*, Feb. 12, 1909; 2½ pp.) Report of lecture by W. H. Hepplewhite, H. H. Inspector of Mines, with charts and illustrations. 40c.

8870—WEST VIRGINIA.—Coal Fields of West Virginia. H. H. Stoeck. (*Mines and Minerals*, Jan. and Feb., 1909; 8 pp.) Illustrated description of the geology, transportation facilities, and composition of the coals. Continuation of article previously indexed. 40c.

8871—WEST VIRGINIA.—Department of Mines Bulletin, Vol. 1, No. 1. (*Dept. Mines, Va. No.*, 1908; 29 pp.) Details of investigations of mine accidents.

8872—WYOMING.—Coal Mining in Wyoming. E. B. Black. (*Aust. Min. and Eng. Rev.*, Feb. 5, 1909; 5 pp.) A general description of the section with description of plants and particulars of the location of the principal mines. Illustrated. 40c.

COPPER.

8873—ARIZONA.—The Copper Creek Mining District. Ariz. Tr. Roy Sibley. (*Min. Wld.*, Mar. 13, 1909; 1½ pp.) Describes the geology, promising copper series in the district of the Bunker Hill region, and the concentrating mill of the Copper Creek Mining Company. Illustrated. 20c.

8874—BLAST FURNACE GASES.—Power from Copper Blast Furnace Gases. Robert Schorr. (*Eng. and Min. Journ.*, Feb. 27, 1909; 1½ pp.) Describes the furnace operations at Mansfeld, Germany, by which furnace gases yield power equivalent to 7.4 horsepower per ton of ore treated. Tables. 20c.

8875—BLAST FURNACE PRACTICE.—The Corrosion of Water Jackets of Copper Blast Furnaces. (Bull. A. I. M. E., Feb., 1909; 10 pp.) A discussion of the paper of G. R. Allen, describing experiments with various remedies to prevent corrosion. 40c.

8876—CALIFORNIA.—The Balakala Consolidated Copper Company. (*Eng. and Min. Journ.*, Mar. 6, 1909; 3½ pp.) A comprehensive statement of general conditions and summaries of the mine, surface and aerial tramway operations during 1908. Illustrated. 20c.

8877—LEACHING PROCESS.—Eigenschaften Kupfererzgewinnungs-Verfahren. O. Brühl. (*Elektrochem. Zeit.*, Nov. 1908; 6½ pp.) Discusses the practicability of the method of leaching copper ores with a ferrous chloride solution, and describes an apparatus designed for applying this method. 40c.

8878—MEXICO.—Prospection pour Cuivre au Sud de l'Etat de Michoacan. (Mexico). R. V. Ricard. (*Bull. des Ingenieurs Civils de France*, May, 1908; 31 pp.) Notes of a prospecting tour through the State, with special reference to occurrences of copper ore.

8879—MILL.—Description of the Lloyd Copper Company's Concentrating Mill at Butte, N. S. W. (*Eng. and Min. Journ.*, Dec. 11, 1907; 5½ pp.) Describes details of treatment and gives flow sheet.

8880—ORE OCCURRENCE.—The Localization of Values in Ore Bodies and the Occurrence of Chutes in Metalliferous Deposits. C. L. Taylor. (*Geol. Trans.*, 1909; 15 pp.) Presents some comments on a specimen hauler from the Calumet and Hecla conglomerate. Discusses the distribution of copper in the Lake Superior copper belt. 60c.

8881—PERU.—Informe Anual Sobre la Labor de la Comision del Cerro de Pasco durante el Año 1907. (*Bolet. del Cuerpo de Ingenieros de Minas del Perú*, No. 61, 1908; 67 pp.) A description of the equipment and operation of the Cerro de

Pasco's Tinchahuaco smelter, including the coal washer, coking plant, power station, etc.

8882—QUEENSLAND.—The Mining Industry in Queensland. G. W. Williams. (*Eng. and Min. Journ.*, Mar. 20, 1909; 3½ pp.) First of a series of articles. Deals with the conditions on the Chillies copper fields, describing the chief mines and smelting methods. Line drawings. 20c.

8883—REFINERY.—The Electrolytic Refining and Smelting Company of Australasia, Ltd. S. N. Bell. (*Aust. Min. and Eng. Rev.*, Jan. 1909; 4 pp.) An illustrated description of the refining works erected recently at Port Kembla. N. S. W. Illustrated. 40c.

8884—SAMPLING AND ASSAYING the Copper Ores of the Ely District. Robert Marsh, Jr. (*Sch. Min. Journ.*, Jan., 1909; 7 pp.) Sketches how properties were sampled with churn drills, and outlines assay methods and details. 60c.

8885—SMELTER.—The Fink Smelter. W. C. Ebaugh. (*Journ. Ind. and Eng. Chem.*, Mar., 1909; 2½ pp.) Gives a description of the smelter of the Boston Consolidated Company at Garfield, Utah. Discusses the new process. Illustrated. 60c.

8886—SMELTER.—The Granby Smelter. R. Koffer. (*Min. and Sci. Press*, Feb. 13, 1909; 2½ pp.) Describes the largest copper plant in Canada, giving complete scheme of treatment. Illustrated. 20c.

8887—SMELTER FUMES.—Some Experiments with the Ferric Oxide Contact Method of Making Sulphuric Acid from Smelter Fumes. T. W. Smith. (*Chem. Engr.*, Feb., 1909; 2 pp.) Explains experiments which led to the erection of the large chamber plant at Ducktown by the Ducktown Sulphur, Copper and Iron Company. 40c.

8888—SMELTING PLANT.—An Up-to-Date Description of the Smelting Plant. Charles C. Christensen. (*Min. Wld.*, Feb. 27, 1909; 2½ pp.) A detailed description of plant with specifications. Illustrated. 20c.

8889—UTAH.—The Ohio Copper Company, Bingham, Utah. J. MacFarlane. (*Min. Wld.*, Feb. 20, 1909; 3½ pp.) Discussion of region as a copper producer, and particularly of Ohio property. Describes an occurrence of copper ore in quartzite. Illustrated. 20c.

GOLD AND SILVER.

8890—ARIZONA.—Operation and Production of the Congress Mines. S. F. Shaw. (*Min. Wld.*, Feb. 27, 1909; 1 p.) Description of mining operations and milling system. Illustrated. 20c.

8891—ASSAYING.—Routine Assaying of a Westralian Mine. W. B. Rlyth. (*Journ. Chem. Met. and Min. Soc. of So. Africa*, Dec., 1908; 3½ pp.) A description in detail of the routine assaying work at one of Westralia's 100-stamp free milling propositions. 60c.

8892—CALIFORNIA.—Milling at Grass Valley and Nevada City. G. E. Welcott. (*Eng. and Min. Journ.*, Feb. 27, 1909; 2½ pp.) Describes the details of amalgamation, concentration and treatment of mill concentrates. Also outlines the treatment of concentrates. Illustrated. 20c.

8893—COLORADO.—The Alice Mine. R. L. Herlick. (*Mines and Minerals*, Feb., 1909; 3 pp.) Discussion of the economic conditions at the Alice mine. Describes the largest orebody situated in the Fall River district. Illustrated. 20c.

8894—COSTS.—Working Costs on the Rand. W. F. Wilkinson. (*Eng. and Min. Journ.*, Mar. 13, 1909; 1 p.) Interesting data relating to the treatment of the ore of the Rand, showing the reduction that has been made, and its effect on the grade of ore. 20c.

8895—CRUSHING PLANT.—The Knight Central Starts Crushing. (So. African Min. Journ., Feb. 6, 1909; 1½ pp.) Describes the new plant and in particular several of its novel features. The plant will comprise 300 stamps weighing 1750 lbs. each, and 6 tube mills. Illustrated. 20c.

8896—CYANIDATION.—Methods of a Cyanide Clean-up. Generally Adopted on the Kalkville Plant. F. O. McArdle. (*Proc. Sydney Univ. Edg. Soc.*, Mar. 10, 1907; 6½ pp.) Gives a general idea of

the methods usually adopted in the cyanide "clean-up" at the principal mines of the district. Discusses the subject as divided into seven different stages.

8897—CYANIDATION—Precipitation from Cyanide Solutions by Zinc Shavings and Dust: A Comparison of Results and Costs. Allen, C. Clark. (Journ. Chem., Met. and Min. Soc. of So. Africa, Jan., 1909; 1½ pp.) A summary of the results obtained from comparing the zinc shavings and zinc dust precipitation methods in the same plant. 20c.

8898—CYANIDE MILL—The Standard Consolidated Cyanide Mill, S. F. Shav. (Eng. and Min. Journ., Mar. 6, 1909; 2 pp.) Describes the details of the milling practice at Bodie, Cal., where the pulp after being crushed and cyanidized and passed over amalgamation plates, is treated by mechanical agitation tanks and Morse rollers. Illustrated. 20c.

8899—DREDGING for Gold and Tin. (Aust. Min. Stand., Jan. 6, 1909; 1½ pp.) An abstract from the booklet published by Messrs. Thompson and Company, Castlemaine (Vic.), on dredging plants, dealing with sluices and flumes and giving some notes on gaging streams. 40c.

8900—DREDGING—Gold Dredging in New Zealand During the Year 1908. (N. Z. Mines Rec., Jan. 16, 1909; 3 pp.) Summarizes the operations during 1908 in Otago and Southland, giving gold yield and particulars of some of the public companies. 40c.

8901—DREDGING—Gold Dredging. J. N. Vanhus. (Am. J. Eng., Jan. 20, 1909; 1½ pp.) Description of operation at Oroville and Folsom and of the dredges employed in the work. Illustrated. 20c.

8902—ELECTROLYTIC REFINING—Apparatus for Electrolytic Refining of Precious Metals. H. Lacroix. (Electrochem. and Met. Ind., March, 1909; 2 pp.) Detailed description of apparatus used in several important processes. Illustrated. 40c.

8903—FILTER PRESSING—Treatment of the Gold and Silver Precipitate at Dos Estrellas. Walter Neal. (Min. and Sci. Press, Feb. 27, 1909; 1 p.) Gives the reason for discontinuing the practice of briquetting the precipitate, and shows advantages of the present method of treatment. 20c.

8904—FINE GRINDING—Grading Assays and Grinding Efficiencies. Arthur Yates. (Journ. Chem., Met. and Min. Soc. of So. Africa, Dec. 1908; 3½ pp.) Treats of the value of detailed analyses in connection with estimating the crushing efficiency and relative merit of machines, and also as a method for checking extraction results. 60c.

8905—GEOLOGY—The Origin of the Gold of the Colorado. Gen. W. Gregory. (Econ. Geol., Mar. 1909; 11 pp.) A geological discussion of the genesis of the Rand "banket" or gold-bearing conglomerate. Summarizes the theories which have been advanced. 60c.

8906—HYDRAULIC ENGINEERING in the Yukon. R. W. Hagarty. (Can. Eng., Feb. 19, 1909; 5½ pp.) Detailed discussion of hydraulic and hydroelectric installation of Yukon Gold Company and information upon engineering conditions peculiar to the Yukon. Illustrated. 20c.

8907—HYDRAULIC MINE—Sucre de Bolivia Hydraulic Mine. G. E. R. Wallace. (Min. and Sci. Press, Feb. 20, 1909; 1½ pp.) Describes and gives conditions at the largest auriferous gravel bank known in South America. Illustrated. 20c.

8908—IDAHO—Central Idaho Gold Districts—VI. S. P. Jellum. (Northwest Min. News, Feb. 1909; 5½ pp.) Describes geography, topography and geology and sets forth conditions of the Pierce City mining district in Idaho. Illustrated. 20c.

8909—IDAHO—Coeur d'Alene Mining District, Idaho—VIII. J. P. Rowe. (Min. Wld., Feb. 20, 1909; 1½ pp.) Discussion of the gold and silver deposits of the northside district northwest with short descriptions of a number of promising prospects. Considers also tungsten deposits of the region.

8910—IDAHO—The Coeur d'Alene Mining District, Idaho—XI. J. P. Rowe. (Min. Wld., Mar. 6, 1909; 2½ pp.) Concludes the series of articles dealing with this mining district. Sums up and explains why certain mining methods are

resorted to. Map showing all mining claims of the district. 20c.

8911—MEXICO—Santa Barbara Mine. (Mines and Minerals, Mar. 1909; 1½ pp.) Describes the mine and mill methods by which a large body of rich silver ore is treated. Illustrated. 20c.

8912—MILL—The Goldfield Consolidated Mill, Goldfield, Nevada. A. H. Martin. (Min. Sci., Feb. 11, 1909; 1½ pp.) Description of the methods employed at the largest and latest plant in the Goldfield district. Illustrated. 20c.

8913—NEVADA—Glory-Hole Mining at DeLamar, Nevada. W. R. Wardner. (Eng. and Min. Journ., Feb. 27, 1909; 2 pp.) Describes the method of mining by which the total cost of extraction is less than 3½c. per ton. Illustrated. 20c.

8914—NEVADA—Mining Conditions in the Goldfield District, Nevada. A. H. Martin. (Min. Wld., Mar. 13, 1909; 3½ pp.) Treats of the general conditions of the district, and describes in detail the new Goldfield Consolidated and Florence mills, the Nevada Goldfield reduction works and the Goldfield Cl. chlorination plant. Illustrated. 20c.

8915—NEVADA—The Mines and Mills of Tonopah, Nevada. G. E. Wolcott. (Eng. and Min. Journ., Feb. 20, 1909; 3 pp.) Describes the milling practice and details of the Belmont, Montana-Tonopah and Desert mills. Illustrations and flow sheets. 20c.

8916—NEW MEXICO—Genesis of the Lake Valley, New Mexico, Silver Deposits. (Bull. A. I. M. E., Feb. 1909; 6 pp.) Discussion of the paper by Chas. R. Keyes, recounting the unique history of mining in this region and showing Mr. Daly's connection with the properties. 40c.

8917—RE-WASHING at Cripple Creek, S. A. Worcester. (Min. and Sci. Press, Feb. 20, 1909; 2 pp.) Description of the methods in vogue at the chief mines in the district. 20c.

8918—OREGON—Some Mining Operations in Eastern Oregon. (Min. Wld., Mar. 13, 1909; 2 pp.) Describes conditions and the various operations in the Blue Mountains to the West and North of Baker. Illustrated. 20c.

8919—PEARCE GOLD-SEPARATION PROCESS. H. V. Pearce. (Bull. A. I. M. E., Feb. 1909; 12½ pp.) History and description of the gold and silver refining system employed formerly at the Boston & Colorado Smelting Company, Argo, Colo. 40c.

8920—PLACER GOLD MINING in Interior Alaska. (Eng. and Min. Journ., Mar. 13, 1909; 3 pp.) Discusses the field for prospecting in the Fairbanks, Tanana and Koyukuk districts. 20c.

8921—PLACER MINING—A Rocker. Douglas Waterman. (Min. and Sci. Press, Feb. 20, 1909; ¾ p.) Gives specifications for portable rocker to be used in testing placer-ground. Describes operation. 20c.

8922—SAMPLING—Observations on Sampling in the Rand and Rhodesian Mines. H. F. Loftis. (Min. Journ., Feb. 20, 1909; ¾ p.) Additions to the data upon the subject taken from personal observation. 40c.

8923—SMELTING—Battery and Cyanide Gold Smelting. A. Thomas. (Journ. Chem., Met. and Min. Soc. of So. Africa, Dec. 1908; 2 pp.) Reply to a discussion criticising the paper on the above subject. Brings out some interesting and instructive details of the work. 60c.

8924—SMELTING AND SAMPLING of Gold Bullion on the Great Boulder Mine. Alex. Fraser. (Monthly Journ. W. A. Chamber of Mines, Dec. 31, 1908; 5 pp.) Gives details of the practice of smelting and refining bulk charges of bullion and pouring into bars therefrom. Illustrated. 80c.

8925—SOUTH AFRICA—Gold Near Lake Albert. (So. African Min. Journ., Feb. 13, 1909; 1½ pp.) A résumé of the government geologist's report, giving useful information on the district, and a discussion of 'tanga as a gold producer. 20c.

8926—STOPING—"Shrinkage" Stopping in Western Australia. F. P. Rolfe. (Bull. Inst. of Min. and Met., Feb. 11, 1909; 10 pp.) Description of the method of stoping used at the Lake View Consols Gold Mine, discussing advantages and disadvantages of the system. Illustrated.

8927—TRANSVAAL ORE DEPOSITS—Interesting Study of the Transvaal Ore Deposits. E. J. Richter. (Min. Wld., Mar. 13, 1909; 1½ pp.) A geological discussion treating the petrography of the quartz reefs. Sketches. 20c.

8928—VICTORIA—The Southern End of the Bendigo Goldfield. D. Clark. (Aust. Min. Stand., Jan. 1 and 20, 1909; 3 pp.) Discusses opportunities for further important work in the region, and gives plan showing lines of reef on Southern end of field. Describes the Golden Fleeced, Herbel's and Langdon mines. 60c.

8929—WASHINGTON—Orient District, Washington. L. K. Armstrong. (Northwest Min. News, Feb. 1909; 7½ pp.) General description of the Orient mining district, Stevens county, with a separate treatment of each of the main properties of the district. Illustrated. 20c.

8930—WESTERN AUSTRALIA—Report on the Kanowna Mines. A. Montgomery. (West Aust. Dept. of Mines, July, 1908; 77 pp.) Report of present prospects and state of progress of the Kanowna mines, giving map, plans and statistical tables. 60c.

8931—WESTERN AUSTRALIA—Report on the Mines of the Kilgarn Goldfield. A. Montgomery. (West Aust. Dept. of Mines, Sept., 1908; 64 pp.) A report of the general impressions received on a rapid tour around the various mines, with reports on treatment tests and table of production. 60c.

GYPSUM.

8932—ITALY—Die Gipse des toskanischen Erzgebirges und ihr Ursprung. E. Lotli. (Zeit. f. prakt. Geol., Sept., 1908; 5 pp.) Describes the occurrence of gypsum at a number of localities in Tuscany, and discusses their origin. 40c.

IRON AND STEEL.

8933—BASIC STEEL PLANT—Das neue Thomas-Stahlwerk der Durbacher Hütte. P. Schroeder. (Stahl u. Eisen, Nov. 11, 1908; 30 pp.) Describes in great detail the equipment and operation of this modern German plant. 40c.

8934—BLAST FURNACE GAS BLOW-ING ENGINE. (Engineer, Feb. 5, 1909; 1½ pp.) Description of the Nurnberg engine constructed by the Lillshals Company and installed at the Barrow Hematite Iron and Steel Company's Works. Detailed drawings and illustrations are included. 40c.

8935—BLAST FURNACE PLANT—Einige neuere Beförderungsanlagen auf Hochofenwerken. (Stahl u. Eisen, Dec. 2, 1908; 9 pp.) Describes a new German plant for smelting iron ores which contains all the latest improvements in the way of appliances. 40c.

8936—BRIQUETTING—Mittellungen über Einige neuere schwedische Anlagen und Verfahren für Aufbereitung und Bricketierung von Eisenerzen und Kiesabfällen. G. Franke. (Glückauf, Oct. 3 and 10, 1908; 18 pp.) Describes the equipment and operation of a Swedish plant at Flogherget for briquetting iron ore and pyrite cinder, describing machinery, the process, and giving costs. 60c.

8937—BRIQUETTING—The Grondal Method of Briquetting Ore. N. V. Hansell. (Iron Tr. Rev., Feb. 18, 1909; 5 pp.) A description of a process largely employed on European iron ores, and statements of the results obtained. Illustrated. 20c.

8938—CARBON IN IRON—Vereinfachter Apparat zur Bestimmung des Kohlenstoffes in Eisen. Theo. Grzeschke. (Chem.-Zeit., Nov. 7, 1908; 1 p.) Describes an ingenious and very compact apparatus for determining carbon in iron. 20c.

8939—CARBON IN STEEL—A Nickel Crucible for the Determination of Carbon in Steel. H. E. K. Ruppel. (Journ. Ind. and Eng. Chem., Mar. 1909; 3 pp.) Ind. and Eng. Chem., Mar. 1909; 3 pp.) Description of an apparatus designed to supplement the work of the shimer crucible in the regular laboratory work. Elevation and plan. 60c.

8940—CONSTITUTION OF STEEL—The Mysteries of Metals. J. C. Arnold. (Engineering, Feb. 5, 1909; 3½ pp.) A lecture delivered at the Royal Institu-

tion discussing the constitution of steel. Contains tables and twenty sections. 40c.

8941—CORROSION of Iron. (Eng. Rec., Feb. 20, 1909, 1½ pp.) Describes chemistry of corrosion of iron and suggests remedies for same. Abstract of paper by W. H. Walker before the Boston Society of Arts. 20c.

8942—CORROSION of Iron and Steel. A. Sang. (Proc. Eng. Soc. W. Penn., Jan., 1909, 6 pp.) A detailed discussion of this phenomenon with a discussion of the paper by other members of the Society. 40c.

8943—ELECTRIC POWER—Electric Main Drives in German Mills.—I. Eugene Elchel. (Iron Tr. Rev., Mar. 4, 1909; 8 pp.) A discussion of the features attending the development of the electric drive. This section treats of the generating end. Illustrated. To be continued. 20c.

8944—ELECTRIC POWER—The Industrial Application of the Electric Motor, as Illustrated in the Gary Plant of the Indiana Steel Company. B. K. Shover. (Proc. Am. Inst. Elec. Engrs., Mar., 1909, 60 pp.) Sets forth the industrial application of electricity and the motive power in steel mills. With illustrations and charts. 60c.

8945—ELECTRIC SMELTING—Deoxidation and Desulfurization in Electric Steel Furnaces. R. Amberg. (Electrochem. and Met., Jan., 1909, 1½ pp.) Explanation on the basis of well-known principles, the discrepancies of electric steel refining from the older metallurgical practice. 40c.

8946—ELECTRIC SMELTING—Notes on Iron and Steel. Bradley Stoughton. (Journ. Franklin Institute, Feb., 1909; 15 pp.) The electrothermic manufacture of iron and steel, and the properties and uses of alloy steels. Illustrated. 60c.

8947—FOUNDRY—Steel Foundry Shrinkage Problems. It. A. Bull. (Iron Tr. Rev., Feb. 25, 1909; 2½ pp.) A comprehensive discussion of the causes of shrinkage and the methods of overcoming this difficulty. 20c.

8948—FRENCH IRON INDUSTRY—L'Industrie Métallurgique dans le Bassin de la Loire. A. Vicarie. (Société de l'Industrie Minérale, Jan., 1909; 16 pp.) Describes the equipment and processes of a number of French iron and steel works, some of which illustrate the most modern and improved systems.

8949—HARDENED STEEL—Zur Frage über die Struktur des gehärteten Stahles. J. Kurbatov. (Metallurgie, Dec. 22, 1908; 10 pp.) A microscopic study of the structure and composition of hardened steel. 40c.

8950—HARDENING AND TEMPERING—Electric Annealing Furnaces for Hardening and Tempering High-class Tools. B. C. Kiser. (Elec. Wld., Feb. 18, 1909; 2½ pp.) Sets forth the advantages, other than of cost, of electric heating for furnaces. Describes three types of furnaces. Illustrated. 20c.

8951—HIGH SPEED STEEL—The Manufacture of High-Speed Steel. O. Becker. (Cassier's Mag., Feb., 1909; 16 pp.) Treats of the practical use of high speed steel, dealing particularly with the methods of manufacture. Illustrated. 40c.

8952—IRON-PHOSPHOR-CARBON—Weitere Untersuchungen über das Ternäre System Eisen-Phosphor-Kohlenstoff. P. Goerens and W. Döbelsch. (Metallurgie, Oct. 8, 1908; 9 pp.) Notes and results of a microscopic study of alloys of these three elements. 40c.

8953—LAKE SUPERIOR—The Great Iron Fields of the Lake Superior District. R. B. Brinsmade. (Min. Sci., Feb. 18 and 25, 1909, 4 pp.) Eighth and ninth of a series of papers dealing especially with conditions and methods as found on the Gogebic Range, Mich. 40c.

8954—MAGNETITE ORE—Eisenglanz und seine Verarbeitung im Eichtelgebirge. Albert Schmidt. (Zeit. f. prakt. Geol., Sept., 1908, 7½ pp.) Outlines the geology of the district, discusses the occurrence and origin of the magnetite ores, and describes the methods of working at some of the mines. 40c.

8955—MALLEABLE CASTINGS—Production of Malleable Castings. N. J. Reid and Moldenke. (Foundry, Mar., 1909; 4 pp.) Discusses the construction and operation of annealing furnaces and

methods of charging and discharging the annealing pots. Illustrated. 20c.

8956—MINING METHODS—Open-Pit Iron Mining on the Mesabi Range. J. Fred Wolff. (Mines and Minerals, Feb. and Mar., 1909; 10 pp.) System of excavation, methods of mining, and equipment used on the Mesabi range in Northern Minnesota. Illustrated. 40c.

8957—NICKEL IN STEEL—Eine neue direkte Bestimmungsmethode des Nickels im Stahl. H. Grossmann and W. Heitborn. (Stahl u. Eisen, Jan. 27, 1909, 1½ pp.) Describes a process involving a special reagent, dicyandiamidn sulphate, for determining nickel gravimetrically. 40c.

8958—OIL HEATING FURNACE and Steam Hammer Foundation at the New Plant of the Western Iron Works, Seattle. (Iron Tr. Rev., Feb. 18, 1909, 1½ pp.) Describes and gives detailed drawings of the oil heating furnace and shows how an adequate foundation for steam hammer was secured on a tidal mud flat. Illustrated. 20c.

8959—ONTARIO—The Iron and Steel Industry of Ontario. G. C. Mackenzie. (Bureau of Mines, Vol. XVII, 1908; 152 pp.) A historical and statistical review of the industry, discussion of the iron ores, and description of plants and methods of Ontario, with illustrations and maps.

8960—ONTARIO—Iron Ranges East of Lake Nipigon.—I. A. R. Coleman. (Bureau of Mines, Vol. XVII, 1908; 35 pp.) Gives the results of two summers' work on the geology of this region. Illustrated.

8961—ORE DRESSING—The Grondal Method of Concentrating Ore. N. V. Hansell. (Iron Tr. Rev., Feb. 11, 1909; 2½ pp.) A description of the wet magnetic methods and apparatus now extensively employed in Sweden, and in other European countries for concentrating iron ore. Illustrated. 20c.

8962—ORE DRESSING—Ueber Hand-scheidung und mechanische Aufbereitung des Rotsteinsteins im Dillenburgischen Eickhof. (Stahl u. Eisen, Jan. 29, 1909; 4½ pp.) Outlines the method of dressing iron ores at this locality, and gives details of operation, including costs. 40c.

8963—PIG-IRONS and Their Use. E. Adamson. (Iron and Coal Tr. Rev., Feb. 26, 1909; 1½ pp.) Classifies the various pig-irons and discusses the effects of various constituents. 40c.

8964—ROLLING MILLS—Power Requirements in Rolling Steel. (Iron Rev., Mar. 11, 1909; 5½ pp.) This paper gives the results of the investigations of a special German commission. Treats of the power requirements of the passes with due consideration of the temperature and mechanical qualities. Illustrated. 20c.

8965—STEEL MIXING—Die zukünftige Entwicklung des Mischers und des Herd-Fischprozesses. A. E. Pratt. (Metallurgie, Nov. 22, 1908; 7 pp.) Advances several methods by which the mixing process can be widened in its application to the steel-making industry. 40c.

8966—TITANIUM—Effect of Titanium Alloy on Steel. Charles V. Slocum. (Iron Tr. Rev., Feb. 25, 1909; 2½ pp.) Discusses the effects of the alloy in various types of steel. Illustrated. 20c.

8967—TITANIUM—The Use of Titanium in Steel for Rails, Car Wheels, Etc. Charles V. Slocum. (Electrochem. and Met., Jan. 2, 1909; 2½ pp.) Discusses the effects of the use of titanium in the manufacture of steel. Illustrated. 40c.

8968—TUNGSTEN and CHROMIUM IN STEEL—Die Bestimmung von Wolfram, Chrom und Silizium im Chromwolframstahl. S. Zinberg. (Stahl u. Eisen, Dec. 9, 1908; 1 p.) A method for determining tungsten, chromium and silicon in special steels containing them. 40c.

8969—WASTE HEAT—The Utilization of Waste Heat in Iron Works. J. R. Kershaw. (Iron Tr. Rev., Feb. 18, 1909, 1½ pp.) Shows that a market exists for electric power generated from coke oven and blast furnace gases. Discussion of the electric furnace for the making of structural and special steel. 20c.

8970—BRITISH COLUMBIA—Lead Mining in British Columbia During Past

Year. (B. C. Min. Exch., Feb., 1909; 3 pp.) A complete summary of the progress of the industry during 1908, with statistics. Illustrated. 20c.

8971—OZARK LEAD- AND ZINC-DEPOSITS. Their Genesis, Localization, and Migration. C. R. Keyes. (Bull. A. I. M. E., Feb., 1909, 45 pp.) Notes suggestive of some practical solutions of the problem of devising a scheme whereby the productive ore belts may be located with greater certainty. Illustrated.

MANGANESE.

8972—ANALYSIS—Ueber die oxydometrisch Bestimmung des Mangans mit Kaliumferri-cyanid. H. Bollenbach and E. Luchmann. (Chem. Zeit., Nov. 11 and 14, 1908; 3 pp.) Discusses and describes a method for determining manganese by titration with potassium ferrocyanide, and gives comparative results. 40c.

8973—GEORGIA—The Manganese Ore-Deposits of Georgia. Thomas L. Watson. (Econ. Geol., Jan. Feb., 1909; 10 pp.) Summarizes the principal facts pertaining to the manganese deposits in Georgia. Gives geology of deposits and chemical composition of the ores. 60c.

MINERAL PAINTS.

8974—GEORGIA—The Mining and Treatment of Ocher in Georgia. S. Mays Ball. (Min. Wld., Mar. 6, 1909; 1½ pp.) Describes conditions of the Cartersville belt, and outlines the treatment schemes at the various plants. Illustrated. 20c.

PETROLEUM.

8975—FIRE—The Roma Bore. (Queens. Gov. Min. Journ., Jan. 15, 1909; 2½ pp.) Describes sinking of bore and how the fire was extinguished. Illustrated. 60c.

8976—GEOLOGY—A Sketch of the Geology of the Baku and European Oil-Fields. L. V. Dalton. (Econ. Geol., Mar., 1909; 28 pp.) A short general account and description of the districts of Caucasus, Roumania and Galicia. Illustrations and maps. 60c.

8977—GEOLOGY—Studies in the Application of the Anticline Theory of Oil and Gas Accumulation. Malcolm J. Munn. (Econ. Geol., Mar., 1909; 16 pp.) Describes the structural and stratigraphic position of certain oil pools in the Stickley Quadrangle, Penn. of the U. S. G. S. Illustrated. 60c.

8978—PUMPING—Tests Upon Compressed Air Pumping Systems of Oil Wells. E. M. Ivens. (Journ. A. S. M. E. Mar., 1909; 19 pp.) A description of the systems and the results of experiments made with them at Evangeline in the Louisiana oil fields. Illustrated.

8979—ROMANIAN PETROLEUM PRODUCTION During 1908. (Petrol. Rev., Feb. 27, 1909; 2 pp.) Complete statistics and full details in tabular form of the production of crude oil. 40c.

8980—RUSSIAN PETROLEUM INDUSTRY. (Petrol. Rev., Feb. 13, 1909; 14 pp.) A ten years' brief retrospect of the famous Baku oil fields. Gives table of production. 40c.

PHOSPHATE ROCK.

8981—FLORIDA—L'Exploitation des Phosphates de Floride. (Génie Civil, Nov. 21, 1908; 4 pp.) Discusses the commercial aspects of the phosphate industry in the South, and describes a typical plant for cleaning pebble phosphate. 40c.

8982—FLORIDA—Mining and Milling Florida Phosphate. (Econ. Geol. and Min. Journ., Mar. 6, 1909; 2½ pp.) Gives all the details of the mining and milling operations of the largest plants in Florida. Illustration and line drawings. 40c.

8983—TUNIS—Cenni Sui Giacimenti di Fosfato dell'Aggeria e della Tunisia. O. Piotti. (Ministero di Agricoltura, Industria e Commercio, Rome, 1908; 43 pp.) An exhaustive description of the geology and occurrence of phosphate deposits in northern Africa, the methods of operating them, and the outlook for the industry.

PLATINUM.

8984—RUSSIA—Russlands Platinanhand und produktion. (Eisen-Zeit., Feb.

LEAD.

27, 1909; ¾ p.) Statistical treatment of the commercial value and production of platinum in Russia. 20c.

PRECIOUS STONES.

8985—DIAMONDS and Their Bearing Upon the Future of Brazil. (Bull. Internat. Rep. Am. Republics, Feb. 1909; 27 pp.) Describes operations in South Africa and Brazil, and treats economic features of the industry as pertaining to the future of Brazil. Illustrated. 20c.

8986—DIAMONDS—The Copeton Diamonds, New South Wales. A. R. Pike. (Aust. Min. Stand., Jan. 27, 1909; 1½ pp.) First paper of series; treats the characteristics of the matrix and the alluvial deposits. Sketches. 40c.

QUICKSILVER.

8987—ANALYSIS—Ueber die massanalytische Bestimmung des Quecksilbers nach rhodan-alkalischen, jodometrischem und acidimetrischem Verfahren. E. Rupp. (Chem.-Zeit., Nov. 4, 1908; 2¼ pp.) Discusses and describes three volumetric methods for determining mercury. 20c.

RARE METALS.

8988—ZWISTEN—Die Zechsteinformation zwischen dem Diemel- und Riter-Tale am Ostrande des rheinisch-westfälischen Schiefergebirges unter besonderer Berücksichtigung, Cölestin und Schwespat-Vorkommen. Kipper, Glück-auf, Aug. 8, 1908; 12½ pp.) Describes the occurrence of celestite at Obergembeck, in Rhinish Westphalia, the methods of mining and preparing it for market, and record measurements on a great variety of crystals. 40c.

8989—THORIUM—The Specific Radio-Activity of Thorium and its Products. G. C. Ashman. (Am. Journ. Sci., Jan., 1909; 8 pp.) Gives the results of recent investigations. 60c.

8990—URANIUM—The Speed of Oxidation by Air, of Uranium Solutions. A Note on the Volumetric Determination of Uranium. H. N. McCoy and H. H. Bunzel. (Journ. Am. Chem. Soc., Mar., 1909; 6 pp.) Disposes of the difficulties of the volumetric determination of uranium, and gives results of experiments on oxidation. 80c.

8991—VANADIUM—A Critical Discussion of the Analytical Methods of Estimating Vanadium. W. F. Bleeker. (W. Chem. and Min. Feb., 1909; 9 pp.) Discussion of the principal methods proposed for the determination of this metal. 80c.

8992—VANADIUM—The Rare Metals—IX. Charles Easkerville. (Eng. and Min. Journ., Mar. 6, 1909; ½ p.) Gives a list of vanadium minerals, and discusses their occurrence in various localities. 20c.

8993—ZIRCONIUM—The Rare Metals—X. Chas. Easkerville. (Eng. and Min. Journ., Mar. 13, 1909; ½ p.) Gives a list of zirconium minerals and discusses their occurrence and uses. 20c.

SALT.

8994—LOUISIANA AND TEXAS—The Geological Occurrence of Rock Salt in Louisiana and East Texas. G. D. Harris. (Econ. Geol., Jan.-Feb., 1909; 25 pp.) A geological discussion with maps and illustrations. 60c.

SLATE.

8995—WALES—Welsh Slate and the Penryn-Quarry. C. P. Fisher. (Geol. Surv. Min. Journ., Jan. 15, 1909; 2½ pp.) A general report on the location and operation of the quarry. Illustrated. 60c.

SULPHUR.

8996—UNALASKA—Makushin Sulphur Deposits, Unalaska. N. O. Lawton. (Min. and Sci. Press, Feb. 13, 1909; 2 pp.) Descriptive of Unalaska, giving results of investigation of the rumored inexhaustible sulphur deposits. Illustrated. 20c.

TIN.

8997—ALLUVIAL DEPOSITS—Recovery of Tin from Alluvial Deposits. H. G. Trenchard. (Aust. Min. Stand., Jan.

13, 1909; 1½ pp.) Notes on the stream sluicing plants at Ringha, N. S. W., for recovering tin from the abandoned workings and leads too poor for hand treatment. 40c.

8998—DETINNING—Die Entzinnung des unbrauchbaren und ihre wirtschaftliche Bedeutung. K. Goldschmidt. (Stahl u. Eisen, Dec. 30, 1908; 7 pp.) Describes methods and plant for removing tin from scrap plate. 40c.

8999—DETINNING OR TINPLATE SCRAP—Its Economic Importance. K. Goldschmidt. (Min. Journ., Feb. 20, 1909; ½ p.) Economic discussion of the industry and description of methods. Illustrated. 40c.

9000—QUEENSLAND—The Dolcoath. L. C. Ball. (Queensland Gov. Min. Journ., Feb. 19, 1909; 3 pp.) Describes one of the largest and oldest tin mines in the world, treating of the conditions under which it is worked and the methods employed. Illustrated. First of a series of articles. 60c.

9001—SOUTH AFRICA—Zaaiplaats Tin Mines. (So. African Min. Journ., Feb. 13, 1909; 1 p.) Describes the plant and workings, going into the geology of the deposits. Illustrated. 20c.

TUNGSTEN.

9002—WOLFRAM ORES—Occurrences and Uses. C. Bogenrieder. (Aust. Min. Stand., Dec. 30, 1908; 2 pp.) Continuation of article previously indexed.

ZINC.

9003—ELECTROLYTIC RECOVERY—Elektrolytische Zinkgewinnung. Walther Stöger. (Oest. Zeit. f. B. u. H., Jan. 2, 1909; 4 pp.) Describes latest process in the electrolytic recovery of zinc. 40c.

9004—ELMORE VACUUM PROCESS at Broken Hill, New South Wales. Stanley Elmore. (Min. Journ., Feb. 20, 1909; 2½ pp.) Description of the metallurgical installation with description of the process in the electrolytic and flow sheets. 40c.

9005—OZARK LEAD-AND ZINC-DEPOSITS: Their Genesis, Localization and Migration. C. R. Keyes. (Bull. A. I. M. E., Feb., 1909; 45 pp.) See under "Lead."

ECONOMIC GEOLOGY—GENERAL.

9006—CANADA—Geology of Thunder Bay—Algoma Boundary. Arthur L. Parsons. (Bureau of Mines, Vol. XVII, 1908; 41 pp.) A complete geological description of the region with 13 sketches indicating formations encountered.

9007—DIP AND PITCH. (Bull. A. I. M. E., Feb., 1909; 12½ pp.) A continuation of the discussion brought about by a paper upon the subject by Dr. R. W. Raymond. 40c.

9008—LODYRITE from Tonopah, Nevada, and Broken Hill, New South Wales. E. H. Kraus and C. W. Cook. (Am. Journ. Sci., Mar., 1909; 13 pp.) A mineralogical discussion of lodysite found in silver ores. Illustrated. 60c.

9009—MINERAL WATERS—Erschließung der Mineralgebiete der Erforschung der Mineralquellen. R. Dalkes-kamp. (Zeit. f. prakt. Geol., Oct., 1908; 43 pp.) An exhaustive discussion of the occurrence and origin of mineral springs. Their origin, classification, and the methods of controlling and utilizing their waters, and their physiological and curative properties. 40c.

9010—MONTANA—Geology and Water Resources of the Great Falls Region. Mont. Geol. and Water Survey. Paper 221. U. S. Geol. Surv., 1909; 89 pp.) Study of geology and water resources with especial reference to possible utilization of the latter. Illustrations and maps. 60c.

9011—ORE DEPOSITS—A Theory of Volcanic Action and Ore Deposits, Their Nature and Cause. H. W. Hixon. (Bull. 53, Inst. of Min. and Met., Feb. 11, 1909; 6 pp.) Discusses chiefly the theory to explain volcanic action. The recent earthquake of Messina referred to.

9012—ORE FORMATIONS—A Method for Demonstrating Ore Formation. F. C. Nicholas. (Min. Wid., Feb. 20, 1909; 1½ pp.) Geological discussion of properties of the Cranke and Gold Mining Company in British Columbia, showing ore formations were demonstrated by transparent models. Illustrated. 20c.

9013—ORE OCCURRENCE—Distribution of Metals and Minerals in Ore Shoofs. Gordon Surr. (Min. Wid., Feb. 27, 1909; 1½ pp.) Geological discussion giving examples of many of the important ore occurrences in the world. 20c.

9014—ORE OCCURRENCE—Ores in Volcanic Craters and Fumarole Orifices. Arthur Lakes. (Min. Wid., Mar. 6, 1909; 2½ pp.) A geological discussion giving numerous examples of occurrences as proofs of theories advanced. Illustrated with sketches. 20c.

9015—ORE OCCURRENCE—The Localization of Values in Oreodies and the Occurrence of Shoofs in Metalliferous Deposits. W. Lindgren. (Econ. Geol., Jan.-Feb., 1909; 9 pp.) Discussion of recent papers on the subject, setting forth conclusions reached. 60c.

9016—ORE OCCURRENCE—The Many Varied Occurrences of Ore in Veins. A. Lakes. (Min. Sci., Feb. 21, 1909; 1½ pp.) A geological discussion of vein occurrences of ore with sketches of various types of veins. 20c.

9017—ORE OCCURRENCE—Why are Mining Camps Centers of Mineralization. A. Lakes. (Min. Sci., Feb. 13, 1909; 1½ pp.) Continuation of article previously indexed, in which the various terms of ore occurrence in different sections are compared and correlated. 60c.

9018—PERU—Estado Actual de la Minería en Morococha-Informe Anual de la Comisión de Ingen. Alberto Jochanowitz. (Bol. del Cuerpo de Ingenieros de Minas del Peru, No. 60, 1908; 65 pp.) Describes the geology, mineral resources and mining development of the Morococha district of Peru.

9019—PERU—Recursos Minerales del Departamento de Apurimac. A. Jochanowitz. (Bol. del Cuerpo de Ingenieros de Minas del Peru, No. 58, 1908; 99 pp.) Outlines the geology and mineral occurrences in parts of the provinces of Arequipa, Ayacucho, and Ayacucho.

9020—PERU—Económica Minera de las provincias de Tarma, Angaraes y Huancavelica. E. I. Duenas. (Bol. del Cuerpo de Ingenieros de Minas del Peru, No. 62, 1908; 197 pp.) Careful description of the geology and mineral resources of these portions of Peru.

MINING—GENERAL.

9021—ACCIDENTS During Use of Explosives. J. W. Stark. (Mining and Metallurgy, Mar. 1909; 2 pp.) Gives proper methods of storing and transporting explosives, of preparing charges, and loading and firing. 20c.

9022—ALGERIA AND TUNIS—Mineral-vorkommen in Alger und Tunis. Bruno Simmerbach. (Econ. Geol., B. H. u. E., Band 56, Heft 5, 1908; 10 pp.) Enumerates in some detail the various iron, copper, lead and zinc mining operations in Northern Africa.

9023—AUSTRALIA—Mineral and Mining Plant in Australia. (Min. Journ., Feb. 20, 1909; 1½ pp.) Statement of the localities in which are found the chief metals and a review of their developments, describing the more modern machinery used. 40c.

9024—BLASTING—The Gases Resulting from the Use of High Explosives. W. Cullen. (Journ. Chem. Met. and Min. Soc. of So. Africa, Jan., 1909; 2½ pp.) A discussion of paper previously indexed, bringing out some original data upon this subject. 60c.

9025—BLASTING—The Theory of Blasting With High Explosives. E. M. Weston. (Journ. Chem. Met. and Min. Soc. of So. Africa, Dec., 1908 and Jan., 1909; 14 pp.) Discussion of paper previously indexed. Calls attention to certain practical considerations, the neglect of which prevent improvements in the use of high explosives. Illustrations. 80c.

9026—CANADA—The Mineral Production of Canada, 1908. J. McLeish. (Eng. and Min. Journ., Mar. 13, 1909; 3 pp.) A statistical report on the mineral production of Canada, with comments. 20c.

9027—COMPRESSED AIR—The Flow of Compressed Air in Pipes, with Special Reference to Mining on the Rand. E. J. Laschinger. (Journ. Trans. Inst. of Mech. Eng., Jan., 1909; 9 pp.) Author's reply to discussion. Gives formulae and

tables on coefficient of friction for air flowing in pipes, with discussion of general complicated air conditions. 60c.

9028—CONCRETE—In Mine Support. W. L. Crane. (Eng. and Sci. Press, Feb. 27, 1909; 5 pp.) Gives examples where concrete was used to advantage in mine support, and discusses the conditions of the various cases. Illustrated. 20c.

9029—DIAMOND DRILLING—Note on Diamond Drilling. Clarence M. Haight. (Sch. Mines Quart., Jan., 1909; 2 pp.) Tells how a broken bit was recovered from diamond drill holes at Rockland, Mich. Illustrated. 60c.

9030—DRILLING—Practical Points for Operating the Banka Drill. J. Chisholm. (Min. Journ., Feb. 20, 1909; 1½ pp.) Sets forth mining conditions in British Guiana with many hints for operation of a 6-inch Banka drill. Illustrated. 40c.

9031—DRILLS—Sharpening of Drills Underground. Rheinel. (Journ. of the South African Assn. of Eng., Jan., 1909; 5 pp.) A discussion by the members of the Association on the advisability of sharpening drills underground. 60c.

9032—DRILLS—Ways of Improving Piston and Hammer Drills. E. M. Weston. (Eng. and Min. Journ., Mar. 13, 1909; 4 pp.) Discusses the factors tending for efficiency in piston drills and gives suggestions for improving it. Describes the Konomax automatic piston drill. Illustrated. 20c.

9033—EXPLOSIVES—Emploi des Explosifs dans les Mines de houille de Belgique pendant l'année 1907. Victor Watteyne and Adolphe Breyer. (Extract from Ann. des Mines de Belgique, XLI, 1908; 51 pp.) Statistics of consumption of different kinds of explosives, the compositions of which are also stated, classified according to the nature of the mining work done throughout Belgium during 1907.

9034—EXPLOSIVES—Versuche mit Sicherheitsprengstoffen. Beyling. (Glückauf, Dec. 5, 1908 and Jan. 23, 1909; 10 pp.) Results of tests on explosives, of various compositions, found supposed to be safe in gassy mines. 60c.

9035—FINGER-CHUTE. Charles A. Chase. (Min. and Sci. Press, Feb. 27, 1909; 1½ pp.) A description of the modified finger-chute gate at the Liberty Bell mine, Telluride, Colo., with side and front elevation. 20c.

9036—FINGER-CHUTE—Mining in the Harz. (Engineering, Feb. 12, 1909; 1 p.) Historical review of mining in the Harz and description of present conditions. 40c.

9037—HOISTING—Eine neue Sicherheitsvorrichtung für Dampfördermaschinen. G. Schönfeld. (Glückauf, Jan. 1909; 4 pp.) Discusses the mechanics of hoisting by screws and describes a new appliance to prevent overwinding. 40c.

9038—HOISTWAY—Reclaiming the Inclined Hoistway at Mine 21. Guy C. Stoltz. (Eng. and Min. Journ., Mar. 20, 1909; 1½ pp.) Describes how the mine of the Port Henry Iron Ore Company was opened up through the debris in an open pit. Illustrated. 20c.

9039—KOREA—Mining in Korea. Consular Report. (Min. Sci., Feb. 11 and 18, 1909; 5 pp.) Review of the latent mineral resources of Korea and the progress already made in their development, with especial reference to the effect upon American interests. 40c.

9040—LABOR—White Labor in Mining. Tom Johnson. (Journ. Chem. Met. and Min. Soc. of So. Africa, Jan., 1909; 4½ pp.) Compares the costs and results obtained in South Africa with white, Chinese and native labor. 60c.

9041—LEASING—A Proposed Basis of Settlement in Mine Leasing. William H. Davis. (West. Chem. and Met., Feb., 1909; 6 pp.) Sets forth conditions for fixing of equitable royalties in mine leasing. 50c.

9042—MECHANICS OF MINING—Maschinenwirtschaft in Bergwerken II. Hoffmann. (Zeit. des Vereines Deutscher Ingenieure, Jan. 2, 1909; 124 pp.) An exhaustive discussion of the several features of mining practice into which machines enter most largely. The first fundamental treats mainly of pumping, especially with centrifugal and turbine pumps.

9043—METAL MINING—Some Unsettled Problems in acid-leaching, zinc leaching. (Quintess. Forest Lecture delivered at Inst. Civil Engis., London, 1908; 38 pp.) Considers the problems connected with the extraction of the ores of the metals from their natural deposits within the earth's crust, and their production in such a form as to enable the metallurgist to deal with them.

9044—MEXICO—Jansco and Colima. W. A. Scott. (Ann. and Sci. Press, Feb. 13, 1909; 1½ pp.) Brief notes on present conditions in this portion of Mexico, mentions the active volcano, Colima. Illustrated. 20c.

9045—MINE ACCOUNTING—II. J. G. Grant. (Can. Min. Journ., Mar. 1, 1909; 1 pp.) A continuation of a series of articles upon this subject. Deals in particular with "stores." To be continued. 20c.

9046—MINE FIRES—La Lutte Contre les feux souterrains. A. Aron. (Ann. des Mines, Tome XLII, 6 livr., 1908; 66 pp.) Describes the usual methods of extinguishing mine fires, and gives details of a number of the most disastrous occurrences of this kind.

9047—MINE WATCHMEN—Electric Recording Apparatus for mine watchmen. C. L. C. Richter. (Eng. and Min. Journ., Feb. 27, 1908; 1 p.) Illustrated description of an electric system used at the Calumet & Hecla mine for recording the movements of watchmen. 20c.

9048—MINING LAW—Short Talks on Mining Law—XIII. A. H. Ricketts. (Eng. and Min. Journ., Mar. 20, 1909; 5 pp.) A digest of the laws governing the securing of a patent for land with a discussion of the proceedings to be followed. 20c.

9049—NEW MEXICO—Luna County, New Mexico. E. McCormick. (Min. and Sci. Press, Feb. 27, 1909; 1 p.) Brief notes on the geography, railroad systems, and mining conditions of the region.

9050—NEW ZEALAND—Quartz and Scheelite Mining in Otago. (N. Z. Mines Rec., Jan. 16, 1909; 1 p.) Describes the property of the United Goldfields of New Zealand Company, Ltd., and outlines the mining methods. 40c.

9051—ONTARIO—Statistical Review. Thomas W. Gibson. (Report of Bureau of Mines, Vol. XVII, 1908; 47 pp.) Gives complete statistics on mineral production and the various mines of Ontario up to the end of 1907.

9052—ONTARIO—Mines of Ontario. E. T. Corkill. (Bureau of Mines, Vol. XVII, 1908; 37 pp.) A complete summary and description of the mining operations of the province. Illustrated. Comprehensive maps.

9053—ORE HANDLING—Handling Ore at Copper Queen Mines, Bisbee. Walter Gardner. (Eng. and Min. Journ., Mar. 13, 1909; 2 pp.) Tells how the ore is hauled in cars with automatic couplers, by electric motors, and loaded into railroad cars by belt conveyers. Illustrated. 20c.

9054—PERU—The Mineral Statistics of Peru for 1907. (Min. Journ., Feb. 13, 1909; 3½ pp.) Gives statistics and conditions of the mining industry. Abstracted from Boletín del Gobierno, Ingenieros de Minas del Peru, No. 67, 1908. 40c.

9055—ROPE LUBRICATION—Neuerungen bei der Förderschleife und Spurlatten-Schmierung. O. Döbberstein. (Glückauf, Jan. 2, 1909; 4 pp.) Describes the construction and operation, with costs, of a simple contrivance for oiling hoisting ropes thoroughly. 40c.

9056—SHAFT SINKING—Das Teufen der Pribramser Schächte. Hugo Stefan. (Oest. Zeit. f. B. u. H., Oct. 3, 1908; 5 pp.) Describes in detail the methods employed in sinking this German shaft below the 1100-m level. 40c.

9057—SHAFT SINKING—Sinking a Wet Shaft at Tombstone. Elton W. Walker. (Min. and Sci. Press, Feb. 20, 1909; 2½ pp.) Tells how one of the encountered in shaft sinking was dealt with. Illustrated. 20c.

9058—SHAFT SINKING—Vertical Shaft Sinking. Buckets vs. Skips. Charles B. Sauer. (Journ. So. African Assn., Engng., Oct. 1908; 10 pp.) Gives details of shaft sinking on the Rand. 80c.

9059—SIBERIA—Mining in Siberia. C. W. Purlington. (Min. and Sci. Press,

Feb. 13, 1909; 1½ pp.) A description of conditions in Siberian goldfields, considering the placer and quartz occurrences of gold, and also some copper and platinum deposits. 20c.

9060—SOUTH AFRICAN MINING INDUSTRY in 1908—IV. (So. African min. Journ., Jan. 23, 1909; 1½ pp.) Statistical review of the years work in Rhodesia. Reviews development of mines and exploitations for base metals and diamonds. 20c.

9061—SURVEYING—A Novel Stadia Rod. J. H. Granberry. (Eng. and Min. Journ., Feb. 27, 1909; ¾ p.) Describes and gives drawing of a stadia rod without figures. 20c.

9062—TIMBER—Strength of Timber vs. Reinforced Concrete. Ernest McCulloch. (Min. Wld., Mar. 6, 1909; 1½ pp.) A theoretical discussion giving formulae and examples of their use. 20c.

9063—TIMBER—The Relation of Non-pressure Processes of Wood Preservation to Pressure Processes. W. F. Shreve. (Eng. News, Mar. 4, 1909; 2½ pp.) A discussion dealing with the history of the development of wood preserving processes. Illustrated. 20c.

9064—TIMBER—Wood Preservation by the "Kyan" Process. R. Hartmann. (Eng. News, Dec. 31, 1908; 3 pp.) Describes and gives details of a method for the prevention of the decay of wood. Illustrated. 20c.

9065—TIMBERING—Square Set Timbering with Round Timber and Greenwood. (Aust. Min. Stand., Jan. 13, 1909; 1 p.) Describes method for the adoption in square set timbering districts where only short and crooked log timber is obtainable. Illustrated by plans. 40c.

9066—TROPICS—Suggestions for the Conduct of Engineering Work in the Tropics. Robert Burgess. (Eng. News, Mar. 11, 1909; 5 pp.) A discussion of conditions in the Latin-American countries. Takes up in order, the requirements, how to get them and how to care for them, methods and equipment, and general suggestions in regard to relations with the natives. 20c.

9067—UNDERGROUND SURVEYING. H. T. Gardo. (Proc. Sydney Univ. Eng. Soc., July 10, 1907; 7 pp.) Gives general résumé of underground surveying methods.

9068—VENTILATION—Benefits of an Auxiliary Fan. H. M. McAlarney and W. H. Kuper. (Mines and Miners, Mar. 1909; 1 p.) Tells of the conditions of a ventilating difficulty encountered, and how immediate relief was obtained. 20c.

9069—VENTILATION—Pressure Fans vs. Exhaust Fans. A. H. Stow. (Eng. A. I. M. E. Feb. 1909; 14½ p.) Discussion of mine ventilation, favoring the use of pressure fans from their effect upon dust. 40c.

9070—WAGES OF MINERS and Engine Drivers in the Leonora, Laverton, and Mt. Morgans Districts. (Monthly Journ. W. A. Chamber of Mines, Jan. 31, 1909; 9 pp.) Gives the awards fixing the wages payable to mining employees in the Leonora, Laverton and Mount Morgans districts, determined by the court of arbitration of Western Australia. 40c.

9071—WATER SUPPLY—A Phase of Ground Water Problems in the West. W. C. Mendenhall. (Econ. Geol., Jan.-Feb., 1909; 11 pp.) Discussion of the conditions in the West with reference to the determination of the proper use of the ground waters in alluvial filled basins. 60c.

9072—WESTERN AUSTRALIA—Report of the Northampton Mineral Field. A. Montgomery. (West. Aust. Dept. of Mines, Mar. 1908; 41 pp.) Gives results of inquiries into the present position and prospects of the Northampton district, which of late years has been almost entirely deserted. Gives tables showing all operations in the district.

9073—WIRE ROPE. R. D. Williams. (Indust. Mag. Feb., 1909; 3½ pp.) General notes on the nature of wire rope with formulae for use in hoisting. 20c.

9074—WIRE ROPES—Some Notes on Testing Wire Ropes. B. Hunter. (Queensland Gas Min. Journ., Feb. 15, 1909; 1½ pp.) Gives the results obtained from testing annually about 200 ropes with a schedule on the particulars of the tests. 60c.

ORE DRESSING—GENERAL.

- 9075—BROKEN HILL ORES — Treatment of Broken Hill Ores. W. Poole. (Queens. Gov. Min. Journ., Jan. 15, 1909; 6½ pp.) Gives dry sheets and details of treatment at the various mines. 40c.
- 9076—CLASSIFICATION at El Tirol Mill, Pima County, Arizona. George W. Brown. (Mines and Minerals, Jan. 1909; 1 p.) Summary of the working results obtained with the Richards pulsator classifier and a comparison of classified with screen sized material. 20c.
- 9077—CLASSIFICATION—Close Sizing of Dry Finely Crushed Ores. E. G. Steele. (Eng. and Min. Journ., Mar. 6, 1909; 2½ pp.) Discusses the advantages of the vibromotor as sizer for dry ores and gives the results of tests. Illustrated. 20c.
- 9078—CLASSIFICATION—The Blanc Turbo-Classifier. (Eng. and Min. Journ., Mar. 6, 1909; ¾ p.) Describes the construction and operation of a novel classifier giving data on its capacity, water consumption and thoroughness of separation. Illustrated. 20c.
- 9079—FLOTATION PROCESS—Concentration of Ores by the Flotation Process. Francis W. Sewell. (Mex. Min. Journ., Mar., 1909; 3 pp.) Describes the process as applied to various types of ore, giving some details of the various plants. 20c.
- 9080—JIG—Richards Pulsator Jig and Classifier. Frank E. Shepard. (Eng. and Min. Journ., Mar. 13, 1909; 2½ pp.) Discusses in full a new principle involved in these machines. Gives details of the capacity and practical results obtained. 20c.
- 9081—LAUNDERS—The Carrying Capacity of Launderers. W. C. Browning. (Mines and Minerals, Feb., 1909; 2½ pp.) Sets forth results of experiments with launders of glass, wood and limestone at different grades. Illustrated. 20c.
- 9082—SAMPLING by Machine. John A. Cress. (Eng. and Min. Journ., Mar. 6, 1909; 1½ pp.) Continued discussion of this subject. 20c.
- 9083—SARDINIA—Apparecchi di Preparazione Meccanica Per Minerali in Uso in Sardegna. Ermilio Ferraris. (Iglesias, 1909; 20 pp.) A treatise upon ore dressing considering the generalities of the subject and in particular, the classification, separation and pulverization of ores. Line drawings and tables.

METALLURGY—GENERAL.

- 9084—ALLOYS for Use in the Brass Foundry. J. H. Hart. (Foundry, Mar., 1909; 2 pp.) Discussion of the results obtained by alloying various metals; solder mixtures and file alloys. 20c.
- 9085 — BLAST FURNACE SLAG—Ueber die Konstitution von Hochofenschlacken. M. Theusner. (Metallurgie, Nov. 22, 1908; 23 pp.) An exhaustive study of experiments, including microscopic study, on the composition and structure of various types of slag. 40c.
- 9086—BROKEN HILL ORES — Treatment of Broken Hill Ores. W. Poole. (Queensland Gov. Min. Journ., Feb. 15, 1909; 4½ pp.) A description of metallurgical processes parallel to the Hunt-Bradford processes which are applied to the Broken Hill lead products. Flow sheets of Port Pirie Smelting Works. To be continued. 40c.
- 9087 — ELECTRIC FURNACE RESEARCHES—Reduction of Refractory Oxides. Production of Ferro-Alloys and Formation of Carbides. (Electrochem. and Met. Ind., Mar., 1909; 4 pp.) Summary of the results obtained in the electric furnace researches carried out at the electro-chemical laboratory of the University of Manchester. 40c.
- 9088 — ELECTRODEPOSITION — The Effect of the Presence of Certain "Addition-Agents" on the Density and Coherence of Electrolytically Deposited Copper, Lead and Silver. Royal F. Taylor and Edward P. Kern. (Sch. Mines Quart., Jan. 1909; 30 pp.) Gives data and conclusions drawn from a series of experiments. Illustrated. 40c.
- 9089 — FURNACE CONSTRUCTION—Shape Brick and Methods of Calculation Requirements for Furnace Work. F. Peters. (Eng. and Min. Journ., Feb.

- 27, 1909; 2½ pp.) Discusses the details of the arrangement of bricks giving dimensions of the various shapes. Illustrated by tables and drawings. 20c.
- 9090 — LABORATORY — A Modern Metallurgical Laboratory. A. M. Portevin. (Am. Machinist, Jan. 21, 1909; 6½ pp.) Details of apparatus used and description of methods employed in the chemical, mechanical and metallurgical departments of De Dion-Bouton Works Laboratory. Illustrated. 20c.
- 9091 — MONEL METAL. David H. Browne. (Electrochem. and Met. Ind., Mar., 1909; 1 p.) Brief description of the physical and chemical properties of this alloy of nickel and copper. 40c.
- 9092—PERU—Informe Sobre la Labor De La Comision de Huarochiri en 1907. Celso Herrera. (Bol. del Cuerpo de Ingenieros de Minas del Peru, No. 68, 1908; 27 pp.) Describes a number of smelting plants at Rio Blanco, Peru.
- 9093—PRODUCER GAS—How to Find the Amount of Moisture in Producer Gas. J. MacFarlane. (Gas Eng. Mag., Feb. 15, 1909; 1½ pp.) Describes the simple rapid method which has given entire satisfaction. Explains the technology of the method. Illustrated. 40c.
- 9094—SAMPLING — A Mathematical View of Sampling, with Reference to the Degree of Accuracy to be Obtained. M. T. Griffin. (Journ. Soc. Chem. Ind., Feb. 27, 1909; 2 pp.) A paper dealing largely with the probability and theory of errors in sampling. This paper treats of sampling in general. 40c.
- 9095—SMELTING AND ITS ABSTRACT. I. H. Sharn. (Proc. Sydney Univ. Eng. Soc., Nov. 13, 1907; 96 pp.) A summary of available information of value connected with the title subject. Discusses particularly the economic combustion of coal as applied to steam boilers. Illustrated. 40c.
- 9096—WELDING—Autogenous Welding with Oxy-Acetylene. Henry Cave. (Am. Machinist, Jan. 28, 1909; 4½ pp.) Describes and discusses the torches used, method of generating the oxygen, and acetylene, and the rules for welding steel, cast iron, brass, etc. 20c.
- 9097—WELDING—Water Decomposition by Direct Current and Alternating Current and Welding with the Oxy-Hydrogen Flame. V. T. Schom. (Electrochem. and Met. Ind., Mar. 1909; 4 pp.) Describes the methods setting forth the dangers of manipulation. Illustrated. 40c.
- 9098—AERIAL ROPEWAYS and Cable-Ways. R. Benedetti. (Eng. Rev. Mar., 1909; 15 pp.) Historical résumé of the advances made in their use with a description of the most important systems. Discusses the details, giving diagrams. Illustrated. 40c.
- 9099—AERIAL TRAM—Die Klemmanparade der Traßelbahnen. A. Plankowski. (Stahl u. Eisen, Nov. 18, 1908; 8½ pp.) Illustrates the several steps in the development of the clamm used for holding the traveling bucket to the drive rope. 40c.
- 9100—BELT CONVEYER. The. (Eng. Rev., Mar. 1909; 7½ pp.) Summarizes the results obtained from a series of experiments performed with a view of determining the effect on the traction driving pulley; the effect of the different arcs of contact on the traction force exerted by the driving pulley; the effect of the different initial tensions of the belts on the tractive force; and the value of rubber covered pulleys as compared to plain ones. Diagrams. 40c.
- 9101—ROLLER FEED WATER—Measuring Boiler Feed Water. W. R. Deere. (Monthly Journ. W. A. Chamber of Mines, Feb. 1, 1909; 2 pp.) A description and sketch of a very simple and accurate apparatus for measuring the boiler feed. 80c.
- 9102 — BOILER FEEDWATER and Its Treatment. I. R. Campbell. (Mines and Minerals, Feb., 1909; 2½ pp.) A discussion of the problem dealing with the impurities contained in water used in the Pittsburgh district. Methods and materials used in treatment. 20c.
- 9103—BOILER TESTS—The Examination of the Cases in Boiler Tests. A. Hunke. (Chem. Engr., Feb., 1909;

- 2½ pp.) Deductions as to the management of the firing operation drawn from data furnished by the Fuel Testing Plant of the U. S. Geological Survey. Diagram of the boiler tests. Paper read before the Am. Inst. Chem. Eng., Dec., 1908. 40c.
- 9104—BOILER WATER — Impurities Causing Scale and Corrosion. J. C. W. Greth. (Power, Mar. 2, 1909; 3 pp.) Discussion of the general characteristics of salts, gases and acids which cause scale or corrosion in boilers; density of water and its purification. 20c.
- 9105—BOILER WATER—Some Useful Lessons of Limestone. Charles S. Palmer. (Power, Feb. 16 and Mar. 2, 1909; 4½ pp.) Interesting experiments in softening temporary and permanent hardness of waters discussed showing the bearing of chemistry upon the subject. 20c.
- 9106—CONVEYERS for the Continuous Handling of Materials. W. N. Twelve-trees. (Eng. Rev., Mar., 1909; 20 pp.) A detailed discussion of the numerous types of machinery designed for transporting materials. Treats the following subjects: fixed trough, moving band and trough, reciprocating trough and bucket conveyers and conveyor driving power, travel and maintenance. Fully illustrated. 40c.
- 9107 — CONVEYERS — Transporters, Elevators and Conveyors. Edward Butler. (Eng. Rev., Mar., 1909; 9 pp.) Discusses the processes involved in the efficient and economical loading and unloading of trucks, barges, and colliery boats, the construction of ships, the conveyance and distribution of coal, manufacturing, power houses, store yards and to gas houses. Illustrated. 40c.
- 9108 — ELECTROLYTIC FURNACE—Gehinnung von Metallen. Welche Leichtmetalle sind als Elektrolyt. (Elektrochem. Zeit., Nov. 1908; 2 pp.) Describes a special kind of furnace for electrolyzing such metals as would float on the current bath, and thus short-circuit the current. 40c.
- 9109—ELECTRIC FURNACE — The Stassano Electric Furnace. F. C. Perkins. (Mines and Minerals, Jan., 1909; 1 p.) Description of an installation of five rotary and fixed furnaces at Turin, Italy. Illustrated. 20c.
- 9110—ELECTRIC POWER—Flywheel Load Equalizer. (Iron and Coal Tr. Rev., Feb. 26, 1909; 2 pp.) Describes the use of the flywheel in connection with an electrical machine as a equalizer of the load on a generating station. Illustrated. 40c.
- 9111—ELECTRIC POWER—Regulating the Use of Electricity in Mines. (Mines and Minerals, Feb., 1909; 1½ pp.) A résumé of recent literature and legislation upon the subject. Low vs. high voltage. 20c.
- 9112—ELECTRIC POWER—The Application of Electricity to Mining. W. E. Dickinson. (Sibley Journ. of Eng., Feb., 1909; 7 pp.) A general discussion treating of the advantages and disadvantages of electricity as a motive power for mines. 40c.
- 9113—ELECTRICAL EQUIPMENT of the Bergport Chemical Works. W. R. Miller. (Elec. Wld., Feb. 25, 1909; 2½ pp.) Discusses two chief features of the works. The size of the installation units and the acid corrosive problems encountered in the atmosphere of the works. Illustrated. 20c.
- 9114—GAS ENGINES — A Graphical Method of Calculating Gas-Engine Efficiencies. E. W. Hollingworth. (Proc. Inst. Civ. Eng., vol. CLXXIII, 1908; 8 pp.) An explanation of the graphic method of calculating the theoretical efficiency of gas engines. Gives formulae and illustrations. 20c.
- 9115—GAS ENGINES—The Use of Large Gas Engines for Generating Electric Power. J. S. Peck and R. Porter. (Iron and Coal Tr. Rev., Feb. 19 and 26, 1909; 4½ pp.) A discussion of the relative costs in generating power by steam turbines and by gas driven generators. Illustrated. Paper before Brit. Instn. of Elec. Eng., Feb. 16, 1909. 40c.
- 9116—GAS POWER—Some Effects of Gas Power on Tendencies and Development of the National Industry in Germany. F. E. Jung. (Iron and Coal Tr. Rev., Feb. 25, 1909; 3½ pp.) Economical study of conditions in Germany. 20c.

CHEMICALS, MINERALS, RARE EARTHS, ETC.—CURRENT WHOLESALE PRICES.

ABRASIVES—			COPPERAS—Bulk 100 lb. \$0 55	POTASSIUM—
Boats, good drill quality, carat.	\$85 00		In bbls. 65¢ @ 75	Bicarbonate crystal. lb. \$ 084 @ .09
Carborundum, f.o.b. Niagara Falls, power. 08			In bags. 60¢ @ .70	Powdered or granulated. lb. .096 @ .094

NOTE These quotations are for ordinary wholesale lots in New York unless otherwise specified, and are generally subject to the usual trade discounts. In the cases of some of the important minerals, such as phosphate rock, pyrites and sulphur in which there are well established markets, the quotations fully represent the latter but in the cases of some of the minor mineral products, the quotations represent what dealers ask of consumers and not what producers can realize in selling their outputs as matters of private contract.

Cost of Pig Iron Made from Lake Superior Ores

Broad General Costs Considered; Operations of Steel Corporation Taken as Representative. Mining Less Expensive Than Transporting the Ore

B Y J. R. F I N L A Y *

The iron ores of the Lake Superior region are the richest in the world, and it is probable that the 400,000,000 tons shipped up to the present time have averaged 60 per cent. in metallic iron per ton of dry ore. Some cargoes have run as high as 68.5 per cent. When you remember that these ores are hematite and that pure hematite is only 70 per cent. iron, you realize that they are exceptionally pure natural concentrates, indeed purer than most artificial concentrates.

When people speak of the output of metal mines in general they mean the gross selling value of the refined metals at New York. Now the value of Lake Superior iron ores is never in mass. You hear of the value of bessemer, or non-bessemer, old range or Mesabi ores at the mines or at Cleveland, but you do not hear of average values nor of gross values in pig iron.

OUTPUT OF VARIOUS MINING DISTRICTS

To get a sense of proportion let us calculate the metal-selling value at New York of the annual output of some of the greatest mining districts for an average of five years: Cripple Creek, gold, \$12,000,000; Transvaal, gold, \$94,800,000; Butte, copper, silver and gold, \$48,000,000; Cœur d'Alene, lead-silver, \$13,000,000; Joplin, zinc and lead, \$16,300,000; Lake Superior, iron, \$290,000,000.

The business is profitable, one of the most profitable in the world, but it is not easy to give precise figures concerning it. Much has been written on the various problems involved, such as the caving system of mining, the systems of accounting, mining in open pits, blast-furnace practice, etc., but each of these is only a link in the chain. I have never found any comprehensive discussion of the subject as a whole. I have, therefore, endeavored to

NOTE.—In this article I have assumed in regard to the United States Steel Corporation that the profits on ore hauled by others will be counterbalanced by profits earned by the corporation on ore hauled for others, so that the final result with regard to this transportation will be the same as if all the ore mined by this company were transported by the company. I have also assumed that the making of pig iron at Pittsburgh is representative in cost, and that pig iron can be made at Pittsburgh and sold at New York for as low a price as pig iron made at other points and shipped to New York. All tons are long tons of 2240 pounds.

*Mining engineer, 2 Rector street, New York City.

work out on an original basis a statement of the cost of operating this vast business. It may be interesting to explain the method.

GENERAL COSTS

The first thing to decide is what to include in the cost. At present, it is not a matter of any particular interest to have details of the mere cost of extracting ore from some particular iron mine and dumping it on the surface, although before the absorption of most of the mines by the various steel and furnace corporations the local mining costs were indeed a subject of interest. There were then many companies which only mined the ore and sold it at the pit mouth.

At the present time by far the greater part of the ore is mined by concerns which use it to make pig iron and in many cases, finished manufactured steel or iron products. To describe this industry in parallel terms to those used in the case of other metals it seems to me that we should find the cost of pig iron delivered at New York. It is quite true that New York is not the greatest market for pig iron, but since I have discussed other metals on the theory of their delivery there it is reasonable to follow the same plan with iron.

The reason for stopping with the production of pig iron is simply the analogy of other metals. Pig iron is the basic commodity of iron manufacture. It bears the same relation to the making of steel rails or pocket knives, as electrolytic-copper bars bear to the making of copper wire or brass door knobs, or as pig lead bears to lead pipe or buck-shot. I have tried to show what it costs to produce from various districts copper, lead and zinc ready for manufacture so I shall try to show the cost of bringing Lake Superior iron to the same stage.

COMPLEXITIES OF THE PROBLEM

When we give this problem some attention we soon find it rather complex. The ore comes from scores of different mines, each producing its own particular grade at its own particular cost. But the cost of getting ore out of the mine is considerably less than that of transporting the ore from the mines to the furnaces, although the cost of transportation varies considerably according to the situation of

the mine. We find that in some cases large royalties are paid to fee owners and in other cases the mining company owns the ground. These various factors are bewildering. Furthermore none of the companies gives its costs.

The United States Steel Corporation, however, issues very good reports. These and various isolated data published by the U. S. Geological Survey and such information as I could get from personal observation are the sources from which my conclusions are derived. The Steel Corporation is fully as much a manufacturing as a mining concern and even buys some of its pig iron from others. It does not stop with pig iron. It makes steel rails, sheets, wire, rods and even spelter and cement. It is the greatest of all industrial enterprises, employing more than 200,000 men. Naturally the reports of such a corporation must be condensed. As a matter of fact no operating data of any kind are given. The omission is in this case quite proper. The production, the earnings, the capital expenditures, the property holdings are all given. This information seems at first insufficient for any definite statement of costs, but it is all that can be had. On two recent trips to the Mesabi range, I saw a good deal of the mines, but I enjoyed no confidences. My inquiries were such as anyone could easily make. I make this explanation in order that no one may be under a misapprehension. The basis for the statements I am about to make is what I believe to be common sense.

ACTIVITIES OF THE UNITED STATES STEEL CORPORATION

The operations of the Steel Corporation are undoubtedly representative of the Lake Superior iron business—far more so than those of any other concern. It mines and ships 55 per cent. of the whole product. It owns two of the three ore railroads in Minnesota and the shipments over its roads are 52 per cent. of the whole Lake Superior output. Just what proportion of the ore is transported on the lakes by the company's boats I do not know. When we come to pig iron we find that the company produces an amount equivalent to 55 per cent. of the probable content of Lake ores. It seems to have about 75 per cent. of the known ore reserves of the region.

MAP SHOWING TRANSPORT OF LAKE SUPERIOR IRON TO SMELTING AND CONSUMING CENTERS

We may conclude, therefore, that this company performs about 55 per cent. of the business all along the line and that its costs would be approximately the same if it did all the business.

One might argue that the costs of the Steel Corporation are radically different in some respects from those of the independents. For instance, an independent may have to pay 80c. a ton for freight that costs the Steel Corporation only 40c. It is for this very reason that the Steel Corporation is most representative. Its business is complete; that of the others, fragmentary. Just as the independents expect a profit on the ore that they own, so they must expect to pay a profit on the transportation that they do not own. It would be next to impossible to work out the real cost of pig iron if we tried to discover and weave together the obscure and disjointed costs and profits of a chain of discordant operators.

CAPITAL EMPLOYED AT IRON MINES

For the purpose of this article the capital employed is one of the most vital elements to consider. Remembering that we are to obtain our costs on pig iron and not on finished products, we must segregate the capital used in manufacturing from that used in mining and smelting. This can be done only approximately. Probably no one could make the division with absolute certainty, for it is necessary to remember that transportation, fuel and power facilities owned by the company are used for the joint purpose of manufacturing steel products and of producing pig iron. I am, therefore, compelled to make a division on my own judgment, and in order to enable the reader to estimate the legitimacy of this judgment, it is necessary to show the method of arriving at it.

The corporation owns in the Lake Superior region 72 iron mines of which 10 are on the Marquette range, 10 on the Menominee, 6 on the Gogebic, 6 on the Vermilion and 40 on the Mesabi range. Neglecting the purchase price of the properties, and considering only the actual money invested in the plants for machinery, development, etc., I make a rough guess that the total capital employed would be somewhat as follows:

Old ranges, each \$2,500,000.....	\$10,000,000
Mesabi range.....	25,000,000
Invested in extensive exploration and developments in the whole Lake Superior region.....	15,000,000
Total investment.....	\$50,000,000

CAPITAL EMPLOYED IN TRANSPORTATION

The Duluth & Iron Range railroad and the Duluth, Missabe & Northern railroad with a total of 363 miles of main line would be indispensable to the conduct of this business, even if it did not extend beyond the production of pig iron. We may calculate the value of this property at \$50,000 to the mile, or in round num-

bers \$18,000,000. The Elgin, Joliet & Eastern railroad and various small lines near the manufacturing plants with a total length of about 295 miles, may be estimated to belong half to the production of pig iron and half to manufacturing. I would charge, therefore, \$7,000,000 in round numbers for these lines. The Bessemer & Lake Erie railroad with 205 miles of lines, I would charge entirely to the production of pig iron, and capitalize it at \$10,000,000. This figures up a total of \$35,000,000 for railroad tracks. In addition to this, we have the railroad equipment which I estimate at \$52,500,000 out of which \$40,000,000 would be necessary for the production of pig iron alone. We have then a total for railroads and their equipment of \$75,000,000.

The marine equipment consists of 76 steamers and 29 barges. Many of these steamers are the largest and best upon the lakes, and some of them undoubtedly cost \$700,000 or \$800,000 each. I should say that the total equipment must be worth \$40,000,000.

CAPITAL EMPLOYED IN COAL AND COKE PROPERTIES

We have in the Connellsville and neighboring regions 62,253 acres of coal lands and 20,471 coke ovens. I believe it would be conservative to estimate the capital employed there at \$30,000,000. In the Pocahontas district there is a lease on 65,497 acres on which are 2151 coke ovens. This property must have cost somewhere in the neighborhood of \$10,000,000 for its development.

There are in addition 31,028 acres of steam-coal ground in Pennsylvania, West Virginia and Ohio. I would estimate the valuation of the plants employed on these properties to be at least \$5,000,000. We have then a total of \$45,000,000 for coal and coke plants. Of this I should say \$35,000,000 would be necessary for the conduct of the pig-iron business of the corporation.

CAPITAL IN BLAST FURNACES

The corporation owns, exclusive of its properties in the South, 100 blast furnaces, many of them the largest and best in the world. This property may be estimated at \$125,000,000.

For the handling and shipping of iron ore, coke and coal, the corporation owns a large number of extensive docks, the total value of which I would guess at \$20,000,000.

CAPITAL IN INVENTORY AND SURPLUS

At the end of 1907, the inventory of stocks and materials used in the business was \$136,000,000, and the surplus in the treasury was \$122,000,000, making a total of \$258,000,000 employed in the current conduct of the company's business. Of this I should say that one-half or approximately \$130,000,000 would be necessary if the company's operations did not go be-

yond the manufacture of pig iron. As a justification of this assumption I may point out that the selling price of pig iron is about half that of steel rails and other heavy finished products which constitute the bulk of the company's sales.

SUMMARY OF CAPITAL USED

We may summarize the capital as follows:

Iron-mine plants and developments	\$50,000,000
Plants for transportation of iron ore.....	115,000,000
Coal, coke and quarry plants.....	35,000,000
Docks and dock equipment.....	20,000,000
Blast furnaces.....	125,000,000
Working capital in inventory and surplus.....	130,000,000
Total.....	\$475,000,000

It is to be noted that this estimate does not include the purchase price of lands or good will, but only such capital as would be required if the opportunity to conduct this business were a free gift. Capital so employed is worth in round numbers 5 per cent. interest, plus a sinking fund calculated to retire the principal in about 40 years. Such a fund is equal to about 1 per cent. additional. We must calculate the use of this capital then at 6 per cent.; and this is not profit. It is merely the actual value of the money employed, such a return as can be secured by an investor without burdening himself with the management of an enterprise. I, therefore, calculate as an operating cost of this business 6 per cent. of \$475,000,000, or \$28,500,000 per year. On an output of 10,000,000 tons of pig iron a year this is \$2.85 per ton.

THE IRON MINES

Let us return to the source of operations and consider what iron-ore resources the company owns. According to the reports of the Minnesota Tax Commission the various properties owned by the Oliver Iron Mining Company on the Mesabi range have in sight 920,000,000 tons. This, I believe, is an estimate only of those ores which are at present merchantable. The large quantities of lower-grade ores on the western portion of the Mesabi range, which depend upon concentration for their utilization, have not, I believe, been reported. The discoveries of this kind of ore are very extensive, and as experiments have gone to the point of demonstrating the practicability of concentrating them, these ores should be considered as a resource. What the total volume of such ores may be I can only guess, but I should say that it would not fall far short of 300,000,000 tons of concentrates, making a total of probable ore on the Mesabi range of 1,220,000,000 tons.

As to the ore resources on the old ranges I have no means of making an estimate. It is to be remembered that these mines extend to great depths and that the exploration of them in advance is not easy, but on the other hand many of them are exceedingly persistent and have already been worked for a great many years with no signs of exhaustion. As-

suming that these mines may be counted on to produce as much in the future as they have in the past, we get an estimate of 114,000,000 tons for the old ranges, that is, outside of the Mesabi range. Therefore, I would estimate in round numbers, the total ore resources of the Steel Corporation in Lake Superior at 1,300,000,000 tons.

It will be seen that I have estimated for the exploration and finding of these ores, outside of cost of mining plants in operation, \$15,000,000. This seems to be an extremely moderate estimate of putting in sight such enormous reserves, but as far as I can judge by the inquiries that I have made the sum is somewhere near the mark. Explorations on the Mesabi range have been extraordinarily fruitful, and the cost for drilling seems to be not much over 1c. per ton developed.

ROYALTIES

A very large proportion of the ores controlled by the Steel Corporation are not held in fee, but under leases on which the company pays a varying rate of royalty. This royalty has shown a constant tendency to increase. Many of the earlier leases provide for a royalty of only 25c. per ton and the leases were made for periods of 20 years or more. In some cases these leases are already near termination and new leases will have to be made at an advanced royalty. Some of the latest leases provide for royalties of 85c. per ton on standard ores with provision for still further increases.

It is probable that under present conditions the company pays an average of not over 20c. per ton, because a good deal of its ores are mined from its own lands, but it is manifestly unfair to the Steel Corporation not to allow for its own land a royalty equal to that which it must pay to other owners. On this basis it is probable that the actual royalty allowable on the ore should be about 40c. per ton.

On the theory that I have adopted for these articles, royalty is not wholly an operating cost, but is in a large part a profit paid to the owners of lands out of their exploitation. Nevertheless, it must be remembered that we have not charged off to capital any of the value of these lands. A certain sum must be allowed to the owners of fees for actual expenditures in holding and developing them, and in the present case it seems more logical to charge off a certain royalty for each ton of iron ore than it is to calculate the actual cost of developing and securing the lands and then to estimate interest and amortization on the total. This latter proposition is absolutely impossible. I believe, therefore, we shall not be far from the mark if we assume a uniform cost of 40c. per ton for royalty, whether the company pays this royalty to other people or pays it to itself.

COST OF ORE FROM VARIOUS RANGES

At present about two-thirds of all the ore from Lake Superior comes from the Mesabi range, but in the case of the Steel Corporation the proportion is over 74 per cent. It is probable that we would not be far wrong if we adopted a proportion of 70 per cent. from the Mesabi range and 30 per cent. from all the others. By making the above division we may make a reasonably close estimate of the cost of mining the Lake Superior ores in general.

On the old ranges the problem is essentially uniform. That is to say, there is no great difference in mining ore on the Menominee range, or on the Vermilion range. In all cases the work is done entirely underground, usually at depths between 500 and 1500 feet. Individual mines, of course, show great variations. In some cases the ore is extremely hard and in other cases extremely soft. Some mines have one large body of soft ore; others have a number of comparatively small bodies of hard ore, but these individual differences occur about equally on all of the ranges.

The cost may be estimated as a function of the output per man per day. In the case of the hard-ore mines, the output per man is as low as 2½ tons per man, while in some of the most favorable soft-ore mines the output exceeds 5 tons per man. Now, the average wages in the Lake Superior region for all men employed may be calculated at \$2.60 per day. We further estimate that wages account for approximately 60 per cent. of the cost at the mines.

It is probable that the actual operating cost may be calculated at the rate of \$4.25 per man employed. On this basis if a mine gets out 2½ tons per man, its operating cost will be \$1.70 per ton; if it gets out 5 tons, its cost will be 85c. I believe the actual figures on the average would fall about half way between these extremes, and that the average output for the old range mines would be somewhere near 3¾ tons per man. This would give a cost of about \$1.15 at the mines, exclusive of taxes.

COSTS ON THE MESABI RANGE

The cost of mining on the Mesabi range is determined almost absolutely by the depth of the surface covering. If the orebody is thin and the overlying surface deep, it is necessary to mine the ore by underground methods. In this case the cost of mining on the Mesabi will be approximately 90c. per ton, the average output per man being 4½ tons.

Open-pit mining varies greatly in cost. This work is now done universally by means of steam shovels and the cost varies according to the proportion of overburden to ore, the texture of the ore, the proportion of boulders and tongues of country rock in the orebody, and the amount of water to be pumped. These

various factors cause abrupt variations in the cost.

We may calculate that the removal of stripping costs 32c. per yard. If one yard of stripping uncovers a yard of ore we will have one yard of ore containing 2½ tons mined at a cost of removing 2 yards of material, or 64c., making the mining cost 25.6c. per ton of ore. To this cost, however, must be added the interest on capital invested in preliminary stripping and other costs of preliminary development of the mine, the cost of pumping and of certain general expenses that do not occur on the ground, so that when equal amounts of stripping and of ore are removed, I calculate that the cost will be decidedly over 30c. per ton. This estimate does not include the cost of taxes which I shall presently discuss separately.

It is evident that the proportion of stripping to the ore does not vary directly according to the relative thickness of the surface and the underlying ore; it is a function of these factors combined with several other factors. The glacial material is usually much more uniform in thickness than the orebodies underneath. The latter are usually trough-shaped with many irregularities at the sides and bottom. Furthermore, pits must have sloping sides so that in cases where the depth of the ore is equal to that of the overburden there will still be a considerably larger volume of overburden removed from the pit than there will be of ore. These considerations induce a good deal of caution on the part of operators in the question of deciding upon open-cut mining where the overburden is deep.

OPEN CUT vs. UNDERGROUND MINING

When the exact proportion of stripping to ore can be worked out, it is a simple question of arithmetic to figure where it will pay to adopt underground mining instead of open pits. As the cost of underground mining is about 90c. per ton, when open-pit operations are cheaper than that, theoretically the mining should be done by the latter method. But in practice we find that a good many practical considerations come in to interfere with carrying this method to its logical limits. Among these may be pointed out the necessity of investing a large amount of money in excavating the overburden before mining can be undertaken. In the case of companies that are financially weak this is a matter of considerable importance.

In many cases where open-pit mining would have been much cheaper, the ore has been mined underground because the mine could be opened more rapidly and a certain profit more quickly realized even though the operators knew that they were not securing the best costs. This argument does not apply to the Steel Corporation, of which the capital is abundant for undertaking operations in the most comprehensive way. As a matter of fact, it is in many cases resorting to open-pit

methods at mines where formerly, under other owners, the work was done underground.

EXIGENCIES OF OPEN-CUT OPERATIONS

At first glance it would seem as if when a yard either of ore or of waste can be dug out by steam shovels for 32c. that the cost per ton would be approximately 13c., and that, therefore, it would be as cheap to mine almost 7 tons in an open pit as it is to mine 1 ton underground. In other words, 6 tons of stripping might be removed to secure 1 ton of ore. This would be the case were there no expense involved in mining except the actual digging.

As a matter of fact, there are other expenses that amount to considerable. One of these, the interest on the money thus locked up in stripping, I have already pointed out, but a still more important cause for hesitation in adopting open-pit mining to its full apparent limit is the considerable variation in the cost of steam-shovel work in different parts of the same mine. Where the ores are soft and uniform a steam shovel will undoubtedly dig a large amount of ore. In some mines the cost of digging ore for a period may go as low as 6 or 7c. per ton, but this may be followed by another period when the costs may be several times as high.

For instance, in 1906, at the Mountain Iron mine an output of 2,560,000 tons was obtained with a force of 500 men. The bulk of the work was done in eight months, say 200 days. At an average cost of \$4.25 per man per day we get for this period a total cost of about \$425,000. Supposing that for the remainder of the year one-half the force was occupied, we must increase the estimated cost by about \$125,000, making a total for the year of \$550,000. This equals 21c. per ton. In 1907, with an output of 1,973,000 tons 1200 men were employed. This indicates a cost of more than 65c. per ton.

OPEN-CUT MINING COSTS VARIABLE

A part of the increase was due, no doubt, to an additional volume of the stripping undertaken, but a considerable part of the increase cannot thus be explained. In the orebody itself changes were encountered that not only diminished greatly the output per steam shovel, but also greatly increased the number of men employed per shovel. Up to 1906 the total number of men required in shops, train crews, track laborers, etc., per steam shovel never exceeded 75; since then it has been 100.

The reasons for this are: (1) Ore itself has become much harder, frequently breaking into great slabs and chunks that have to be sledged to make them suitable for reduction in the blast furnace. (2) Owing to the irregularity of the bottom of the deposit it is often impossible to provide adequate working faces for the steam shovels, so that along the bottom and sides the shovels frequently have to

take shallow cuts, and sometimes the shovels suddenly run into worthless bars of rock. When the last occurs the machine must be moved to a new working place. (3) Boulder-like masses of worthless country rock occur in the ore which must be removed as waste. Consequently the excavation of ore by steam shovels, after the stripping is all done, may be much more expensive than is popularly believed.

UNWATERING THE OPEN PITS

The cost of pumping must be fully as high for open-pit as for underground mining and must be kept up just as steadily. The great pits form catchment basins, often many scores of acres in extent, and in the event of heavy rains, which are far from uncommon on the Mesabi range, the volume of water is often so great as to cause work to be suspended. Fortunately the ore is porous so that the pumping may all be done from a single shaft so located as to provide for the drainage of the entire orebody for all times. The volume of water ejected from a single orebody is frequently 5000 to 6000 gal. per minute. I estimate that when 5000 gal. per minute is pumped from a depth of 300 ft. and the output is 1,500,000 tons per year, the cost of pumping will be 7 or 8c. per ton. I suppose this is about a maximum cost for the Mesabi.

Now, returning to the question of where open-pit work should end and underground mining should begin, we find that the conditions are about as follows: The actual cost of digging ore in a pit where the ore is hard and sorting is necessary may run up as high as 40 or 50c. per ton. This cost will be reached when a steam shovel with a crew of 100 men at an average cost of \$4.25 per day digs 20 cars, or between 800 and 1000 tons per day. The cost will not exceed 50c. per ton, because ore can be sorted and loaded as cheaply as that by hand without any steam shovel. Let us then put 50c. per ton as a maximum cost for digging.

The cost of administration, interest on development capital (largely stripping), and of pumping, is, of course, variable. Where 500,000 or more tons are mined in a year, all these expenses combined are not likely to exceed 15c. At the worst, then, we have 65c. per ton as the cost of mining in open pits, outside of stripping. Now, as underground mining will cost 90c. per ton, we have the difference between 90c. and 65c. to invest in stripping. This 25c. will remove 2 tons of overburden.

I therefore conclude that it will pay to remove 2 tons of overburden to 1 ton of ore, under the least favorable mining conditions. Under the most favorable conditions, where both the ore and the overburden are soft and uniform, the economical proportion may rise as high as 4 or even 5 to 1.

AVERAGE COST OF MINING ON THE MESABI RANGE

This is a point on which no one can get exact information without access to the cost statements of at least 50 different properties, but in a general way I think we can get a rough estimate that will be sufficient for practical purposes. It will appear that the actual mining cost of the ore at the mines is not, after all, one of the greatest factors in the final cost of producing pig iron.

Returning to our output per man per day as a basis for calculating costs I find that during 1907 the mines of the Steel Corporation in the Hibbing district produced approximately 9,000,000 tons of ore. This ore came largely from great open-pit properties, but some of it came from underground mines. I am informed that the total number of men employed was about 4500 with 60 steam shovels. Supposing that the whole of this force was employed for eight months, and half of it for the remaining four months of the year, and assuming that 26 working days constitute a month, we get an equivalent of 260 days with 4500 men, each costing \$4.25. This gives us a total of approximately \$5,000,000, or in round numbers, 55c. per ton.

This estimate is open to doubt on several points, two of which are whether the amount of stripping that was done kept pace with or exceeded the amount of ore extracted, and whether the rough figures of labor employed are actually near the truth.

As to these facts I have no means of judging except the most general impressions, but I am satisfied that at the worst, my information is not far enough astray to make the cost hopelessly inaccurate. In a general proposition of this kind no one attempts to get down to niceties, and there is no occasion for it. When I state that the average ore mined in the Hibbing district costs 55c. per ton, I may be 15 or 20 per cent. astray this year, and next year I may be right.

The mines of Hibbing undoubtedly are the most favorable on the Mesabi range for cheap costs. They have the largest, softest and most uniform orebodies, and are worked on the largest scale. It does not seem improper, therefore, that if we estimate the cost at 55c. per ton at Hibbing, we should increase this to 60c. for the whole range. I therefore estimate that the average cost of mining on the Mesabi range for both underground and surface is about 60c. per ton, exclusive of taxes.

TAXES

The laws of Minnesota tax mining properties for what ore they have in sight. The tonnage developed is reported by the mining companies to the assessor who puts a valuation upon it according to the quality and accessibility of the ore. For purposes of taxation, discovered ores are placed in five or six different grades with a minimum valuation of 8c. per ton and

a maximum of 33c. Roughly, the ore developed seems to average about 15c. per ton in valuation. This valuation is taxed just as any other assessed property is taxed, the levy being somewhere in the neighborhood of 1½ per cent.

Since the Steel Corporation has in Minnesota on the Mesabi and Vermilion ranges about 930,000,000 tons on the assessors' lists, it would appear that the total valuation would be somewhere in the neighborhood of \$14,000,000 and the taxation approximately \$2,000,000. On this basis we find that the company must pay on its present output of approximately 18,000,000 tons, more than 10c. per ton on its actual shipments.

This taxation is a recent development. I do not believe that the company has as yet actually paid so much, but on a basis of present and future conditions it does not seem like an excessive estimate. The fairness of this mode of taxation it is not my present purpose to discuss, but it is very evident that a company with large ore reserves and a small output may be taxed much more than a company with a large output and small ore reserves. For instance, if the Steel Corporation had only five years' ore in sight instead of 50 years its taxes in its present tonnage would be only 1c. per ton instead of 10c. For this reason there are probably vast differences in the tax rates of various companies on the Mesabi range, and I suppose the Steel Corporation undoubtedly pays more taxes per ton of output than any of the others.

EXPLORATIONS AND MAPS

It may be interesting to digress for a moment to consider the value of combination in the operation of these mines. Since its organization the Steel Corporation has pursued a most complete, scientific and satisfactory plan of exploring and mapping its ore reserves. It has employed expert geologists and engineers for this purpose. It has secured as much land as it could for exploration and has explored them to the point of determining, before any mining is done, the situation, volume, shape and economic characteristics of the orebodies on large tracts of land.

In other words, the process of drilling and test-pitting has been carried on until the depth of surface, the quality of the ore, its probable admixture with boulders and tongues of barren rock, and its thickness have all been determined. This information is expressed on maps which show the contours not only of the surface of the land, but also of the surface of the orebody underlying the glacial drift and the contours of the bottom of the orebody.

The information permits the planning of the mining work in such a way that there shall be no duplication of effort. The drainage of an orebody can be provided for with a single shaft so situated

that it reaches the bottom of the deposit. The problem of mining is solved beforehand. In other words the propriety of mining in open pits or underground is predetermined. The location of pits, of dumping grounds, of railroad tracks and of all equipment is established once for all.

DRAWBACKS OF INDIVIDUAL MANAGEMENT

Now, suppose these same orebodies were to be mined by different companies as was, or would have been, the case 20 years ago. The orebodies are sometimes a mile or even two miles in length and quite irregular in outline. The ordinary course of the longest axis of an orebody is northeast and southwest so that it would cross the subdivisions of the land diagonally. Such an orebody would inevitably occur on several sections, quarter sections or 40-acre tracts. The land ownership is scattered and irregular. It is seldom that any tract belonging to a single owner is larger than 160 acres and many tracts are only 40 acres in area. As a matter of fact most of the great orebodies on the Mesabi range belonged originally to five or six different companies.

In such a case it is evident that each company would have its individual management, its own problem of finance and its own requirements in the way of output. The mine located on one particular 40-acre tract might find the surface only 20 ft. deep, and it would plan an open pit. Since the neighboring ground was seldom thoroughly explored, the waste from this open pit might very likely be, and indeed was in many cases, dumped on ground afterward proved to be ore-bearing.

The next mine on the same orebody might find the surface to be locally too ft. deep, and if the operating company were poor and in a hurry for ore, it would undoubtedly open up its mine underground. The result of this would be that large sections of the surface would be caved down into the middle of the ore, thus preventing forever the successful stripping of that part of the orebody.

ECONOMY OF LARGE OWNERSHIP

But if this whole orebody were in the possession of the Steel Corporation, its explorations might show that the surface averaged about 50 ft. and that it might be economical to mine all the ore by an open pit. A single pump shaft would be sufficient. No waste would be dumped on neighboring ore-bearing ground. In short, a vast amount of duplicated expense would be avoided. This is where the value of such a combination comes in.

The Steel Corporation cannot get its work done any cheaper than anybody else. If it has to sink a shaft, for instance, it cannot do it any cheaper than any one of the half dozen mines that it might replace, but it could on the average sink one shaft for one-sixth the expense that

it would cost other people to sink six shafts.

It is worth remarking in this connection that the Steel Corporation has been magnificently managed. It has not striven for minute and near-sighted economies. It has not tried to outdo its rivals in points of local rivalry, but it has kept in mind the broad outline of its operations and has tried to make use of its capital and opportunities in ways that every fair-minded man would recognize as legitimate. The company can do this only as long as it is well managed, but up to the present it is only fair to say that its activities have been well directed and that its economies are such as to be certainly of no disadvantage to the public at large, but on the contrary in many ways a great benefit.

TOTAL COST OF ALL LAKE SUPERIOR ORES

In order to keep the proportion of things in mind, even at the expense of some repetition, we may state that the cost of mining Lake Superior iron ores is for Mesabi ores, \$6.60; old range ores, \$1.15 a ton. Since the Steel Corporation mines about 7 tons of ore on the Mesabi range for over 3 tons mined on the old ranges, we may calculate that the actual cost of 10 tons would be \$7.65 or 76½¢. To this we must add taxes which on the Mesabi range are not far short of 10c. per ton. In order to make a round figure we may state that all Lake Superior ores would cost on the ground about 85c. per ton, including taxation. To this we may add 40c. per ton for royalty, making the total cost of Lake Superior iron ores at the mines, ready for shipment, \$1.25 per ton.

TRANSPORTATION OF ORES

The ores which are mined on both shores of Lake Superior either in northern Wisconsin and Michigan or in Minnesota, must all be transported to the region lying south of the Great Lakes for smelting. The region of iron manufacture extends from the neighborhood of Chicago and Milwaukee at the northwest, eastward in a widening belt to Pittsburgh and Buffalo and thence east to the neighborhood of New York City.

The factors which dictate the production of pig iron in this region are two, namely, the presence of coal and facilities for distribution. If we take Pittsburgh as the most active and central point in iron manufacture to represent average conditions we find that the ores must be transported about 1000 miles in three sections: (1) There is the land haul from the mine to Lake Superior ports; (2) the lake haul from Lake Superior to Lake Erie; (3) the land haul from Lake Erie to Pittsburgh.

The first division of the work is covered by five or six different roads—three in Minnesota and the remainder in Michigan and Wisconsin. The length of

haul is variable; from Ely, Minn., on the Vermilion range to Two Harbors, the distance is about 90 miles. Most of the ore from the Mesabi range has to be hauled from 70 to 100 miles so that I suppose an average distance for the north shore roads is perhaps 80 miles. Most of the ore on the Marquette range is less than 20 miles distant, while that on the Menominee range is about 50, and from the Gogebic range the distance is only about 30 or 40 miles to the harbor.

The published rates on ore from mines in Minnesota to the lakes is uniformly 80c. per ton; from the Gogebic range to Ashland, 40c.; from the Menominee range to Escanaba, 40c., and from the Marquette range to Marquette, 25c. In the case of any company other than the Steel Corporation it would be necessary to take these rates at their face value, but in this case there is reason to believe that the transportation is the most profitable part of the business.

The company does not own any railroads on the southern shore, but its two railroads on the northern shore, namely, the Duluth & Iron Range and the Duluth, Missabe & Northern, haul about 52 per cent. of the ore produced in the entire region. The corporation also owns a fleet of boats on the lakes, probably sufficient to transport an equal amount. It also owns the Pittsburg, Bessemer & Lake Erie railroad, which hauls most of the ore to Pittsburg. I think we shall not be far wrong if we assume that so far as costs go the results are the same as they would be if the company transported all its own ore from the Minnesota mines to the furnaces.

While the freight on ores from the south shore to Pittsburg is undoubtedly less than that from Minnesota, it is also true that the Steel Corporation must pay on ore transported from those ranges a profit to independent railroad companies which it does not pay in the case of Minnesota ores. Its profits on Minnesota ores which it hauls for other companies probably more than counterbalance the amount it pays in profits to others on the Michigan ores.

AUTOMATIC HANDLING OF ORE

Iron ore is about the most easily handled material in the world. Its specific gravity is high, so that the ton does not occupy much bulk, and it is absolutely uninjured by the roughest treatment. As a matter of fact, it is loaded directly into dump cars either by the steam shovels or directly from the mine shafts. It is made up in trains of approximately 2000 tons of net freight and hauled over roads of very slight, or no, adverse gradients to the lake docks. There it is dumped by gravity right into the hold of the ship and transported in large cargoes on waters that are generally tranquil, and unloaded by machinery at the lower lake ports to be

again delivered to the dump cars and carried as before to the furnaces.

I believe the operating cost of hauling such material by rail cannot exceed $\frac{1}{4}$ c. per ton per mile. On this basis transportation from the mines to Duluth would cost about 20c., and from Lake Erie to Pittsburg about 40c. per ton, making a total for rail haul of 60c. The lake freight in all probability will cost, including unloading, an average of about 40c. Thus we have a total transportation cost of \$1 per ton from the mines to Pittsburg. This, of course, is merely operating cost, and does not include the necessary return on the capital invested in the transportation properties, but this item I propose to consider as a lump to be added to the cost of pig iron so that I will not discuss it here.

We have, then, ore delivered at the furnaces at Pittsburg at a total cost of \$2.25 per ton, distributed as follows: Mining 85c.; royalty, 40c.; transportation, \$1.

COST OF COKE

Without going into details I think it would be fair to estimate the cost of Connellsville coke to the Steel Corporation at about \$1.40 per ton. This is on a basis of 70c. per ton for mining the coal and using $1\frac{1}{2}$ tons of coal per ton of coke at a coking cost of 35c. The freight rate from Connellsville to blast furnaces at Pittsburg is 75c. per ton, so that we may calculate coke delivered at the furnace at \$2.15.

COST OF PRODUCING PIG IRON

It is not probable that the average Lake Superior ore of today will yield much over 50 per cent. in pig iron before moisture is deducted. Since the tendency is toward a gradual reduction in the grade of the ore, it does not seem far out of the way to assume that two tons will be required for each ton of pig iron. We may now calculate when an average output of 10,000,000 tons of pig per year is made, the cost to be as follows: Use of capital, \$2.85; 2 tons iron ore at \$2.25, \$4.50; 1.2 tons coke at \$2.15, \$2.58; limestone for flux, 50c.; labor and maintenance at furnaces, \$1.40; general expense, 25c.; total cost at Pittsburg, \$12.08; freight from Pittsburg to New York, \$2.60; total cost at New York, \$14.68.

An interesting commentary on the correctness of these figures is the testimony of Judge Gary in the tariff hearings before the Ways and Means Committee of the House of Representatives. Mr. Gary gives costs for the year 1906 for all the furnaces of the United States Steel Corporation. His figures are those not of actual cost, but of market prices for iron ores, coke and transportation.

The figures are as follows: Iron ore at \$4.70 per ton; cost of ore used in a ton of pig iron, \$8.62; coke at furnace, \$3.93 per ton; coke used in making a ton of pig iron, \$4.15; limestone per ton, \$1.06; limestone in pig iron, 49c.; scrap, cinder

and scale, 27c.; labor and maintenance at furnaces, \$1.37; depreciation of furnaces, 40c.; total cost of making a ton of pig iron, \$15.30.

From these figures Mr. Gary makes the following deductions for net profits: On ores in pig iron, \$2.04; on coke in pig iron, 60c.; on transportation, \$1.07; total deductions, \$3.71. Subtracting this amount we have by Judge Gary's estimate \$11.59 per ton as the cost of pig iron at the furnaces.

There is, however, some doubt as to the exact application of the figures presented by Mr. Gary. Anyone who is familiar with testimony taken at a hearing will understand why this is so. I have gone over the evidence and put together the figures in another way. I do not know which is the most accurate.

MR. GARY'S FIGURES IN DETAIL.

Actual cost of iron mining at all mines	\$0.73
Actual cost of coke at ovens	1.21
Actual cost of iron ore at furnace	2.83
Actual cost of coke at furnace	3.39
Pig iron.	
Iron ore per ton pig.	5.50
Coke per ton pig.	4.07
Limestone	0.49
Cinder and scale.	0.27
Operating blast furnaces	1.38
	\$11.71
Depreciation of blast furnace	0.40
	\$12.11

It will be noted that the sum total of Mr. Gary's figures are almost identical with those of my independent estimates. It is to be pointed out, however, that Mr. Gary's figures are for all the furnaces of the company, while mine are for Pittsburg alone. This fact will make a divergence in the details unavoidable. Furthermore, my figures are for general conditions as they are at present, while Mr. Gary's are exact statements for a single year. After giving the matter considerable thought I have decided to leave my estimates as originally made. They will at least serve to show something of the logic of calculating costs.

One mine in Australia is being operated for rutile. It is owned and worked by Francis J. Spence, and is 45 miles north-east of Adelaide in South Australia. The present production is small, but could be increased at any time, if a demand should arise for the mineral, as for instance, from the use of titanium in making steel. At present the demand is not important. Rutile is valuable chiefly for its high titanium content, and its principal uses at present are in the coloring of porcelain and of artificial teeth and in the manufacture of some forms of arc lamps.

Hitherto the deepest borehole in the world has been that near Rybnik, Upper Silesia, 2003 m. This depth has now been exceeded by a hole at Czuchow, in the same district, which has already reached 2156 m., and is to be continued to 2250 m., if possible. The hole was commenced in December, 1906, with a diameter of 16 inches.

The Mount Morgan Mine, Central Queensland

An Enormous Body of Ore Which Supports 12,000 People and Has Produced \$70,000,000 of Which \$37,000,000 Were Paid in Dividends

BY J. BOWIE WILSON*

Lying within the coastal edge of the hills that traverse the eastern side of Australia parallel to the coast the Mount Morgan mine, Central Queensland, has an altitude of about 800 ft. above sea level. The climate, although semi-tropical, is healthy, the extreme heat of the summer days being tempered by almost invariably cool

condition which I think tends to show that even the tropical portions of Australia, when once clear of the low-lying strip of coast country, are suitable for a white population. From the very beginning of the Mount Morgan company the whole of labor employed has been European, or the descendants of European settlers.

government, which junctions with the main central line at Kabra.

Mount Morgan has a population of 12,500, and is an up-to-date mining town, having an excellent hospital, school of arts, a technical college, a local telephone exchange which is also connected with Rockhampton, and is lighted with gas sup-

MILLING SYSTEM, SHOWING FUNNEL-SHAPED PITS AT SURFACE

nights. The atmosphere is dry and no tropical fevers are prevalent.

The climate is one in which white men can easily work and without apparent deterioration. A large percentage of the men now working at Mount Morgan have either been there for 20 years, or were born in the district; and it would be hard to find a body of men in better physical

MOUNT MORGAN, THE TOWN

The town of Mount Morgan, called after the mine, has been built just outside the mine works upon the banks of the Dee river, which in common with so many so-called Australian rivers contains running water only during the rainy season. The town is connected with the Queensland government railways by a short branch line 12 miles long, also built by the

plied by a private company. The inhabitants depend wholly upon the Mount Morgan company for their support, as there is only the one producing mine in the district and the surrounding country is worthless for either agricultural or pastoral pursuits.

The fact that up to the present no payable mines have been located outside the Mount Morgan company's holdings is

*Mining engineer, Sydney, N. S. W.

often commented upon, but when it is remembered that this company secured 750 acres in the early days and still retains them, having sold only the surface rights of a few blocks near the town, it is not surprising that they hold all the valuable portions of the ore deposit.

WATER SUPPLY

The town depends for its water supply wholly upon what each individual stores in tanks from the catchment of his dwelling; as the rains are erratic and the district must be considered a dry one, the supply

capacity of the works has also increased, so that even today the company is not in too good a position to withstand a prolonged drought.

THE ORE DEPOSIT

The Mount Morgan deposit was discovered in 1882, quite by chance, by the Messrs. Morgan, when they were returning to Rockhampton after an unsuccessful attempt to locate a reported silver lode on Nine Mile creek, about 19 miles from Mount Morgan, and which, by the way, has never yet been located. Heavy rains

away, to Rockhampton and the returns were all rich. After another trip to the locality they pegged out claims and formed a local syndicate in Rockhampton to develop their discovery. The mine was practically self-supporting from the start, only a few thousand pounds being put into the property. The syndicate worked the property until 1886. No records of their profits during this period are available, but in that year they formed themselves into a limited liability company of 1,000,000 shares of £1 each issued as paid up to 17s. 6d. per share. The flotation of the company

CRIBBING USED IN THE COPPER-GOLD OREBODY

of good drinking water frequently runs short. The company has built seven dams across the Dee river at different sites to supply the works with water, of which the four largest are still in use. When full these have a capacity of 370,000,000 gal., but even with this supply the works have several times been threatened with stoppage through a shortage of water. During the big drought of 1902 for seven months all the water required by the company was carried from Stanwell about 17 miles by rail. The storage capacity has since been increased, but the treatment

falling, the creeks became flooded, and the prospectors were forced to camp in a deserted shepherd's hut on the Dee river. While waiting for the creek to fall, one of the Morgans, taking a dish and pick, went prospecting, and in passing over the hill now called Mount Morgan noticed some peculiar iron-ore boulders, pieces of which he broke off, and carrying them down to the water, crushed them and panned off. He obtained such a rich prospect that he could not believe that it was gold in the pan.

The Morgans took samples back, far

was purely the transferring of the existing syndicate into a company as all the shares were allotted to the members of the syndicate in proportion to their holdings. The company remained in this form until 1902 when the directors made a call of 2s. 6d. per share and at the same time declared an extra dividend of 2s. 6d., thus making the shares fully paid up and taking away all liability from shareholders.

The origin of the deposit is still open to discussion but it must clearly be classified as belonging to the class of impregnations or metasomatic deposits. The

country rocks around mount Morgan are of sedimentary origin belonging to the Gypmic series of the Permo-Carboniferous age, but they have been greatly altered by dolerite dikes and intrusive masses of hornblende granite and now appear as quartzites and quartz felsites.

OPEN-CUT MINING

The open cut was started in the early days of the mine by benching the orebody on the top of the hill and this has developed into the present huge quarry. At first it was not realized that it would pay

the works bins. When the west works were built upon the side of the hill, to replace the old lower works and to treat the oxidized ore, a main tunnel was driven right through the hill upon the level of the works hoppers (285-ft. level) and all the oxidized ore was passed down to this level and drawn to the hoppers, at first by two small steam locomotives and later by electric motors.

MILLING SYSTEM

This bench mining has now been abandoned as much as possible in favor of

poor ore are of any size it is possible, in milling, by carefully placing the shots to shoot down ore and waste separately when the waste can go straight to the tip or to the waste passes for filling in the underground stopes.

In mining out the old filled-in stopes, the timber is recovered and, being all hardwood, iron bark and spotted gum, most of it is sound enough to be used again in the mine. As the tenons of the legs are often broken, these are either cut into caps and struts or used for double banking a weak set, or for temporary pig-

HEADFRAME AT MAIN SHAFT

to remove the whole top of the hill and a lot of money was wasted by mining by the square-set system ore that should have been quarried in an open cut. For instance, on the Grantree level or floor No. 21 (315-ft. level) more than 2000 sets were mined, each set being 6x5x7 ft. 9 in. high, and now the open cut is down to the 360-ft. level.

The open cut was originally worked like an ordinary quarry in benches, the ore being shot down from the faces upon floors, shoveled into trucks and tipped into passes leading to drives upon the level of

the milling systems in which a rise is put up, to act as an ore pass, from a drive to the surface and then the material worked out around the pass until it has the appearance of an inverted cone with the top of the pass at the apex. The milling system would be used exclusively, but for the fact that in parts of the present open cut old filled-in workings occur, and it is not always convenient to get the necessary drives and rises in the proper positions. With bench mining it is also easier to hand-pick the ore, and in places this is advisable. Where the dikes or bands of

sties in the copper chambers for supporting a bad piece of roof.

Down to the 315-ft. level practically the whole of the ore removed from the open cut was oxidized, but at about this level the ore changed to sulphide and now all the eastern side of the open cut is in un-oxidized ore. The change from completely oxidized to sulphide ore is remarkably sharp taking in places only a few feet to change from the one to the other.

ECONOMY OF OPEN-CUT MINING

The economical limit of an open cut is

reached, or course, when the cost of removing waste to allow a safe batter to the sides of the quarry, per ton of ore exposed equals the difference between open-cut and underground mining. It was estimated at Mount Morgan that this point will be reached when 450 ft. below the original summit of the hill.

To handle economically the overburden that had to be removed to allow this depth to be reached, in 1903 a 65-ton Bucyrus steam shovel was imported and erected. I believe that this was the first shovel of any size to work in Australia. It has done excellent work at Mount Morgan, its only disadvantage being that the type in use

quite possible to open-cut the center of the deposit below this level.

There is one great disadvantage in an open cut. In spite of drains, wherever possible, it acts as a catchment area for the mine and when the rainy season is on it pours a large quantity of water into the mine. This would be more serious in a locality blessed with more rain than central Queensland.

SQUARE-SET MINING

The square-set method was adopted for the gold ore when underground mining was first started and it is still in use in

that it can be worked round again if a new discovery shows this to be profitable or a reduction in treatment costs converts unpayable ore into payable.

The square-set system readily adapts itself to the keeping of accurate assay plans, as the exact position of each set can be obtained without excessive surveying. As all underground mining is done by rock drills, the sample of a set is taken by mixing some of the borings from each hole put in to mine the set. In an orebody like the Mount Morgan deposit where the gold cannot be seen and the gold is very fine and generally evenly distributed this method of obtaining samples is fairly ac-

OPEN CUT, FREEHOLD LEVEL, SHOWING TIMBER IN OLD STOPES

can work only on a siding as it will not clear enough room in a heading to allow a train to run beside it.

To do this work a shovel of English design, a Witaker, was imported. As this style of shovel revolves completely round, it can discharge into trucks at its rear and so can work in a heading and prepare the way for the Bucyrus shovel, but for quickness of work and cheapness it is not to be compared with the Bucyrus. Three 10-ton locomotives, of English make, running upon a 3½-ft. track, took the waste away from the steam shovels.

Although the sides are only being removed to allow a safe batter to the edge of the ore on the 450-ft. level, it will be

the older part of the mine to the east of the andesite dike. This method of timbering is safe and holds ground well, when care is taken to keep the sets filled close up to the workings, but it is undeniably expensive. Still, even in the face of the expense, I fail to see how it would have been possible to adopt a cheaper system of mining this part of the deposit, when the payable ore occurs in the midst of masses of unpayable rock and one can never be quite certain where a stope will end when starting it. The square-set system can be expanded and contracted at will without interfering with the safety of the stope and by slabbing up the outside sets before filling in, it is possible to leave the stope so

curate. It has frequently been checked and has always been found to give close results.

Of course in practice before mucking a set that has given a low assay return, the value of the surrounding sets is taken into consideration, and if it happens to be in good company, it is considered safe to send the material to the works hoppers if there is no time to check the sample. A set of ground equals about 20 tons on the average, and a separate assay is made for each set. Assay plans were only started in 1902, and they have been found invaluable, and the even grade of the ore sent to the works can be largely attributed to their use.

CHAMBER AND FILLING

When the copper-gold orebody was prospected and blocked out by bore holes it was found that it would pay to mine completely a large area of the deposit. To avoid the costly timbering of the square sets it was decided to mine this body of ore in chambers. As the south dike, 20 ft. thick and practically vertical, runs through this body of payable ore and parallel with its greatest length, it was decided to run the chambers parallel with the dike, and to make use of it as a wall between the first two chambers.

These chambers are 60 ft. wide, and the length depends on the extent of the payable ore. On the 750-ft. level the chambers have an average length of 400 ft. The

cross-drives which pass through the dike. By side stoping from these drives the sill cuts of the chambers were mined. While this work was proceeding winzes were sunk, about 100 ft. apart, from drives on the level above to act as passes for the waste required for filling in the stopes.

If the level below is already opened up it is best also to sink winzes to it, as it is easier to do the work at this stage than afterward from the drive kept open through the filling. These winzes are also convenient for ore passes when removing the ore broken in the second cut of the chambers and before the filling is run in.

STOPING AND FILLING

After the sill cut has been mined, only

the chambers have to be worked so that the shaft can be reached through the cross-drives, connecting the two chambers. This is the simplest way, but to do it one chamber has to be mined in advance of its neighbor. When laying out the work this necessity of removing ore from the face of the heap must be kept well in mind.

After the second cut has advanced sufficiently to allow some of the broken ore to be removed, still leaving sufficient upon which to rig the machines at the face, the broken ore is shoveled away. When a section of the chamber has been cleared poles are laid across the floor and slabbed over; a drive is formed of two parallel pigsties roofed over with poles covered with slabs and filling poured into the

STEAM SHOVEL NO. 1 ON FREEHOLD LEVEL

width of payable ore greatly exceeds the combined width of these two initial chambers, the outside walls of both being composed of ore of much the same grade as that mined; additional chambers parallel to these are opened up when required.

The width of 60 ft. was decided upon because it was not thought prudent to have a greater width of practically unsupported roof open at one time especially as the walls of the dividing dike, being partially decomposed, cannot be greatly relied upon, and if the dike is eliminated there is at present 140 ft. between the outside walls.

To start the chambers, drives were first driven down the center of each chamber and connected at the middle and ends by

an occasional pillar being left in to help support the roof, the second cut is mined from the chambers by overhand stoping to raise the roof to about 20 ft. This was done by first cutting across the chambers, at the end nearest the shaft and then advancing in a breast up the chamber. The machines were rigged upon the heap of broken ore, the top of which was kept about 7 ft. from the roof.

Before firing the holes bored in the breast, sufficient ore was removed from the face of the heap to make room for the rock to be broken by the firing, and to leave room to rig up again after the roof had been worked down. To do this either a trucking way has to be kept open by timber through the heap of broken ore or

chambers and leveled off to within 5 ft. of the roof, when the third cut can be started. Pigsty chutes are built up through the filling at short intervals for passing the ore down to the drive. The filling is allowed to lie against the dike, but a pigsty is built along the outside walls of the chambers to keep the filling from the ore left there and also to keep the filling in place when the next chambers are to be mined. The flooring is laid so that the stope coming up under the chambers may be worked right up.

OTHER DETAILS

In filling in the chambers the waste is conveyed in side-dumping cars by an electric motor to the required pass and poured

into the chamber until the natural slope of the heap reaches the roof of the chamber and blocks the pass. Shovelers are then put on, and starting on the sides of the heap at the desired level, throw back the filling until they have filled in as much of the chamber as can be reached in this way. Just before this point is reached they stop putting waste into the top of the pass to allow the shovelers to empty it and to level off the heap under it. A rough chute is then put in the pass by running holes up the four corners and slabbing them in, when the remainder of the required filling is drawn off in cars. The filling passes were spaced 100 ft. apart, but they could have been closer with advantage.

The rock at Mount Morgan is, on the whole, excellent standing ground, or this method could not, of course, be used, but trouble occurs in the neighborhood of the small dikes, when temporary pigsties of

containing on an average 18 cwt., in single-deck cages with the usual safety appliances.

In 1905 when the copper-gold orebody was being developed and the smelting works were erected, a new shaft was sunk to handle the increased output of the mine and also to replace the old shafts, and to allow the surrounding ore to be mined. This shaft, called the incline shaft, was placed upon the southern side of the hill and with its mouth outside the deposit and upon the 315-ft. contour which is the level of the mundie works hoppers, and about 70 ft. above the smelter hoppers.

It is a three-compartment shaft 17x8 ft. over all, and is sunk on an angle of 45 deg. The two hoisting compartments are each 5 ft. 6 in. wide, and in the other compartment a stairway is built. It is connected with the mine workings on the 450-, 574-, 650-, 750- and 850-ft. levels, and was in 1908 sunk to the 950-ft. level. The ore is hauled in skips running upon rails and

are sunk to a tunnel upon the level of the smelter bins, the ore being drawn in large hopper cars by a steam locomotive to the bins.

INCLINE SHAFT

The incline shaft is intended for handling ore only; all men and supplies enter the mine on the 450-ft. level and are at present lowered down one of the old shafts. To free this old shaft and more economically handle the men and supplies the Linda shaft is now being sunk. This shaft is really an inclined tramway, as it is going down on a grade of 1 in 3. It starts at the mouth of the Linda tunnel (450-ft. level), and will connect with all the main working levels.

Although the cost of this shaft will exceed by about £2000 the amount for which a vertical shaft could have been sunk, clear of the deposit, it is expected that this amount will be saved in a couple of years

OPEN CUTS AND DUMPS, LOOKING SOUTH

timber have to be erected to protect the men. These can generally be completely recovered as the slope is filled, fresh ones being built up from the filling to pick up the roof. This work often requires great skill and ingenuity on the part of the underground boss.

Although to miners accustomed to small, well timbered stopes, these chambers look unsafe, up to the present there have been no accidents at Mount Morgan that can in any way be attributed to this method of mining.

SHAFTS

Until the beginning of 1907 all the shafts in use were small and vertical with three compartments, 10½x6 ft. in the clear. They were sunk in the orebody and none of them hauled ore directly to the surface. Their engines were underground, driven by compressed air, and they hoisted ore to tunnels upon the level of the works ore bins. All the ore was handled in cars

capable of holding from 5 to 6 tons; they are filled by chutes from pockets sunk from the various levels to the roof of the shaft. The main levels have each two pockets, so that either gold ore or copper-gold ore can be drawn as required.

The skips are self-dumping and discharge into a small hopper at the top of the headgear. This hopper is kept small so that when the class of ore being hauled is changed it can be emptied in a few minutes. The ore passes next through a Gates breaker which discharges upon a belt conveyor, which runs the length of the headgear. If the ore being broken is gold ore for the mundie works the conveyor, by means of a tripper, distributes it along the hoppers which form the base of the headgear and from which it is drawn in side-dumping cars by an electric locomotive to the works hoppers. If the ore is for the copper smelters the belt delivers into one of four ore pockets which

by the decreased cost of handling the men and materials. The vertical shaft could not have been sunk from the surface; so that all steel and material would have had to be handled as at present, which is as follows: Loaded upon trucks and trucked to the shaft plat, unloaded and loaded upon the cage, lowered to the required level and unloaded from the cage on trucks again. All this handling is expensive and also hangs up the shaft a lot during the loading and unloading of the cages. With the new shaft as each level is connected with the shaft by a turnout, on a vertical curve, the material once loaded on the cars can be lowered down the shaft and shunted to the level and left there ready to be taken to the working face. Although a much greater distance has to be sunk the cost per foot is about one-third of that of sinking a vertical shaft and no expensive headgear is necessary.

BREAKING GROUND

The rock drills in use are the Ingersoll-Rand-Sergeant auxiliary valve. All machine steel is sharpened in Ajax drill sharpeners, two machines being in constant use on three shifts with a third machine kept as a stand-by. Blasting powder is used in the jumper holes in the open cut, the holes being bulled with dynamite. Underground, Nobel's gelignite and No. 1 blasting gelatin are exclusively used, the latter in the harder ground, but sometimes only for bringing out the cut, the side holes being then fired with gelignite.

LABOR CONDITIONS

The open cut is only worked on a day shift of eight hours. Work starts at 7:30 a.m., and ends at 5 p.m., with two spells of $\frac{1}{4}$ hours each at 10 a.m. and 3 p.m., and $\frac{1}{2}$ hour at noon for dinner. On Saturdays the men knock off at noon, but it counts as a full day, the extra $\frac{1}{2}$ hour worked bringing it up to seven hours, so the men work only 47 hours a week, but are paid for 48 hours. All work in the open cut is done on wages.

In the gold stopes the work is cut at so much per square set erected, and in the copper chambers at so much per ton of ore delivered to the chutes. Contracts are let for a period of eight weeks, all the contracts being let upon the one day, so that all the miners have an opportunity of tendering for each job. All tenders have to be delivered at the mine office in a closed envelop, and if on opening the tenders the lowest is not considered satisfactory, the work is either done on wages or left until the next contracts are let.

Progress payments are made fortnightly, on the same days as the wage men receive pay, but 10 per cent. is withheld until the satisfactory completion of the job. Contractors supply all explosives, candles, machine oil and fuse, but the company supplies air, machines, tools (which later must be returned in good condition), and timber; the contractors must erect the timber to the satisfaction of the mine manager. The contracts are let to small parties of men (generally 12) and half of them have to be in the contract and sign the specifications.

Although the contracts average more money than can be earned on wages, still the work is done cheaper per foot and per ton than can be done by the company itself on wages work. The contract system has never given any trouble at Mount Morgan.

The Hamilton Iron and Steel Company, at Hamilton, Ont., is about to install the Gayley dry-air blast at its furnace. The contract for the refrigerating plant has been awarded to the De La Vergne Machine Company, New York. Frank C. Roberts & Co., Philadelphia, are doing the engineering work.

Aluminum Direct from Bauxite

The practice in aluminum reduction is first to purify the bauxite by one smelting operation, and then to treat the refined alumina in the reduction furnace. This is necessary from the fact that the usual impurities in bauxite are more easily reducible than the alumina, and having once found their way into the aluminum, are difficult to separate commercially. The extra expense of this procedure, arising from the larger plant required and the loss of heat, has led a German inventor (German patent No. 204,004) to propose a process whereby the purification of the alumina and the reduction of the aluminum go on more nearly together, with the liberation of a valuable by-product.

The crude bauxite is mixed with carbon and a boron compound, and treated in the electric furnace. The iron and silica go into combination with the boron, forming an exceedingly hard material which has a commercial value as an abrasive, while the pure alumina passes to another part of the same furnace, or to another furnace, if desired, for reduction into aluminum, in the usual way.

Copper in the Transvaal

SPECIAL CORRESPONDENCE

The report issued by the Messina Copper Mining Company shows that, although the Transvaal's only copper producer is of small concern in comparison with the mines of other countries, it is at last assuming a permanent place among the colony's few base-metal properties of profit-making capacity. Ore reserves are now estimated at 27,782 tons containing 16.3 per cent. copper. The plant erected consists of rolls, jigs and Wilfley tables capable of treating 50 tons of ore per day. Situated in the extreme northern Transvaal, the Messina district suffers severely for lack of cheap and rapid transport. By improved roads, the \$1.44 cost of mule and donkey transport has been reduced to 90c. per lb. Since the war, the government has adopted a vigorous policy of branch-line construction, but there are two regions of importance from the mining standpoint, which still urgently need practical assistance in this respect. First, the Lydenburg goldfields, which record an output worth £450,000 per annum, and second, the Zoutpansberg district, to the north of the railroad at Pietersburg. That a line will shortly be built as far as the southern part of the Lydenburg field is practically assured and it is now further reported that negotiations with the government have been satisfactorily concluded with regard to the service of the Zoutpansberg region.

Ontario Mineral Production

The Mines Department of Ontario has made a preliminary report of the production of that Province in 1908. The metallic production is reported as follows:

Gold	ounces	3,465	\$60,337
Silver	"	19,424,781	9,125,903
Cobalt	tons	2,224	110,166
Nickel	"	10,175	1,869,059
Copper	"	7,561	1,071,140
Iron ore	"	199,395	537,379
Pig iron	"	271,656	4,390,839
Total value			\$17,161,823

From the total value must be deducted value of 170,215 tons Ontario iron ore converted into pig iron in the Province; this was \$456,176, making the net value of the metallic production \$16,705,647. The valuation of all the metals was lower than in the previous year.

The silver mines of Cobalt yielded 9,000,000 oz. more than in 1907, but owing to the fall in the price of silver the value was not correspondingly greater. Shipments of ore from the silver mines amounted to 24,485 tons. A little less than a third of the total tonnage was treated in Canadian reduction works, most of the remainder going to the United States, and a small amount to Europe. The ore treated at home was largely high-grade, the lower qualities being sent mainly to smelters in the United States.

The value of the non-metallic products is reported as follows:

Arsenic, refined	tons	702	\$10,373
Arsenic, crude	"	2,970	"
Calcium carbide	"	2,364	147,150
Corundum	"	141	14,977
Feldspar	"	7,755	20,300
Graphite, refined	"	10	1,600
Gypsum	"	10,380	20,778
Iron pyrites	"	20,970	69,980
Mica	"	368	73,586
Natural gas	"	"	969,160
Peat fuel	"	290	800
Phosphate of lime	"	881	7,448
Petroleum	Imp. gal.	18,479,547	703,773
Quartz	"	44,741	52,830
Salt	"	79,112	488,330
Talc	"	1,016	3,048
Total value			\$2,613,833

There was a considerable falling off in petroleum.

The output of building materials and clay products was as follows:

	Quantity	Value
Brick, tile, etc		\$2,600,000
Portland cement	Bbl. 2,022,877	2,417,769
Lime	Bu. 1,850,000	357,050
Pottery		50,510
Building stone		475,000
Total value		\$5,900,129

This brings the total values up to \$25,210,000. Values are computed at the selling prices at the mines or works, and in the form in which the substances are produced.

On the Rand, South Africa, the Randfontein and Langlaagte mines use one tube mill to regrid the pulp from 40 stamps; the Eckstein mines, one tube mill for 50 stamps, and the Gold Fields mines one for 10 stamps.

Methods of Mining Coal in New Zealand

Detailed Description of the Westport-Stockton Colliery, where the Equipment and Prevailing Ideas Are along the Latest American Lines

B Y S I D N E Y F R Y *

The latest addition to the coal mines of New Zealand is that of the Stockton colliery, which is situated in the heart of the bituminous coal areas of the South island.

The company which is operating this mine was floated by Mr. Munro, an enterprising citizen of Westport, and was incorporated in August, 1905, for the object of opening out and operating a coal lease of 1500 acres in area, which was afterward increased to 2000 acres. The chairman of

LOCATION OF THE MINE

The mine is situated about 20 miles northeast from the port of Westport; it is at an altitude of 2000 ft. above sea level, and back about 3 miles from the coast. The coal is delivered from the company's tram-lines and inclines into their bins, which are on the flat of the foot of the hills fronting the sea, and close beside the State railroad track. All the valleys in the neighborhood are covered with an abund-

and gneiss of probably greater age than Devonian.

The lowest member of the coal-bearing series is usually a bed about 20 ft. thick of conglomerate; this sometimes merges into a series of thin beds of shale, sandstone, conglomerate and arkose. Overlying this is the coal, the seam, varying from 10 to 20 ft. in thickness. Then follows a bed of silicious sandstone or grit 5 to 50 ft. thick. Then 20 ft. of brownish

FIG. 1. SHOWING DOUBLE-TRACK ROPE INCLINE WITH CARS PLACED AT REGULAR INTERVALS ALONG THE CABLE

the company is William Reece, a well known man of Canterbury, N. Z., and its engineer is G. H. Broome, who was at the time of the formation of this company, in charge of a colliery at the Crow's Nest Pass in Canada. This gentleman designed and equipped the mine on American lines, fitting it out with an electrical equipment which probably is not equalled south of the equator.

*Mining engineer, Westport, New Zealand.

ant growth of red pine, black birch (*Fagus fusca*, really a beech), and other useful New Zealand mining timbers.

GEOLOGY AND QUALITY OF THE COAL

The geology of the coalfield is simple; the coal measures, which are of cretaceous age, repose unconformably upon the upturned edges of highly inclined strata of granwacke and argillite of Devonian and Carboniferous age which are sometimes intruded by acid eruptives; and upon granite

gray micaceous sandstones, covered by 1000 ft. of sandstones and marly shales.

The foregoing is the series as they appear in dip section dipping under the sea at the foot of the hills, but there has been extensive denudation, and on the hills there is only about 100 to 200 ft. of strata overlying the coal.

The operators claim to have discovered two distinct seams of coal on the property, but they will find that this is purely

a local manifestation and that the two seams will soon unite, as they are simply different portions of the same main seam, and have been formed through the unequal rate of depression of a subsiding area, and of the rapid filling up of the more depressed part by sand or other sediment. Throughout the whole of the lease, the coal is lying at a very moderate angle of dip, and this together with the ample height of the seam has warranted the adoption of large sized cars for the conveyance of the coal within the mine.

The coal is an excellent grade of bituminous fuel as will be shown by the following analysis:

Moisture at 100 deg. C.	= 1.20 per cent.
Hydrocarbons	= 36.60 " "
Fixed carbon	= 61.12 " "
Ash	= 1.08 " "
	100.00 " "

Some of the coal is comparatively soft and its structure laminated; often it is

from one part of the mine to another affords no difficulty on account of the moderate dip of the seam.

VENTILATION

The main ventilation is effected by an electrically driven fan of improved Wadlie type, actuated by a belt from an induction motor which is fed through an oil-cooled transformer taking current from a transmission line and reducing it from a potential of 6000 volts, down to 500 volts. Several electrically driven Sturtevant auxiliary fans are also in use. There will be as few stentons as possible, to avoid leakage of air and also to allow of parcels being sealed off more effectively in case of fire.

HAULAGE PLANT

The traction in the mine, and from the mine mouth down to the top of the rope

dition to wheel brakes, the larger locomotives are fitted with Fell brakes for the operation of which each steeper gradient is provided with a center rail.

The overhead trolley system has been used both in the mine and outside, and a direct current of electricity with a voltage of 250 is employed. This involved a heavy first cost for copper, but was deemed advisable on the grounds of safety. The cars are lowered from the terminus of the electric tramway by means of endless ropes, and this is done in two stages. Both inclines are, of course, double tracked, the rails being 40 lb. to the yard. The haulage ropes are made of the best plow steel; that for the top incline being 4 in. in circumference and that for the bottom incline 3½ in. The cars are attached to the ropes by Craven's patent screw clips and are spaced at intervals of 2 chains. Both upper and lower inclines have been

FIG. 2. SHOWING INTERIOR OF THE DYNAMO ROOM AT THE WESTPORT-STOCKTON COLLIERY

hard, compact and structureless, and stands handling well.

METHOD OF WORKING

A main haulage road is being driven along the western boundary of the lease to its farthest extremity; here it will be opened out into a system of pillar-and-stall workings and the mine will be "worked home," the pillars being removed at the rear of the whole workings as early as safety and utility will permit. Like the rest of the mines in this locality, it will not be necessary to use safety lamps as the presence of inflammable gas, even a small quantity, is the exception and not the rule in these Westport mines; furthermore, the cracks caused by the settling down of the roof in the worked out areas, extend to the surface and afford ample opportunity for the escape of any free gas.

The coal is undercut by Sullivan machines; the transport of these machines

incline, which is 2¼ miles from the mine mouth, will be done by electric motors. The main locomotives are 20 tons in weight and can control trains of 20 cars, each car being capable of holding 1½ tons of coal. Six-ton locomotives are used for serving the working breasts with empties and for feeding the main drawing roads with full cars. From the mine to the top of the rope incline, the gradient is in favor of the load and averages 1 in 21 2; the steepest part of this grade is 1 in 12. The formation has been made of double width, so that the present single track may be duplicated when required in the future; this plan will make it possible to transport 2000 tons of coal per day.

The sharpest curve on the tramway is 2 chains radius, and it is formed of 65-lb. steel rails laid upon ties of yellow pine (a local timber) except at curves and at points and crossings at which places imported hardwood ties are utilized. In ad-

dition to wheel brakes, the larger locomotives are fitted with Fell brakes for the operation of which each steeper gradient is provided with a center rail.

The upper incline is 40 chains in length having an average slope of 1 in. 6.7; the steepest part being 1 in 5. The lower incline is 33 chains long and has an average grade of 1 in 4 and a maximum of 1 in 3. The two inclines are separated by a short-changing level, and each incline has its haulage rope controlled by vertical 4-cylinder hydraulic brakes, and to avoid the excessive side-grinding which is a feature of Surging drums, vertical pulleys are used; these are 10 ft. in diameter; the braking pulley having 5 rope grooves, and the idler pulley 4 grooves. These brakes impart a very even movement to the rope which is given a speed of 2 miles per hour.

At the foot of the lower incline the cars

are transferred to a main-and-tail rope which draws them to the bins in trains, through a tunnel 7 chains in length, having a grade in favor of the load of 1 in 63. Through this tunnel the track is single and is formed of 40-lb. rails. The haulage power is given to the ropes by an electric hoisting engine driven by an alternating-current motor working at a potential of 220 volts; the transformer which steps the voltage down from 6600 to that of 220 is situated in the main power station.

SCREENING AND LOADING PLANT

Ample siding accommodation has been made by the company, two miles of track having been laid out in shunting loops for the reception and quick despatch of the State railroad cars. On these sidings the coal bins have been erected; these latter are 50 ft. high, 100 ft. long, and in width span five railroad tracks; they are built of

jigger, passes onto a plate-band conveyer on which the coal is picked, and from which the unscreened bins are filled, the coal being lowered gently by means of alternate reversed chutes to save breakage.

The bottoms of the bins are provided with horizontal steel-plate sliding doors worked by means of hydraulic cylinders placed at each end of the bins, the pressure being obtained by an automatic accumulator. The plate-band conveyers, scraper conveyers, shaking screens, and distributing jiggers are all electrically driven by direct-current low-voltage motors.

THE POWER HOUSE

The power house is a building 174 ft. long, 50 ft. wide and 25 ft. high; walled with ferro-concrete and roofed with galvanized iron, and is divided into three rooms; the dynamo room, the condenser

Two small exciter sets are also used; these are driven by engines of the same type as the main generator engines, and are run at a speed of 600 revolutions per minute. They are used for the generation of direct current to excite the fields of the main generators.

In the dynamo room is also installed a 100-kw. motor-generator set which runs at a speed of 700 r.p.m., making current at 280 volts. This provides power for the screening and belt-conveyer machinery, also for the workshops and for lighting purposes. The switchboard is of blue-gray Vermont marble; the panels are fitted with ammeters, voltmeters, recording and indicating wattmeters, and a sensitively constructed Lyrrel regulator for automatically regulating the potential of the main generators.

All the alternating current switches are of the oil-break type and are placed in

FIG. 3. THE MAIN LOCOMOTIVES ARE 20 TONS IN WEIGHT, AND CONTROL TRAINS OF 20 CARS, EACH CAR HOLDING $1\frac{1}{2}$ TONS

Australian iron bark on a pile foundation, having a total capacity of 5000 tons. They consist of three compartments, two with a capacity of 2000 tons each for the storage of unscreened coal, and one of 1000 tons capacity for the reception of nut coal.

The tipplers are large machines of the side-revolving type; the full car running in, bumps the empty one out and the latter is automatically switched back onto the empty road. In the pulling of a lever by the attendant, the tippler swings gently over and quietly deposits the coal onto a distributing jigger, and thence, in the case of No. 1 tippler, over an end-shaking screen, and a retarding conveyer belt, to the railroad car, in which the screened coal is dropped with the least amount of breakage. The nut coal from this operation is lifted to the nut bin and automatically distributed in the same way by two flight conveyers. The coal from No. 2 and No. 3 tipplers, after leaving the distributing

room, and the boiler room. The main generating engines are vertical triple-expansion steam engines having a high piston speed, and are oiled by forced lubrication. They are coupled direct to alternating-current dynamos, which generate a three-phase current at 6600 volts with a periodicity of 60 cycles per sec., at a speed of 400 revolutions per min. Each machine provides 300 kw. at 80 per cent. power factor.

The alternators are capable of 10 per cent. continuous overload, 25 per cent. for two hours, and 50 per cent. momentarily without undue heating or strain. Two of these generating sets are installed at present, and are calculated to provide sufficient power for an output of 800 tons of coal from the mine per day; however, ample room has been provided for two more sets which will bring the power sufficiently high for an output of 2000 tons per day.

concrete cells at the back of the switchboard.

In the condenser room is a large surface feed-water heater which the steam passes on its way to the condenser; there is also a large hotwell, and a Webster vacuum feed-water heater which deals with the exhaust steam from the feed pumps and chain-grate-stoker engine. The boiler room contains four Babcock and Wilcox patent water-tube boilers, fitted with chain-grate mechanical stokers and with superheaters. The working pressure of the boilers is 150 lb. per sq. in., and each boiler has a heating surface of 1600 sq. ft., and a

fireclay surface of 34 sq. ft. with an evaporative capacity of 5000 lb. of water per hour.

Provision has been made for the accommodation of more boilers when required. A Sirocco fan provides ventilation for the building, which is splendidly lighted in the day by means of large windows arched at the top and framed altogether in cast iron, the illumination at night being provided by both incandescent and by arc lamps.

Working Two Coal Seams in Close Proximity*

By WALTER F. WHITE

The following is a brief description of the method employed at present in working two coal seams which have but 3 ft. of strata between them:

The two seams have been previously worked by several methods and modifications, viz., (1) pillar and stall, (2) bottom seam first and top seam after, (3) *vice versa*, and (4) longwall—upper seam first. The two first methods resulted in great loss. The result of the last method was that when the lower seam came to be worked it was greatly deteriorated in

9 in. of sod or shaly clay, which generally falls with the coal. Over all this is a thick bed of not very strong metal, being full of slips and joints.

The modification of working is evident from the sketches, which show the succes-

FIG. 1. Plan of Working

FIG. 2. PLAN SHOWING ONE GATE AND POSITION OF PACKS

sion of operations in the extraction of the coal.

There are five drawing gates on each side of the jig, stalls being about 36 yd. wide. Each stall is supported by from two to five rows of 4- to 6-in. diameter

per coal, beginning down the pack side and cutting up to within a few inches of the sod overlying the seam. We find it much the better plan to leave 4 to 6 in. of coal and prop to it, as the sod is of a very tender nature and causes a serious loss of coal if it falls and mixes with it.

As we cut down the coal, the supporting props being drawn one by one, of course set other props up to the roof or layer of coal that is left. As the coal falls, it is thrown down into the roadway at the face in the lower seam, or if possible it is filled into the car direct. A small portion of slack is lost by falling on the rough surface of the fallen fireclay.

At intervals of 5 or 6 yd. as we advance upward, openings are cut through the upper coal over the packwalls, to allow the ventilating current to sweep through, otherwise it becomes very hot in that portion of the face. Except where these openings are made, a rib of coal is left on the packs.

The fireclay is taken down in the gates, and when the face has advanced a short distance, the upper coal is also brought lower by the settling down of the whole strata above. The coal is then cut down in the gates, squared down by the pack sides and filled out.

FIG. 3. SECTION SHOWING COAL FACE

FIG. 4. SECTION OF FACE AFTER WITHDRAWAL OF BACK PROPS

quality and was rendered difficult to mine, especially in places that gave off water, which occurred somewhat frequently.

When a new district was required to be opened out last winter, another method, or rather another modification of longwall was introduced, by which the two seams are extracted practically by one working. The mode of procedure will now be described:

The section of the seams and their immediate strata is made up as follows: Lower seam (5 ft. thick) intersected at 3 ft. by a 6-in. band of shale, then 9 in. of inferior coal which is left and forms the roof of the lower seam. Above this is 2½ ft. of stony fireclay, on which rests the upper seam (3 ft., 6 in.) capped by

props, and a 2-yd. packwall at 6-yd. intervals. The lower seam is taken out in juds or lifts of 2½ yd. each. The packwalls are built in position immediately there is room; the three rows of props, which are farthest down in the goaf, are withdrawn; the inferior coal and fireclay then falls leaving the upper seam exposed to view, and unsupported, except by the packwalls and one or two props. We then at once climb on the fallen dirt, make it as level as practicable on its surface and set two or three rows of props to support the upper seam, placing flat pieces of wood under the props in addition to a broad cap at the head, to make them thoroughly secure.

MINING THE UPPER COAL

We next commence to cut down the up-

per coal, beginning down the pack side and cutting up to within a few inches of the sod overlying the seam. We find it much the better plan to leave 4 to 6 in. of coal and prop to it, as the sod is of a very tender nature and causes a serious loss of coal if it falls and mixes with it.

Twelve stamps to be installed at the West Rand Consolidated Company will be the heaviest on the Witwatersrand (*Aust. Min. Stand.*, Dec. 30, 1908). Each stamp will weigh 1850 lb. and have a duty of 12 tons per 24 hours.

*Abstract of an article published in *Mining Engineering*, February, 1909.

Data on Coal-mine Ventilation

Mine ventilation is a subject which has received a great deal of attention during the last few years, largely due to the fact that mines have increased in depth and in extent far beyond the original plans.

Small mines and those worked on a minor scale, could be ventilated by natural air currents, but the air shafts for natural ventilation must be large on account of the low velocities of air. As the mines increased in extent and depth, shafts were entirely too small for natural ventilation, and it became necessary to use mechanical means; in fact, without a mechanically driven fan it is impossible to get sufficient air through the extensive workings. While there is always a certain amount of natural ventilation, probably less than 25 per cent. of the total volume of air current is due to natural flow; the rest must be furnished by the fan.

ADVANTAGES OF THE SMALL HIGH-SPEED FAN

The large volumes of air require a fan of great capacity, which may be obtained by a wheel of large diameter operating at low speed or by the higher speed of a smaller wheel. The small high-speed fan possesses many advantages. With a large low-speed fan an increase in volume is obtained at a speed which is liable to be detrimental to the construction of the heavy wheel, and the large fan is expensive to run for small volume. The small high-speed fan may have the speed increased without danger, for it is built for such service, and when run at reduced speed the cost of driving is not great. Again, the parts of a small high-speed fan are of less weight, and consequently more easily handled—important factors in installation and maintenance costs.

The driving of mine fans is a matter of importance. With a very large wheel making 30 to 60 r.p.m., direct-connection to motor or engine is out of the question; however, with a smaller fan running at 175 to 350 r.p.m. a powerful reliable set is obtained, especially for water-gages up to 5 in., by driving direct-connected.

The weight and dimensions of such apparatus are very moderate, and the efficiency of the set is high, for the engine or motor may be run at its most economical speed.

The Sturtevant centrifugal fan of the multivane type, is especially applicable for the ventilation of modern mines, for it is essentially a high-speed, large-volume fan. The manufacturers claim that this machine can be run at a higher speed with safety and economy than any other fan of the same capacity. It is a thoroughly up-to-date design for handling large volumes of air against resistances up to 5- and 6-in. water-gage.

The multivane type of wheel is made up of 60 or more shallow blades which are

spooned to distribute equally the air pressure within the fan, and to increase the strength and rigidity of the wheel. The shallow blades permit large inlets, which contribute to high efficiency, because the friction loss of the entering air is a minimum. With a fan wheel of but few blades, the inlets cannot be as large if the necessary blade area to give the volume is maintained.

DETAILS OF FAN CONSTRUCTION

The substantial cast-iron hub or hubs are strong and of sufficient size to receive and hold rigidly the steel arms of T section which are cast therein, and securely riveted at the extremities to the fan blades. For the large wheels two or more sets of arms are used to secure greater rigidity.

The shaft is extra large to support the

the fan outlet and measured in inches of water. For exhaust systems the fans require less horsepower to maintain a static suction at the fan inlet equal to the value given, and handle less air. This is due to the fact that in the blow system no allowance is made for the conditions existing at the inlet, while in fact a suction exists there.

For a given volume of air blown into the mine, the static pressure maintained at the fan outlet is that pressure caused by the various losses due to the resistance to air flow in the circuit, whereas with an exhaust system the static suction maintained at the fan inlet is that caused by the various losses in the air circuit added to the suction which exists at the fan inlet (but not taken account of) in the blow system.

When economy is not essential, or in case of emergency, these speeds may be materially increased, resulting in much greater volumes. If less volume is desired than given above, the wheel and housing may be of one-half the width, giving practically one-half the volume and requiring one-half the horsepower.

wheel without deflection, and special attention is given the bearings so that there will be no occasion for shut-downs. The wheel is carefully balanced to eliminate vibration. Usually the fan is of the type known as ¾ or ⅝ housing to reduce the height of the shaft above the foundation, and is built of steel plate rigidly braced with steel angles and fastened to foundations of brick or concrete, of which material the inlet housings also are made. To secure a large volume without increasing the diameter of the wheel and consequently the height of the fan, the housing and the wheel are usually made of double width. The small diameter also makes it possible to run the wheel at a speed suited to direct connection to engines, or electric motors.

The accompanying table gives the performance of Sturtevant mine fans for use for systems where air is blown into the mine; in other words the stated resistances are the static pressures existing at

Broken Hill Proprietary Company

In the last semester the zinc concentration plant treated 135,235 tons of material, producing 29,659 tons of zinc concentrate, averaging 15 oz. of silver per ton, 9½ per cent. lead and 44 per cent. zinc. Finer grinding by means of tube mills, as compared with ball mills, increased the extraction. The Port Pirie smelter treated 123,784 tons of ore, producing 48,350 tons of bullion. The refinery treated 48,368 tons of bullion, producing 2,589,476 oz. of silver, 1054 oz. of gold, 47,833 tons of desilverized lead and 470 tons of antimonial lead. Gas firing in connection with the roasting furnaces has given satisfaction. The first zinc distillation furnace has been completed and nine more are to be erected. Suitable clay for making the retorts has been discovered in the vicinity. It is expected that eight furnaces will be in operation by the end of 1909.

Present Position of the Steel Rail Question

The new specifications for rails issued by the larger lines include chemical requirements for open-hearth rails, and the orders are usually for as large a tonnage of this grade of steel as the mills are prepared to supply within the time limits. The growth of the open-hearth rail manufacture in the United States has been rapid. In 1903 only 45,000 tons were rolled. In 1907 the amount rolled had increased to 252,000 tons, and in 1908 to 567,000 tons. The bessemer rail production reached its maximum in 1907 when 3,380,000 tons were rolled, while in 1908 it was the smallest since 1897, less than the average for the 10 preceding years, and only 1,354,000 tons. The open-hearth rails rolled in 1908 equaled 42 per cent. of the bessemer. The present capacity of the steel works in the United States for the manufacture of open-hearth rails, including the new Indiana Steel Works just going into operation, is nearly 2,000,000 tons, or about 50 per cent. of total new-rail requirements in prosperous years.

THE PENNSYLVANIA SPECIFICATION

The new Pennsylvania specification makes no change in the chemistry for bessemer rails, but adds a second classification in the chemistry of open-hearth rails. The previous specification of April, 1908, made 0.03 phosphorus and 0.80 carbon the upper limits, while the new one makes the upper limits for Classification A, phosphorus 0.03 and carbon 0.083; for Classification B, 0.04 phosphorus and 0.75 carbon. The desired carbon for the two grades is 0.75 for the lower phosphorus, and 0.70 for the higher, thus following the general law that for each 0.01 per cent. phosphorus added the carbon should be reduced 0.05 per cent. on account of the brittleness due to excessive carbon and phosphorus. The reason for making two classifications for open-hearth rails relates principally to the cost of manufacture. It was thought desirable to specify phosphorus as low as 0.03 so that high carbon could be used and the wearing quality of the rails, particularly on curves, would be materially improved. But the extra time required in the open-hearth furnace to reduce phosphorus from 0.04 to 0.03 results in some increase in the cost of manufacture, and a slight addition to normal price per ton is added for the Class A rails.

A clause has been added which excludes ingots that have been so overheated that the scale on the sides becomes liquid.

The requirements under the drop test are less rigid than those of the previous specification, and some concession has been made to the manufacturer in this

particular which is not likely to insure better rails so far as the brittleness of bessemer rails is concerned. The former requirement was that "if a test piece breaks under the drop without showing physical defects all rails made from that heat shall be rejected absolutely." The present provision permits of a retest after failure of the first, allowing two more pieces from the same heat to be tested, and if neither of these fails the rails are accepted as No. 1 or No. 2, according to the deflection. If either of the second test pieces fails all rails from that heat will be rejected. The provision that drop testing shall be continued to the destruction of the specimen in case the first piece breaks without showing physical defects, is an added precaution which should result in a material benefit to the railway by reducing the number of piped rails which, in spite of the usual inspection and tests, get into the main track. This new feature in drop testing has been obtained by some concession to the railmaker, as it is agreed that if the test piece does not break under ordinary conditions, but when nicked and tested shows pipe, the top rail from each ingot will be accepted as "special" rails, and marked differently. These rails will be regarded as inferior and not used in main-line track. For open-hearth rails it is required that makers shall furnish inspectors with complete chemical analysis for each melt.

THE BALTIMORE & OHIO SPECIFICATION

The new Baltimore & Ohio specification for bessemer rails, dated Jan. 25, 1909, is similar to the Pennsylvania in chemical requirements, but for open-hearth the chemistry is somewhat different. The upper limit for phosphorus is made 0.04 for all rails made by that process. Manganese is allowed as high as 1 per cent. and carbon 0.80 per cent. This specification also allows retests. It provides that drop tests shall be made of two test pieces of rail rolled from the top of different ingots, and if either fails a third piece shall be tested. The new Pennsylvania railroad specification requires the drop-test pieces to be cut from the rail bar next to either end of the top rail. The Baltimore & Ohio also requires the drop test to be carried to destruction so that an examination can be made of the fracture and pipe or other interior defects can be detected; and acceptance of the rails is based on the clean fracture as well as the amount of deflection. The effort to enforce the discard of a certain per cent. of high of ingot to eliminate segregation appears to have been abandoned and the new specifications now simply require that there shall be sheared from the top of the ingot sufficient discard to insure sound rails.

CANADIAN RAILS

The Canadian Pacific has prepared a new specification for rails which is interesting because it is intended to meet the

severe winter conditions of Canada where the track is frozen rigid for long periods. It was prepared also with special reference to the conditions of rail manufacture in that country. Two rail mills in Canada have a capacity about equal to the ordinary requirements of Canadian railways. The Dominion Iron and Steel Company at Sidney, N. S., manufactures basic open-hearth steel only. The product of the Algoma Steel Company at Sault Ste. Marie, Ont., is 75 per cent. acid bessemer and 25 per cent. basic open-hearth. The bessemer rails have only 0.085 phosphorus and the average carbon is 0.58 and for open-hearth steel the upper limit for phosphorus is 0.06 and the lower limit for carbon 0.60. The standard section for new rails on the Canadian Pacific is 85 lb., and this is preferred to the 100-lb. rail on account of the unfavorable experience due to square breaks with the 100-lb. rail having American Society of Civil Engineers section. This decision is based upon the fact that the 80-lb. section, having identical chemical composition under the same traffic and like climatic conditions, did not break as frequently. The Canadian Pacific has in track now 85,000 tons of the new 85-lb. rails. In their manufacture it was found that when they approached the saw they were of more even temperature in all parts of the section, the rail head being cooler than in the old section. Therefore, a finer grain of steel was produced, having better wearing qualities. The more equal distribution of material between the head and the base simplified the cold straightening to such an extent that it required 40 per cent. less work than the old section with its thin flange and thick head. The straightening of the rails under the cold press seriously impairs their strength and is one of the principal causes of fracture. If the 100-lb. rail had been given the advantage of a better balanced section it also could have been rolled with a cooler head and would have required less cold straightening and given better service.

The Canadian Pacific drop test for open-hearth rails is more severe in most of its provisions than those already mentioned. It requires that from each 50-ton heat three rail butts shall be tested, and each butt must be taken from the top end of the first, middle and last ingots cast of each heat. The supports are 4 ft. apart and the height of drop is 20 ft. for the 85-lb. section. If two of the test pieces are not broken and show a deflection of less than $\frac{3}{16}$ in. the heat is accepted. If two fail it is rejected. There are no retests, and less is left to chance than is in most of the rail specifications used in the United States. The practice as to discards in Canada also appears to be more definite and satisfactory than in the United States. After cutting off sufficient to square up the end, at least 12 in. more of seemingly solid steel is cut from that end of the bloom, and if the steel does not then look solid the cutting must continue until it

*Abstract of article in the *Railroad Age Gazette*, New York Chicago, March 19.

does. In the same specification the drop test for bessemer rails is 18 ft. and the minimum deflection $3\frac{1}{4}$ in. A rail butt from every third heat is taken from the top end of the first ingot. If it fails a second test is made and if that fails all rails made from that heat are rejected.

OTHER SPECIFICATIONS

The Santa Fé received last year a supply of open-hearth rails from the Bethlehem Steel Company, and they were among the first rolled by the new mill. The specification required 0.04 phosphorus and 0.60 carbon. The section is a special one having a weight of 85 lb. per yard.

The Burlington has ordered a large tonnage of open-hearth steel and adopted the 90-lb. section, Series A, recommended by the American Railway Association. Its specification requires that there shall be sheared from the end of the bloom formed from the top of the ingot 9 per cent. discard, or until sound metal shows on the end of the sheared section. "The chemical composition shall be within the following limits: Carbon, 0.55 to 0.65; manganese, 0.75 to 1; silicon, not to exceed 0.20; phosphorus, not to exceed 0.06. For every point (0.01) phosphorus is reduced below 0.06, carbon may be increased four points (0.04), the maximum carbon to be 0.80." The requirements in the drop test provide that at least two test pieces shall be selected from each heat by the inspector, and the height of drop for the 90-lb. rail is 19 ft. If the first test piece breaks then two others from the same heat are tested and if either of these fail all the rails from that heat are rejected. If both meet the requirements, then the rails from that heat will be accepted. It is also provided that rails shall not vary throughout their entire length more than 5 in. from a straight line in any direction when delivered to the cold straightening press. Those which vary beyond that amount are classed as second-quality rails.

PIPING

Inspectors using the new Pennsylvania rail specifications have discovered quite a large percentage of piping. Testing to destruction discloses such piping even in the tests that had failed to break under the drop, thus clearly indicating that there must have been a large number of piped rails delivered to the railway companies under former practice. The railmakers have been much disposed to contradict the possibility of a large percentage of piped rails existing; in fact, have in many cases taken the position that undue stress had been placed upon that defect. Some authorities, for instance, have argued that with many failed rails the defects which have been classed as pipes have really been caused by the presence of slag which, under the strain of traffic, had acted as a wedge splitting the steel. While that may have happened in some cases, many failures causing accidents have been due to

pipes, and some method of inspection should be used to detect them.

GENERAL PROGRESS MADE

In conclusion, it is evident that the rail question in general is in an experimental stage, but making satisfactory progress toward improved standards. The new sections with a heavy base having a larger area than the head, have already shown important results in reducing cold straightening and in producing a finer steel structure due to cooler rolling. The open-hearth steel, with phosphorus less than half that in bessemer, will largely reduce rail breakages due to brittleness. The drop tests must be readjusted to suit the testing machine with a standard anvil and definite foundation. The one important matter which remains unsettled and indefinite is that relating to discard, segregation and the other items which affect

Feldspar Mining in Ontario

By CAJETAN MORSACK*

In various portions of the Province of Ontario there are extensive ridges of feldspathic rock. Frequent outcroppings make it possible to trace these ridges for many miles. In texture the rock ranges from a coarse-grained granite to a rock consisting of little else than pink or white feldspar intermixed with some quartz. Among these ridges are found valuable deposits of feldspar, such as are being mined at present in Frontenac county, more particularly in Laughborough, Bedford and Portland townships. For profitable mining the deposit must be large, easily mined, reasonably free from impurities, and so situated as to be readily brought to the mill.

STOPE AND HOISTING ARRANGEMENT, RICHARDSON MINE, BEDFORD TOWNSHIP, ONTARIO

NATURE OF THE DEPOSITS

The feldspar occurs in more or less distinct veins in the Archean gneissoid granite, with usually a capping varying in thickness from a few inches to many feet. This capping is more often a granite or "feldspar rock," but in some instances is a hornblende or mica schist. Accompanying the feldspar there may be distinct veins of practically pure quartz which extend above the spar and may form part of the capping material. These veins of quartz are usually quite large, from 1 to 10 ft. wide, and varying in depth. The vein of feldspar varies in widths from a few feet to 40 or 50 ft., or even more in exceptional cases. Few mines have been worked to the bottom of the deposit, but a depth of 50 ft. has been attained at the Richardson mine with ore at the bottom.

*Superintendent, Verona Mining Company, Verona, Ontario.

Rhodesian Gold

Gold production in Rhodesia in February is reported at 45,744 oz. fine, a decrease of 2877 oz. from January. For the two months ended Feb. 28 the total was 94,365 oz., or \$1,950,566. This is a decrease of \$79,311, as compared with the corresponding period last year.

The veins of feldspar cross the strike of the mica schists and granites in which they are found more or less obliquely. Sometimes two or more veins having different directions will intersect. Some are very irregular in outline while others run in practically a straight line for several hundred feet with sharply defined vertical walls. Usually the vein may be traced quite readily by the depression between the granite walls, since the latter almost invariably rise to a greater height than the vein material, a natural consequence of their greater resistance to weathering.

The criterion of good feldspar is its crystallization, luster and perfect cleavage. Spar containing free silica, or what the miners call "sandy spar," must be rejected. Usual impurities are quartz, mica, hornblende, tourmaline, and pyrite. Of these pyrite usually occurs in seams in the spar or occasionally in small pockets. Mica, tourmaline and hornblende occur in well defined crystals through the spar. The last two have received from the miners the name "black jack." The veins are without doubt segregations. The mineral is usually orthoclase, or the pink sodal-orthoclase perthite, consisting of inter-laminated orthoclase and albite. The presence of a good body of clear flint or quartz is usually taken as a healthy indication of the absence of any great quantity of the mica, pyrite and other basic impurities.

METHODS OF MINING

Feldspar deposits of this region are all mined by open cut. The soil is at most not more than three or four feet deep. This is stripped off, the capping removed, and the spar mined by stopes, usually 10 or 12 ft. to a stope. At the Freeman and Bauder mines the ore is hoisted in wooden buckets and dumped upon a pile, later to be hauled by teams to the railroad. At the Richardson mine, as shown in the accompanying illustration, the ore is hoisted by means of a cable to the top of the hill, where the buckets are loaded directly upon special mine cars operating on a self-acting incline by means of which they reach barges and are towed across the lakes to the railroad.

On account of its perfect cleavage the feldspar is easily mined, as it breaks readily into nearly rectangular prisms of practically a uniform size. These are shoveled into the buckets, and usually there is one man for each bucket who picks out any refuse or impure material. Formerly the ore was "forked" but this practice has been almost wholly abandoned. Where a good body of pure white flint is encountered this is saved and sold for use as a flux.

Drilling is done almost entirely by steam. As yet no drifting has been done, and whether this is practicable where the capping is very thick is problematical on account of the ease with which the spar is shattered. This would also mean a

change in power on account of the ventilation problem.

Where it pays, the impure material is cobbled, but on account of the low price of the product and the relative high cost of mining and transportation, spar which needs constant cobbling cannot be mined at a profit. Little trouble is had with water. In most cases there is scarcely more than enough to supply the boilers.

TRANSPORTATION AND COSTS

The serious difficulty in mining feldspar deposits in this section is transportation. The distances around the lakes are so great that no attempt is made to haul in summer. In winter the frozen lakes and swamps afford a good level road for the greater part of the distance. The lakes are valuable assistants in the haulage at the Richardson mine. It may be readily seen how largely the cost of transportation enters into the total cost of production where this item alone ranges from 45 to 80c. per ton, depending on the distance. In some cases where it is feasible the ore is taken by boats across the lakes to some point on the railway, thus affording a cheaper method of transportation.

In this section the cost of mining runs from \$1.10 per ton loaded on the cars at the most favorably situated mines, to as high as \$2.75 per ton at smaller mines less favorably situated. It is obvious that one problem needing serious attention is that of transportation to railway points, and where the deposit is of sufficient importance to warrant it, this is being more thoroughly looked after.

Practically all the feldspar from this region is used in the pottery industry, hence the desirability of keeping out iron compounds as these produce yellow or brown spots on the finished ware.

Boston Consolidated Mining Company

The Boston Consolidated Mining Company, in its fiscal year ending Sept. 30, 1908, produced from its Sulphide mine 79,300 tons of ore containing 7447 oz. gold, 55,795 oz. silver and 3,459,911 lb. of copper. The cost of mining, including development, was \$183,092; transportation to smelter, \$13,613; smelting, \$217,049; freight and refining charge on bullion, \$60,188; total, \$504,841. There was deducted for losses in smelting and refining 240,880 lb. of copper and 6573 oz. of silver. After crediting value of gold and silver, the cost of the copper delivered at New York was 10.22c. per lb. At the Porphry mine, the first shipment of ore mined by steam shovel to the Garfield mill was made on Jan. 15, 1908. As the shovels removed the capping they exposed an unlooked-for grade of ore, satis-

factory as to copper content, but high in iron pyrites, which greatly reduced the ratio of concentration. Underground development subsequently proved that not over 16 per cent. of the payable orebody is included in this class of iron ore. Steam-shovel work was gradually suspended as the ore became available from underground working. During the year 411,175 tons of stripping were removed at a cost of 17.72c. per ton. The amount of ore mined by steam shovels and shipped to the Garfield mill was 26,647 tons. Meanwhile, underground developments were made with a view to the inauguration of mining by the caving system. In the course of this development work 128,391 tons of porphyry ore were obtained. The first section of the Garfield mill was put in operation on January 27, 1908. Only four sections were operated until September, 25, when four more were put to work. The mill recoveries ranged from 70 to 72 per cent., and milling cost was reduced from a maximum of \$1 per ton experienced in the first few months of operation to 47.2c. per ton in September. The total cost of the mill to date is \$1,568,604. The mill treated 143,284 tons of ore, producing 9935 tons of concentrate, containing 397 oz. of gold, 4967 oz. of silver and 2,037,599 lb. of copper.

Sidney J. Jennings, consulting engineer to the company, made a report under date of Dec. 1, 1908, in which the states that the Porphry mine has 27,889,000 tons developed of ore averaging 1.52 per cent. copper, besides 9,550,000 tons averaging 1.23 per cent.

He estimates that the ore will be mined by steam shovels for 31c. per ton and by the caving system for 70c. Both methods will have to be employed. The capacity of the mill is estimated at about 1,000,000 tons per annum. Ratio of concentration will be 13 to 1 and the concentrates will assay approximately 14.4 per cent. copper.

On the supposition that one-half of the ore will be mined underground and one-half by steam shovels, the cost of production will be as follows: Mining, 50.5c. per ton; transportation to mill, 28.7c.; milling, 40c.; smelting and refining charges, 70c.; general expense 10.2c.; selling commission, 3c.; interest on bonds, 10.3c.; total, \$2.127; this cost will decrease as the proportion mined by steam shovels increases. The recovery of copper from the average ore should be 10.5 lb. per ton. and the cost delivered at New York with allowance for gold and silver, 10.5c. per lb. Up to Sept. 30, 1908, the company had expended a total of \$3,078,490.83, of which \$135,107 was for porphyry developments; \$488,484 for steam shovel development; \$1,600,483 for Garfield mill and shops; \$91,068 for steam-shovel equipment; \$136,028 for steam-shovel railway; \$80,800 for gravity tramway; \$137,758 for railway extension.

Delaware, Lackawanna and Western

The Delaware, Lackawanna & Western Railroad Company, besides a system of railroads extending from New York to Buffalo and Oswego, owns a large coal estate in the anthracite region in Pennsylvania. The company—unlike most of the anthracite-carrying companies—operates its coal properties directly, and not through the medium of a subsidiary corporation. The report is for the calendar year 1908.

The Coal Department statement of tonnage for the year is as follows, in long tons:

	1907.	1908.	Changes.
Stocks, Jan. 1.....	602,939	590,089	D. 12,850
Mined and bought 10,371,341		10,314,359	D. 56,982
Total.....	10,974,280	10,904,448	D. 69,832
Coal sold.....	10,384,191	9,610,127	D. 774,064
Stock, Dec. 31.....	590,089	1,294,321	I. 704,232

Coal sales, with the average prices realized, were made up as follows in 1908: At mines, 101,057 (average \$2.32 per ton); company's supply, 1,377,708 (\$0.98); local agencies, on line of road and at tide, 5,789,685 (\$3.75); foreign agencies, off line of road, 2,341,677 (\$0.35); total, 9,610,127 tons, at an average of \$3.07 per ton.

The income account for the year may be stated as follows:

	Tons.	Amount.	Per Ton.
Coal sales.....	9,610,127	\$38,185,417	\$3.97
Increase in stock.....	704,232	1,413,493	2.01
Total receipts.....	10,314,359	\$39,598,910	\$3.84
Coal mined & bought 10,314,359		\$17,063,069	\$1.65
Transportation.....		14,318,780	1.71
Co's line.....		8,888,315	
Transportation.....		2,415,897	0.73
Handling and selling.....		7,933,179	1.39
Improvements.....		252,828	0.02
Taxes.....		390,500	0.04
Total expenses.....	10,314,359	\$36,432,117	\$3.44
Net earnings.....		\$ 4,166,793	\$0.40

Disregarding the coal added to stock, which is credited at cost price, the profit on coal sold was 57c. per ton. The cost of coal at mines was 48.2 per cent. of expenses; transportation, 46.1; handling and selling, 3.9; mine improvements, 0.7; taxes, 1.1 per cent.

The report of the railroad shows coal carried as follows: Anthracite, 9,971,061 short tons; bituminous, 1,018,872; coke, 95,156; total, 11,085,089 tons, a decrease of 624,029 tons. Of the total earnings of the railroad 43.7 per cent. came from the transportation of coal. The average haul on coal in 1908 was 190 miles; the average rate received 0.861c. per ton-mile. The coal rate was 0.153c. per ton-mile greater than that on merchandise traffic.

The report says: "The results of the coal operations, while not equaling those of 1907, are gratifying, in view of the widespread business and industrial depression. The cost per ton of mining and preparing coal for market was higher than in 1907. As heretofore explained, this yearly increase in cost, due to physical conditions,

is a feature of the industry common to all mining companies, and is a matter of importance and interest to all consumers of anthracite.

"The company's mining operations were conducted throughout the year with success and were remarkably free from accidents of a serious character, for which much credit is due to all connected with these operations. The expenditures made for improvements of an extraordinary nature were somewhat less than in recent years, but were ample to maintain the mining properties in a high state of efficiency and in condition, as to new development, to increase the output of coal from them sufficiently to meet to a reasonable extent increased market requirements.

"The total coal sold during the year was less by over 700,000 tons than during the previous one. As the tonnage produced and bought was substantially the same as in 1907, the decrease in sales is represented by the larger stocks of coal on hand at the close of the year, which about equaled the decrease in sales. Of the increased stock of coal on hand a larger percentage was of the small or steam sizes than is ordinarily the case. This was owing to the marked depression in the industrial activities of the year. The reduced quantity of anthracite coal used by the company itself also contributed to the accumulation of small sizes thereof on hand at the close of the year.

"The prices of anthracite coal established in 1902 have been generally well maintained in all markets throughout the year and the industry continues on a steady, healthy basis.

"The accumulation of stocks of coal before referred to, which is general with all the companies interested, is not considered alarming by them, in view of the fact that on March 31 the existing arrangement with the mine employees, under which wages were fixed in 1906, will expire by limitation and there is a possibility that, as in 1906, the miners may suspend work pending the outcome of future negotiations. Should there be such suspension of mining operations, it will be readily seen that the accumulated stocks of coal will be required to amply protect consumers, pending the resumption of work.

"The company's mine employees have been prosperous and apparently contented during the past year. They certainly have suffered less from the depression of general business than any other important class in the country. This fact, however, does not seem to have in the least influenced the leaders of the labor organization with which they are chiefly identified as respects the character and extent of the demands they have decided to make for increased wages and other concessions from their employers, the anthracite companies. For the most part these demands are the same as were urged before the Anthracite Strike Commission in 1902 and were, after full hearing, denied by it as

being unjust and unreasonable. The conditions at present existing are not changed to any extent from what they then were, nor can there be any reasons now urged why these demands are more reasonable or just now than then, and they cannot, therefore, be seriously considered.

The important question of whether this company, in common with others similarly situated, may continue to own and operate coal properties, and mine, purchase, transport and sell coal in the future as it has during the past 50 years, although forbidden to do so by the so-called "commodity clause" of the Interstate Commerce law, is now pending before the United States Supreme Court on appeal taken and argued recently from a decree of the Circuit Court of Appeals, which in a case brought by the Government to test the legality of the act, confirmed the right of the company to continue its coal business as heretofore. It is confidently expected that the Supreme Court will affirm this decision."

Brazilian Monazite

Monazite sand from the interior of Brazil contains from 4 to 5.7 per cent. of thorium oxide, while that from the sea coast may contain as much as 7 per cent. Brazilian monazite is magnetic, which fact renders it easy to clean. It has been found in commercial quantities only in alluvial deposits in the States of Rio de Janeiro and Minas Geraes and along the coast, from Rio to Bahia. Its original occurrence is in certain felspathic rocks, pegmatite, syenite, and gneiss, in which it constitutes from 0.07 to 0.2 per cent. of the weight. The present deposits have been derived by erosion and concentration of such rocks.

The interior deposits are found in the beds of dry water courses in the form of gravel and sand containing not more than 2 per cent. monazite, together with quartz, garnet, ilmenite and other heavy minerals. The deposits sometimes lie on the surface, and sometimes under a bed of clay as much as 3 m. thick. The sand is mined and concentrated roughly, and is finished on electro-magnetic machines, which make a 95 to 96-per cent. monazite product containing, on the average, 3.7 per cent. thorium oxide.

The early development of the beach deposits by Gordon, and the subsequent retraction of his concession by the Brazilian government, which had not been aware of the value of the deposits as a source of revenue, is well known. The government has even considered the possibility of establishing a chemical manufacturing industry for the preparation of thorium nitrate within its own boundaries, and it is reported that the State of Santa has granted a mining concession to Israelsohn & Co., with this object in view.

The Coal-Mining Situation in Indiana

The national executive board of the United Mine Workers of America will convene in Indianapolis, Ind., March 24. The meeting is called to consider general conditions in the coal-producing States, including Nova Scotia. There is a probability of a clash between the Indiana operators and the miners over the 3/4-in. drill-bit law passed by the recent legislature. It is stated the operators will refuse to sign a wage scale for next year until the miners have agreed not to demand the large bits, and as a large proportion of the men desire to use bits, a stubborn controversy is likely.

It is claimed by the operators and affirmed by James Epperson, mine inspector, that the legislature by enacting the law, crippled the coal industry in Indiana more than it thought. Under the former law prohibiting the use of the large bit, the industry of the State made greater progress than at any time in its history. The reports for 1907 and 1908 show that the miners of Indiana made more money, produced more coal and had altogether better years than they had ever before experienced in the history of Indiana coal mining. There were fewer accidents and deaths from accidents than ever before, which is attributed to the use of the smaller bit and rigid enforcement of the mining laws.

The new Indiana law permitting the use of the larger bit is dangerous, and while the controversy is on, it is significant that five men were killed March 19 by a windy shot which occasioned an explosion in the Sunnyside mine near Evansville. The disaster was due to an extra large charge made possible by the use of the large drill. The operators are hopeful of inducing the men to forego the privilege of using the larger bit from both an economic and hazardous basis.

James Epperson has been reappointed State mine inspector for Indiana by State Geologist W. H. Blatchley. Mr. Epperson has already begun an agitation for an "oxygen helmet" station in Terre Haute, the most central point in the bituminous field. It is his purpose to have the operators of the field join in the purchase of six or more of the helmets, and to have the city of Terre Haute supply the station. The helmets are sold at \$250 each.

WOULD PREVENT LOSS

The interest of the operators is attracted to the helmet because it is considered an economical appliance. According to the statistics in the office of the State mine inspector, scarcely a day passes that there is not a bad mine fire somewhere in the State. These fires last for weeks in most instances, always causing a cessation of work in a part, if not all, of the mine.

"As a rule," said Mr. Epperson, "the heat from these fires is not so great as to prevent the miners from going to the places where the fire is burning, but the gases generated keep them back. By means of the helmets the men could go to the seat of the fire and be able to cope with it. Thousands of dollars annually could be saved by the operators by means of the appliances."

"By establishing a substation in Terre Haute," said Mr. Epperson, "and equipping it with a half dozen or more of the helmets, we would have them within an hour's journey of all the big mines of the Indiana field. By special arrangements with the steam and electric railroads, even this time could be shortened. My plan is to construct a gas tank in the station, where the operators and miners may be shown that there is absolutely no danger connected with the use of the appliance. After these demonstrations I would have the United States Geological Survey send men to the district to instruct the mine superintendents and fire-bosses in the use of the devices."

Mr. Epperson donned one of the helmets at the Urbana station and worked in a glass tank of deadly gases for several minutes.

"A man could don one of those devices and dig coal," he said. "The only handicap is the 35 lb. of weight added."

Colliery Notes

It is a good rule to require that no holes shall be charged for a longer period than 30 min. before being fired.

It is generally advisable to have a rule forbidding the firing of any shots until the face is either sheared, mined or undercut, not less than 3 ft. deep. It is also best to prohibit the firing of any shots when the bore holes used for firing extend beyond such undercutting or open end.

Experience continues to demonstrate that 6 per cent. of the value of a coal company's plant and equipment is necessary to fully maintain its efficiency, and either replace the investment in cash, when exhausted, or in kind, in new mining territory when needed, without further capital provision being necessary; and until so used the credit remaining should continue available for working capital.

The best opinion advises against the practice of having two shafts connected together by a wooden arrangement on the surface. When the two shafts are connected, a fire in one is then easily communicated to the other shaft. It is probably true that at a majority of our coal mines, the downcast and the upcast shafts are connected on the surface by gangways of wood. Our laws do not forbid this practice; however, it is a point that should be considered by mine operators in building new plants.

For draining underground workings, located a considerable distance from the shaft, nothing is more suitable than the three-throw electric-driven ram pump; the machine should be designed to keep the velocity of the water on the suction side down to 3 ft. per sec., and the velocity in the delivery pipe should never exceed 6 ft. per second. In this connection it should be remembered that it is better to keep the plunger and valves large, and the stroke short, with a higher speed, in preference to a long stroke and a slow speed.

Before the Société de l'Industrie at Paris recently, M. Siegler stated that at a coal mine in the Loire district, France, the cost per ton of producing coal in 1855 and 1907 compared as follows:

	1855	1907	Increase
Labor underground...	\$0.59	\$0.95	\$0.36
Labor on surface.....	0.12	0.26	0.14
Supplies	0.25	0.79	0.54
Total mining cost...	\$0.96	\$2.00	\$1.04
General expenses.....	0.51	0.68	0.15
Total	\$1.47	\$2.66	\$1.19

The average quantity of coal per miner per year had not changed, being about 230 tons in each year.

There are many precautions to observe when a heading is approaching old workings. Besides keeping a center bore-hole 25 or 30 ft. in advance and flank bore-holes about 15 ft. ahead, there should be preparations to deal with any water or gas that may be encountered. A good supply of dry fir plugs, 4 or 5 ft. long, should be provided and when water is tapped, one of these plugs should be driven tightly into the hole, and a post wedged up in front to prevent the water pushing it out. It is also sometimes advisable, when there are signs of water percolating through into the hole, to insert a pipe with a valve through which the boring rods may be passed and the boring continued. As soon as the water is tapped the rods may be withdrawn and the valve closed thus preventing the sudden inrush of the water.

At one of the mines in southern West Virginia, where the coal seam is situated high in the mountain, a modern aerial wire-rope tramway is used to advantage. The tramway crosses a river and runs to a loading station near the top of the mountain; it has a clear span of 1300 ft. The buckets travel at the rate of 300 ft. per minute, and make the entire distance in about 4 minutes. The difference in elevation between loading and discharging stations is 360 ft., which permits the tramway to be operated by gravity. The speed is controlled by two brakes at the loading station. The tramway handles 800 tons a day and requires the services of two men at a total cost of \$4 per day; this makes the cost of transporting coal over this system 1/2 cent per ton for labor. It is stated that the same labor could handle practically double the present tonnage by adding more buckets.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, President and Treasurer. ROBERT MCKEAN, Secretary.
 305 Pearl St., New York.
 London Office: 6 Bonnerie Street, London, E. C., Eng.
 CABLE ADDRESS: "ENGINEERING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs. Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue. For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.
 Our circulation for March, 1909, was 42,000 copies.
 April 3..... 13,000
 April 10..... 10,000
 None sent free regularly, no back numbers. Figures are live, net circulation.

Production of Lead in the United States

Reports from all of the smelters and refiners show that the production of refined lead in the United States in 1908 was 413,868 tons as compared to 426,146 tons in 1907. Details of the production are given in the subjoined table, which shows the production of Missouri and Kansas lead according to groups of smelters, the single smelter in Kansas being included in "Southwest Missouri," and the two smelters in Illinois, near St. Louis, in "Southeast Missouri." The lead that is entered as "desilverized" is the production of desilverizing refiners other than those included in the two groups above mentioned. The present conditions of lead smelting in the United States do not permit of any accurate, and at the same time rational, classification.

PRODUCTION OF REFINED LEAD.

Class.	1907.	1908.
Desilverized.....	213,383	187,759
Antimonial.....	9,614	a
Southeast Missouri.....	108,510	113,103
Southwest Missouri.....	17,833	18,014
Miscellaneous.....	790	
Total domestic.....	350,130	318,876
Desilverized, foreign.....	76,016	94,992
Grand total.....	426,146	413,868

(a) The production of antimonial lead in 1908 was 13,109 tons; in the above table it is included with the lead entered as desilverized.

The above statistics include a considerable quantity of lead refined from scrap and old metal, which is reworked by several of the refiners whose principal business is the refining of base bullion of virgin origin. There is, moreover, a considerable production of lead by smelters who make a business of reworking old metal only. To some extent they market their product as pig lead, and to some extent they refine it as an alloy, which is marketed. It is difficult to draw the line where statistical enumeration should cease in this respect. In 1907 the production of such reclaimed pig lead was 9990 tons, while the production in the form of alloys was 15,508 tons. In 1908 the production of pig lead from old material was 14,323 tons. It is probable that the reports of this industry are incomplete both for 1907 and 1908.

The statistics of lead of foreign origin as reported by the refiners do not agree exactly with the reports of imports by the Bureau of Statistics of the Department of Commerce and Labor, which in 1907 entered the importation of lead in ore and base bullion as 70,537 tons; and in 1908 as 109,286 tons. The discrepancy

in 1907 is partly accounted for by the item of antimonial lead, which is recorded in the above table as wholly of domestic origin, whereas a large part of it was doubtless of foreign origin. However, discrepancies are explained anyway by metal in transit, process of refining, and accumulated stocks.

The distribution of the domestic production of virgin lead is given as nearly as possible in the second table. The total for this table does not agree with that of the first table because (1) lead derived from scrap is excluded, and (2) the figures in this table are based to a large extent upon the reports of the producers of work lead, which obviously show the origin of the metal much better than the reports of the refiners can do. Differences between the reports of smelters and refiners are, of course, explained by metal in transit, treatment, etc.

PRODUCTION OF LEAD BY STATES.

State.	1907.	1908.
Arizona.....	2,200	1,867
California.....	8,503	4,490
Colorado.....	47,332	26,707
Idaho.....	111,697	98,394
Kansas.....	1,800	2,400
Missouri.....	123,613	125,216
Montana.....	2,005	2,369
Nevada.....	3,400	3,676
New Mexico.....	1,900	611
Oklahoma.....	400	1,000
Utah.....	54,738	43,995
Wisconsin.....	3,500	3,486
Other States.....	1,204	600
Undistributed Zinc smelters.....	1,320	2,026
Total.....	355,959	314,067

The striking features of the statistics for 1908 are the further gain of Missouri as the premier lead-producing State and the decline in the production of nearly all of the other important lead-producing States, especially Colorado. It is probable that a large part of the lead that we have entered as "undistributed" (because we could not be sure of its source) belongs really to Colorado. The item entered under the caption of "Zinc Smelters" represents lead obtained from their residues, the origin of which it is next to impossible to trace.

Gold Production of Russia

The receipts of gold, reported in terms of the fine metal, at the government and private laboratories in 1908, were 1,279,805 oz. troy, compared to 1,166,032 oz. troy in 1907. Increasing these figures by 10 per cent. in each case, in accordance with our usual custom, in order to allow for gold clandestinely exported, or otherwise escaping official record, we estimate that the gold production of Russia in 1908

was 1,407,770 oz., compared to 1,282,635 in 1907. The increase was not altogether expected in view of the unfavorable conditions from which gold mining in Russia has been suffering, these having been the subject of general complaint. The major part of the increase in 1908 was due to the Rodaibi district in the Irkutsk Government, and the Yakutsk district, which comprise the most productive region of the Empire at present, this contributing about one-third of the total output. The Lena Gold Mining Company alone produced 273,865 oz. of fine gold in 1908, this being the most productive single undertaking in Russia. Indeed it must be in the first rank of the gold producers of the world. The Waihi mine of New Zealand in 1908 produced \$4,495,847.

The Virginian Railway

An event of much importance to the West Virginia coalfields occurred this week in the formal opening for traffic of the Virginia Railway, which has been under construction for nearly three years past. This road begins at Deepwater on the Chesapeake & Ohio, extends southeasterly for some distance and then eastward, passing through Norfolk and reaching tidewater at Sewell's Point on Hampton Roads. It was planned and built as a coal road chiefly, other traffic being merely incidental, and great pains were taken in its location to secure favorable grades for the eastbound traffic which will constitute the bulk of its business. In its construction some expensive work was required to overcome the grades where it leaves the Kanawha valley and at some other points where it crosses the mountain ridges running northeast and southwest. For a considerable part of the distance traversed it parallels the Norfolk & Western railroad and it will be a competitor of that road to a certain extent for coal traffic, although it will not interfere at all with the through southwestern business, or indeed with the local trade of that line. The total length of the road from Sewell's Point to Deepwater is 436 miles and some short branches bring the total up to 450 miles of railroad. The total cost is said to have been about \$30,000,000, including the extensive tidewater terminals.

The road will not be altogether a competitor of existing lines but will have, even at the start, some new trade of its

own. It will interfere very little with the Chesapeake & Ohio and will leave to the Norfolk & Western practically all the trade of the Pocahontas and Tug River fields. It will open up a comparatively new district in West Virginia lying between the two older roads; in this district several large mines have already been developed or are being developed.

An unusual feature of this road is that it has been built and is owned practically by one man, H. H. Rogers of the Standard Oil Company. His purpose in building the road, it is understood, was his belief that it would be a profitable investment of capital and it is expected that he will retain its control in his own hands. At any rate no arrangements have been made to distribute its securities to the public. We can recall no other case of a railroad built in this way since Asa Packer built the original Lehigh Valley railroad—the nucleus of the present Lehigh Valley system—practically single-handed in the early fifties. That was a sufficiently large undertaking for one man in its day, but was far short of the achievement of Mr. Rogers in building the Virginian railway.

Copper Production of the World

The annual statistics of Henry R. Merton & Co., Ltd., of London, received this week, show that according to its reports the world's production of copper in 1908 was 748,625 long tons, compared to 713,865 in 1907. The figures for the principal countries are given in the following table:

	1907.	1908.
Australasia.....	41,250	39,500
Canada.....	25,615	28,570
Chile.....	26,685	38,315
Germany.....	20,400	20,200
Japan.....	48,935	43,000
Mexico.....	56,565	37,570
Peru.....	10,575	15,000
Russia.....	15,000	20,085
Spain and Portugal.....	49,675	52,585
United States.....	892,230	425,175

We have previously commented upon the statistics for the United States, Canada and Mexico. As to the statistics for the remainder of the world, the most noteworthy features for 1908 are the large increases in the production of Russia, Chile and Peru. The increase in Russia was due largely to the operations of some of the new British concerns, such as the Spassky Copper Company; the increase in Peru was due chiefly to the Cerro de Pasco company, which now appears to be getting its gait. The increase in the production of Chile is particularly interesting. Many years ago this country ranked among the most important copper pro-

ducers of the world, but for nearly 20 years its output has been practically at a standstill. American and British companies are now becoming more extensively interested in the resources of that country, and their work is evidently reflected in the statistics for 1908, which show the largest production of copper in Chile since 1890. The statistics of Merton & Co. omit the production of Cuba, which amounted to 2966 metric tons in 1908, against 1388 in 1907.

A High Grade Copper Mine

It has become so much a custom to talk about copper mines that yield 1 to 2 per cent. of the metal, or translating the percentage into pounds per ton to sound better, that it is rather startling to find a copper mine producing on a large scale ore that assays about 30 per cent. copper. That is what the Poderosa Mining Company obtains at Collahuasi, Chile. This mine is also of interest by virtue of its being under the management of Robert Hawxhurst, an engineer well known in the United States. His company produces about 2000 tons of ore per month that assays about 30 per cent. copper, besides some "low-grade" ore that goes 11 per cent. copper and some "waste" that goes 4 to 5 per cent. In the six months ending June 30, 1908, the production of high-grade ore was 13,795 tons. At the beginning of that year the ore reserves were estimated at 100,000 tons, which amount was fully maintained by the developments of the semester. The production of copper in Chile in 1908 having been about 38,000 tons, it will be seen that the output of the Poderosa mines forms a respectable percentage of the total. The vein from which this ore is mined appears to be from 10 to 40 in. in width.

NO STRIKE NOR lockout has taken place in the anthracite region, both sides agreeing that work shall continue under the existing agreement, at least until another conference can be held. That conference begins today (April 7), but will continue probably for two or three days. Reports, which seem well founded, are to the effect that the miners' committee will give way, insisting only upon some small points for form's sake. The position of the operators is too strong to make a contest at all hopeful just now.

North Dakota Coal Lands

The first indication of the new policy that is to govern the Land Office under President Taft and Secretary of the Interior Ballinger was afforded on March 29, when by recommendation of the secretary, President Taft revoked an executive order issued by President Roosevelt in 1906, under which 1,866,000 acres of land in North Dakota were withdrawn from entry. This land was withdrawn in consequence of a report that it contained lignite coal, and that a combination of interests were trying to get a monopoly of the supply. The restoration of these lands now permits entries to be made under the general land laws applicable to that area. A statement issued by Secretary Ballinger on this topic says that if the lands are agricultural in character they may be entered under the homestead laws; if valuable because of workable deposits of coal they may be entered under the coal-land laws. This action will relieve from suspension and pass to patent a large number of homestead entries which had been suspended for field examination because of the existing withdrawal. President Roosevelt was understood to have withdrawn this land from entry in pursuance of his conservation policy. The new President's policy, according to the statements of officials in touch with this branch of the Government's operations, is "development of natural resources." The land laws were amended at the last session of Congress so as to permit homestead entries to be made on land "chiefly valuable" for agriculture. The old law would not permit such entries, even if the mineral deposits were nearly worthless.

The Bureau of Mines Bill

Senator Dick, of Ohio, chairman of the Senate Committee on Mines and Mining, has reintroduced the Bureau of Mines bill with some minor changes and intends to press it during the present Congress, though—in view of the decision (April 1) to bar legislation other than the tariff and the census—he will not be able to act at the current session. In the form in which it has now been introduced by Senator Dick, the bill provides for the establishment of a Bureau of Mines in the Department of the Interior, which is to make such investigations as may develop greater safety and efficiency in mining, extracting and utilizing the mineral substances of the United States and the investigation of materials of construction, fuels, and other mineral materials belonging to or for the use of the Government of the United States with a view to their more efficient use. The bill follows the measure of last session in

authorizing the Secretary of the Interior to transfer to the new bureau from the Geological Survey, the work of supervising the investigations of structural materials, the analyzing and testing of coals, lignites and other fuels, the investigation of the causes of mine explosions, and the inquiries into plans for the protection of the lives of miners. This work is, however, limited to the Territories of the United States, thus doing away with the objection raised against the old bill that it would give a bureau of mines power to make regulations which might interfere with the regulations of the States in regard to the same or allied subjects.

The bill further contains the following provision: "That no examinations shall be made for private parties or corporations except with the approval of the Secretary of the Interior and under such regulations as he may prescribe where such examinations involve the question of public safety, prospecting on public lands, or a serious waste of mineral resources; and in all such cases the cost of the examinations shall be charged against parties for whom the examinations are made, and the money so received shall be paid into the Treasury of the United States."

The Rio Tinto Company in 1908

The Rio Tinto Company in 1908 extracted 604,275 tons of pyrites for shipment and 1,115,610 for local treatment, a total of 1,719,885 tons. The quantity of cupreous ore invoiced to consumers in 1908 was 589,815 tons against 607,944 tons in 1907, and 632,307 tons in 1906. Of the deliveries in 1908 Germany took 300,361 tons, the United Kingdom 118,156 tons, and the United States 171,298 tons. The deliveries of sulphur ore, which were 477,843 tons in 1906, and 619,814 tons in 1907, were 688,477 tons in 1908. The copper produced in 1908 by treatment at the mines amounted to 24,256 tons, and the fine copper in pyrites shipped was 9958 tons, a total of 34,214 tons. The following quantities were marketed: Refined and blister copper, 25,093 tons; copper in pyrites, 9821 tons; total, 34,914 tons. The profit on the sale of products in 1908 was £1,446,504.

Satisfactory progress has been made with the opencasting of the San Dionisio Lode. Two of the tunnels, through which the overburden will be removed, are now complete, and progress has been made with the third or lowest outlet. The extension of the South Lode Open-cast is proceeding well, and will effect a more economical extraction of the mineral in the near future. The output of mineral for 1908 was considerably reduced through the subsidence mentioned last year, but no further slips have occurred.

March Dividends

The accompanying table shows the total amount, and the amount per share, of the dividends paid during the month of March, 1909, by mining and industrial companies in the United States, and by some foreign mining companies:

U. S. MINING COMPANIES.	Location.	Amt. per Share.	Amt. Paid.
Am. Smelters, pt., A.	U. S.	1.50	255,000
Am. Smelters, pt., B.	U. S.	1.25	375,000
Bunker Hill & Sul.	Ida.	0.20	60,000
Calumet & Arizona.	Ariz.	1.00	20,000
Calumet & Hecla.	Mich.	5.00	500,000
Colorado.	Utah	0.08	80,000
Doe Run Lead.	Mo.	1.50	94,888
Fed. M. & S. Co., pt.	Ida.	1.75	210,000
Homestake.	S. D.	0.50	109,200
MacNamara.	New	0.01	7,300
North Butte.	Mont.	1.00	400,000
North Star.	Cal.	0.30	75,000
Old Dominion, M.	Ariz.	0.50	146,622
Old Dom. M. & S.	Ariz.	1.00	162,000
Phelps, Dodge & Co.	Mich.	0.024	1,123,365
Quincy.	Ariz.	1.00	150,000
Round Mt. M. Co.	Nev.	0.04	31,933
Utah Copper.	Utah	0.50	365,000
United Verde.	Ariz.	0.75	225,000

U. S. INDUSTRIALS.	Location.	Amt. per Share.	Amt. Paid.
American Coal.	Md.	\$1.25	62,500
Crucible Steel, pt.	Penn.	1.00	244,365
Gen'l Chem., con.	U. S.	1.00	74,103
Nat. Lead, pt.	U. S.	1.75	260,820
Sloss Sheffield.	Ala.	1.25	125,000
Standard Oil.	U. S.	15.00	14,550,000

U. S. Steel, pt.	U. S.	1.75	6,504,918

FOREIGN MINING COMPANIES.	Location.	Amt. per Share.	Amt. Paid.
Crown Reserve.	Ont.	\$0.15	\$262,000
Esperanza.	Mex.	0.37	168,350
Kerr Lake.	Ont.	0.20	120,000
Le Roi 2.	B. C.	0.48	57,600
Mines Co. of Am.	Mex.	0.02	40,000
Pergrina M. & M.	Mex.	3.50	550,000

International Smelting and Refining Company

The organization of this company has been perfected by the election of John D. Ryan, as president, Dennis Sheedy, as vice-president, and John W. Allen as secretary and treasurer. The board of directors consists of these, together with U. H. Broughton, Charles F. Brooker, Thomas F. Cole, Adolph Lewisohn, E. C. Converse, Thomas Morrison, C. A. Congdon, Wm. D. Thornton and Charles F. King.

The new company has taken over the Raritan copper refinery, from the United Metals Selling Company, as of Jan. 1, 1909. The new Tooele smelter is under construction. The company is also considering the purchase of the Tintic smeltery in Utah and the Torreon smelter in Mexico.

Views, Suggestions and Experiences of Readers

Comments on Questions Arising in Technical Practice and
Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Electrically Driven Mine Pumps

To the interesting article by Sydney F. Walker in the JOURNAL of Feb. 20, 1909, may be added the experience of pumping by electricity in Aspen, Colo., where electrically driven mining machinery originated.

In Aspen all sorts of pumps have been used for mine pumping, from the old Cornish pump to the uptodate, highly polished and attuned electric pump. Some of the electric pumps have necessarily been freaks, on account of local conditions, and perhaps also attributable to the evolution of that class of mine machinery.

Several years ago one of the freak installations was an ordinary three-throw plunger pump driven by continuous-current shunt motor and placed at the collar of a shaft in a tunnel. It was to pump water from the bottom of the shaft 80 ft. to an ejector which in turn ejected the water, with the additional mine water, up to the tunnel or level of pump. This pump and ejector did the unwatering in sinking the shaft and carrying on continuous stopping.

Another freak, also an ordinary three-throw 7-in. plunger pump was placed in the bottom of a 220-ft. shaft as a station pump and was driven by 1/2-in. wire-rope transmission from the 20-h.p., continuous-current, shunt motor placed at the collar of the shaft. This pump was once, during a flood, submerged under 65 ft. of water, and kept on running for two days until the mine was drained. During that time the 20-h.p. motor developed 37 h.p. intermittently and at one time continuously for eight hours without injury, the increase of power being due to obstruction of the water to the transmission gearing.

The last electrically driven pump installed is a 7x12-in., five-throw, horizontal plunger pump driven by a 90-h.p., variable-speed, continuous-current, shunt motor, working under a head of 500 ft. at a variable speed of 45 to 60 revolutions, delivering the water in the same variable ratio, 450 to 600 gal. per min., at a combined efficiency of 87 per cent. The variation of flow of water is due to the damming up and emptying of water courses and to spring thaws, and at times the water is very muddy.

This pump has been running continuously for 18 months, not losing the water once, except for 20 min. at a time for each plunger every three months when renewing packing, at which times the water is

stored in an excavated sump under the pump. The cost of running the pump averages \$500 per month for 500 gal. per min. against a 500-ft. lift.

This form of pump takes the water from a state of rest and delivers it to the discharge column in a continuous stream, thus only limiting the speed by the strength of pump chamber, making a possible flexibility as to capacity of several hundred per cent., and consequently rendering it an ideal mining pump.

CHARLES E. ANDERSON.

Aspen, Colo., March 15, 1909.

The Nature of High Explosives

In the JOURNAL of Feb. 6, 1909, I find under the heading "Colliery Notes" the following paragraph:

"A nitroglycerin explosive is less sensitive with a small-diameter cartridge, but an ammonium nitrate explosive is more sensitive with a small-diameter cartridge."

I wish to take exception to this paragraph, as the statement made does not conform to our understanding of the nature of high explosives. It is a well known fact that detonation "carries" better in larger cartridges of all explosives, whether they be nitroglycerin dynamite, ammonia dynamite, ammonium nitrate compounds, gelatin dynamite or blasting gelatin, than in smaller cartridges. This does not apply to the actual sensitiveness, except that in long charges, a stronger detonator is required in those of small diameter on account of the resistance offered by the charge of small diameter to the detonation wave. In a way this is similar to the friction of liquids flowing in a small pipe as compared with those flowing in pipes of large diameter. In regard to the statement concerning the ammonium nitrate explosives (through which the detonating wave does not carry so readily as through an ammonia dynamite), it has been definitely proved that these explosives cannot be used with success except when packed in cartridges of a diameter equal to or larger than 1 1/4 in. The only explosive of this class which has been successfully used in cartridges of as small a diameter as 1 1/4 in. is Monobel. This is the result of a great many careful and extended experiments made by the technical division of the Du Pont Company under all conditions of practical work.

Wilmington, Del., Feb. 15, 1909.

Developments in Gold Dredging in 1908

I note with interest the article on this subject, by John Power Hutchins, published in the JOURNAL of Jan. 23, 1909. I also note Mr. Hutchins' observations concerning wooden hulls and their defects and his mention of structural steel having been used in connection with the wooden hulls for the purpose of strengthening the same. I would call attention to a form of construction that I designed and incorporated in a dredge which has given excellent satisfaction during two years' use.

In this design all of the gantries were of structural steel work and were joined together by a structural steel truss. This construction formed a regular Howe truss running throughout the length of the dredge with the front and rear gantry at each end and the main gantry carrying the upper tumbler in the center, there being two of these trusses, one on each side of the well and joined throughout their length at various intervals.

* The principal idea was to avoid composite construction; in other words, to avoid securing any one of the three gantries directly to the woodwork of the hull as it has been found almost impossible to secure steel work to the wooden structure in a satisfactory manner, the steel always cutting more or less into the woodwork when any strain was put upon it and thus becoming loose.

These three gantries being embodied in this steel truss-work made the whole structure a complete unit and the bottom chord of the steel truss simply rested on a sill or stringer running the entire length of the dredge, to which each of the floor beams was secured. This form of construction kept all the digging strains within the steel truss girder and at the same time this girder reinforced the hull so that there was no tendency of the hull to become distorted.

After two years successful operation of this dredge, careful observations have shown the hull and all the superstructure to be in perfect condition.

Further on in the article Mr. Hutchins speaks of steel hulls being more rigid and durable than those of wood and states that they should be used in tropical climates, but inasmuch as he states that no gold dredges with steel hulls have yet been built in the United States, one would naturally infer that this work had not been

taken up by anyone, whereas in the *JOURNAL* of Jan 23, 1909, it may be noted that the advertisement of the New York Engineering Company, on page 143, illustrates an all-steel dredge in which is embodied the structural steel truss girder construction for all the superstructure and gentries as described above, only this is built on the deck of a steel hull instead of resting on the floor of a wooden one.

I believe the day is near at hand for steel hulls in this country and excepting in one or two States where suitable pine is to be cut close at hand, this steel hull will not prove any more expensive than the wooden hull, and in most instances it would be cheaper on account of less labor involved in assembling the dredge.

The steel hull is readily assembled, requiring only pneumatic riveting and bolting in order to complete same, and the installation of the machinery is much more readily accomplished with the steel hull and superstructure as most all of this work is laid out and executed in the shop under favorable conditions and the assembling of the machinery on the hull in the field only requires bolting or riveting in place.

Mr. Hutchins also calls attention to the need of a small dredge for the exploitation of areas not suitable for a larger dredge. This need for a small dredge having been appreciated by me some time ago, I set about to design and build this all-steel form of dredge, advertised in the *JOURNAL*, especially in the smaller size having two cubic-foot buckets.

This form of construction results in a large saving in freight and transportation and labor in erecting. At the same time it provides a modern and efficient dredge at a very low cost and one that is especially designed for the exploitation of small and limited areas.

A. C. LUDLUM.

New York City, Jan. 29, 1909.

Lake Superior Iron Ore

I note in the statistics of "Lake Superior Iron Ore," in the *JOURNAL* of March 20, 1909, that ores from Mayville, Wis., mines are included with those from the Illinois mine of the Baraboo range. While it is advisable perhaps to include in some way the Mayville and Iron Ridge ores from Dodge county in Lake Superior statistics, yet from a geological point of view at least they should be kept separate from the ores of the Baraboo range.

The Baraboo ore is pre-Cambrian like that of the Lake Superior ranges. The Mayville and vicinity mines are in the Clinton iron-ore beds, like the Birmingham, Ala., ores. The Mayville mines have been worked for 60 years since 1849, the total production probably being between 2,000,000 and 3,000,000 tons, largely used

in local furnaces. The Baraboo range has been worked since 1903.

SAMUEL WEIDMAN.

Madison, Wis., March 25, 1909.

Sharpening Drills Underground

SPECIAL CORRESPONDENCE

The topical discussions introduced into the proceedings of the South African Association of Engineers promise to be a successful feature of meetings in the future. The scheme—introduced at the last gathering—is simply to supplement the regular proceedings by the reading of brief notes on some pertinent question, for informal discussion by those present, as remarks and criticisms made cannot have received careful previous consideration, the discussion is not reported verbatim in the *JOURNAL* of the Association, and the summarized version is submitted to speakers for correction. Members are thus encouraged to speak freely, and the truth of matters may be arrived at more speedily, if clumsily, owing to the absence of elaborate preparation of remarks, from which inadvisable, though serviceable, opinions are often omitted. At the last meeting of the association, Baron Mannerheim opened a discussion by reading notes on the advantages of sharpening drills underground—not by any particular method, though he is associated with the exploitation of an electric furnace. While the meeting was unanimously in favor of sharpening underground in deep-level mines, there was a wide divergence of opinion as to the means. W. Thomas, manager of the Jumpers Deep, reported the successful employment of Mowbray oil furnaces. These he has installed at several points in the mine so as to be near the working faces and reduce transportation of drills, where the vitiated air—apparently unimportant—can rise to old stopes or places where it cannot cause any deleterious effects.

The electricians claim that the great merit of the electric furnace is the infallible means it provides for maintaining exactly the critical temperature required to obtain the best results, from different classes of drill steel. It has been frequently urged that adequate attention is not paid to this side of the question in Rand routine practice, and that if the proper heat can be obtained by a scientific system, such as regulation in an electric furnace, the faults due to variation in coal or in oil furnaces, and to carelessness or ignorance on the part of the smith will be prevented. Working underground without centralization, which would largely neutralize the savings attributable to the scheme—the need of supervision must be greater, when furnace conditions are similar to those on surface. Mr.

Thomas claims that he has used his oil furnaces underground on drill steel of all qualities and that, owing to the ease of gaging the temperature by experienced observation, there have been no complaints as to faulty tempering.

It is most probable that the whole question will be thrashed out thoroughly by some expert, able to devote his whole time to the subject, in due course, and if the informal topical discussion mentioned has influenced the movement, its practical utility will have been proved substantially. In the deep-level mines, upon which the number of shafts of over 2000 ft., vertical with independent inclines to serve the ground below, are yearly growing in number, there is not only the cost of hoisting to be considered, but also the time taken in loading and unloading the skips or cages with sharpened or blunt drills, numbering thousands per day. There is also to be considered the benefit of bringing the users of the drills—the machinemen or hand-labor supervisors—into closer contact with the sharpeners. But it is necessary to be sure that the standard of efficiency is maintained.

Metallic Chromium from Chromite

A German patent (No. 205,789) has been granted to E. Viel, of Rennes, France, for a process of extracting metallic chromium from ferro-chromes or from natural chromite. The process consists in treating the raw material, mixed with lime or clay and a calculated amount of carbon, at a high heat in an electric furnace. This forms double silicates of iron or alumina and calcium, together with such other metals as may be present, aside from the chromium. The heating must not be long continued, or the double silicates will be dissociated.

Supposing the raw material to be a ferro-chrome containing 60 to 68 per cent. chromium and 8 to 12 per cent. carbon, together with such impurities as manganese, magnesium and alumina. This is pulverized, mixed with sand and lime, or a silicate of lime, and heated for 5 min. at a temperature of at least 3500 deg. C. A double silicate of iron and calcium is formed and also one of calcium and manganese, etc., which float on the calcium carbide, which is also formed. The heavy chromium metal goes to the bottom of the furnace. The whole mass is then poured into a deep receptacle and allowed to cool, after which the several layers are broken apart.

If chromite is used for the raw material, only enough carbon is added to reduce a part of the chromic oxide, while the oxides of iron, manganese, etc., will not be reduced at all and thus enter into silicates with the lime and sand. The time and the temperature of the treatment are the same as with the ferro-chrome.

Tariff Legislation

SPECIAL CORRESPONDENCE

On April 3 the Committee on Ways and Means, after a long session, announced the amendments to the Payne bill on which they had been working for more than a week. While these amendments, as made public by the committee, numbered about 60, few of them were of general interest. The only ones affecting the metal and allied schedules appreciably were in charcoal-iron (paragraph 118), which was raised from \$6 per ton to \$10 per ton; in paragraph 88 where fluorspar, which had been 50c. per ton crude and \$1.75 manufactured, was made dutiable at a uniform rate of \$1.50 per ton; in paragraph 134 where wire over No. 16 gage was changed from 1 $\frac{1}{4}$ c. per pound to 1 $\frac{3}{4}$ c.; and in paragraph 89 where mica was made 10c. per pound plus 20 per cent. when manufactured; 5c. per pound and 20 per cent. when crude, instead of being taxable at 30 and 35 per cent. ad valorem, as in the original Payne bill. Copperas, which was on the free list, is made dutiable at 0.15c. per pound. Carbon electrodes were added to paragraph 93, and put at 10 per cent. ad valorem. In paragraph 182 the word "ferrophosphate" has been altered to "ferrophosphorus."

PATENT PROVISIONS

An important alteration in the bill was made by dropping out the section on providing for a retaliatory patent policy. The section was simply cut out without the insertion of any substitute. This result was arrived at in consequence, largely, of representations on the part of the State Department, which informed the committee that it had practically settled the terms of patent treaties with some of the more important European countries under which we should be relieved of the retaliatory working of the patent legislation of those countries particularly insofar as concerns the so-called "manufacturing clause." This and the urgent representations of some of the best known patent attorneys in the United States sufficed to bring about the elimination of the objectionable section. It also appeared that to adopt the section would violate important international agreements.

IRON AND STEEL

One of the tariff schedules that is receiving the closest attention from the Senate Finance committee is Schedule C, which deals with metals. The portions of this schedule which relate to iron and steel were taken up for formal investigation on March 27, at which time a large delegation of iron and steel manufacturers, headed by Judge F. H. Gary, of the Steel Corporation, and Willis L. King, of the Jones & Laughlin Steel

Company, appeared before the committee. In general discussion the rates fixed in the Payne tariff bill were covered, and it was made plain that the steelmakers did not consider the schedule there established to be at all feasible. The chief criticisms made upon it were based upon the apparent bad adjustment of the rates to one another and the fact that, in many cases, products which should have been highly taxed with reference to others were set at a lower rate, while in other cases products which should have been placed on a lower basis were maintained at a high point. It is understood that the criticism of the Payne tariff followed substantially the lines that were pursued by Representative Underwood, of Alabama, in his speech before the House of Representatives in which he condemned the methods followed by the Ways and Means Committee in constructing the iron and steel schedule. Particular reference was made to the Payne tariff on scrap iron, and it was suggested that this should be made identical with the duty on pig or at least approximately equal to it, in order to prevent the introduction of broken pig under the head of scrap. Severe criticism of the treatment accorded to steel billets and rails was also afforded. While it was understood that the steel and iron representatives had been given a "hearing" in the usual sense of that term, Senator Aldrich has since denied, in a speech before the Senate, that such was the case. Mr. Aldrich refers to the incident as merely a consultation or "conversation" between the Republican members of the committee and some experts who were called in for consideration of the schedules.

IRON ORE

The treatment of iron ore in the Senate now seems likely to be radically different from that accorded to this item in the House. Reduction of the duty existing in the Dingley bill by about 20 per cent., making it 32c. per ton (instead of 40c.), with a further reduction of another 20 per cent. on Cuban ores coming in under the reciprocity treaty and thus reducing the rate to 25c. per ton is probable. This disposition of the ore question has been demanded by representatives of the minor ore-producing districts who believe that the introduction of free iron ore will be injurious to the business of their particular localities. There has been a strong desire on the part of the House leaders to adhere to the Payne treatment of iron ore, as in this way some semblance of the "free raw materials" policy could be maintained. It is unlikely that the House will at the last hold out against the Senate should the latter body restore one-half or two-thirds of the original duties on iron ore. Only as a result of extreme pressure and in view of the desire to make some show of introducing a liberal tariff bill

while at the same time satisfying most of the manufacturing interests did the Ways and Means Committee remove the Dingley tariff on ore, and there are several members of the committee who would welcome a chance to replace a tariff on this item in the list. The leaders have also felt quite keenly criticisms based upon the differences between their method of dealing with iron and lead and zinc ores.

COAL

Discussion of the tariff bill has developed some sharp differences of view with respect to the duty on coal. The Payne tariff provides for reciprocity in coal with Canada on a free-trade basis, and during the past week this has called forth strong protests from Western mining interests, as well as from those of Virginia and West Virginia. It has been the claim of these sections of the country that the effect of the new provision, if carried out by a mutual agreement with Canada, would be to deprive the domestic producer of a market for about 6,000,000 tons of coal in New England and to turn this market over to the Canadian producer. That the removal of the tariff of 67c. per ton on Canadian coal would not make a difference in ordinary retail prices exceeding 10c. per ton has been asserted on the floor by Representative F. W. Mondell, of Wyoming, chairman of the House Committee on Public Lands, in a set speech. It has been demanded by the coal interests that the tariff be restored at the rate of at least 45c. per ton, while they have also asked that the more favorable tariff treatment accorded to slack coal and culm in the bill be continued. Under the Dingley act, these forms of coal were dutiable at 15 per cent., but the Payne bill places them on an equality with other grades of coal. Were the duty to be restored at a flat rate of 45c. with no reciprocity provision, the new treatment of slack and culm continued, the domestic producer would consider himself in a much better position. The demand for this tariff program as regards coal has been made by Senator Elkins, of West Virginia, in conference with Senator Aldrich, of the Senate Committee on Finance.

DUTY ON LEAD

In a speech before the House on April 3 Representative Howell, of Utah, attacked the duties on lead carried by the Payne bill and submitted a lengthy memorial from the Conference of Lead Ore Producers of Colorado, Utah, Idaho and Nevada, addressed to the Senate and House, in which they requested that the bill be improved by the addition of such a differential duty on pig lead and refined lead "as will preserve the industry." The Ore Producers Conference urges that the proposed reductions would open the market to Mexican lead, to the detriment of our own industry.

Questions and Answers

Inquiries for information are answered in this department as promptly as possible, but more or less delay is often unavoidable. Many inquiries involve a good deal of investigation and these can be answered only when the general interest in the subject is conceived to justify the expenditure of the time required. Correspondents should refrain from asking for advice that ought to be obtained by professional consultation with an engineer. We will not answer questions pertaining to the value of specific mining enterprises. Inquiries should be framed concisely.

CHEMICAL ENGINEER

Will the JOURNAL please give its definition of a "chemical engineer?"

W. M.

A chemical engineer is one who has a fundamental knowledge of chemistry, and is sufficiently familiar with the principles of mechanical engineering to enable him to deal with problems of construction, operation and maintenance in connection with manufacturing processes including chemical principles.

INFUSORIAL EARTH

What is infusorial earth worth? Who deals in this material?

T. H. W.

Infusorial earth, best American ground, is quoted at 134¢. per lb.; best German ground, 2½ to 2¾¢. per lb., f.o.b. New York. The following are dealers in infusorial earth: W. H. Whittaker, 245 Front street, New York; Hammill & Gillespie, 240 Front street, New York; T. Van Amringe, 241 Water street, New York.

MONAZITE SAND

What is the price of monazite sand? Is any of this material imported?

S. M. O.

The United States imports practically no monazite or other thorium-bearing minerals. About 25 tons of thorium nitrate are imported yearly. The average price for 1907 was 12¢. per lb. for 90 per cent. monazite sand. The present quotations are 8¢. per lb. and upward, according to quality. Prices are published in the JOURNAL, in the chemical table which appears in the first issue of each month. The quotations given are the prices asked of the consumer by the dealer.

MONZONITE

What is monzonite? Although I find this rock referred to frequently in geological literature and know that it is a variety of what miners commonly call porphyry, I have been unable to obtain a precise definition.

P. T. A.

Monzonites are rocks occupying an intermediate position between the syenites and the diorites, i.e., rocks in which plagioclase plays a greater rôle than in the syenites but not so great as in the diorites. Lindgren has proposed that rocks having alkali feldspar to the extent of more than two-thirds of the total feldspar be classed with the syenites and with less than one-

third with the diorites, classifying the intermediate rocks as monzonites. This proposal has found adoption.

THE HYDRAULIC MINING CARTRIDGE

In the JOURNAL of Dec. 19, 1908, I notice on page 1211, under the head of "Colliery Notes," a paragraph concerning the hydraulic mining cartridge, which is being used successfully in England, Scotland and Wales. I will be much obliged if you will give me the name of the manufacturer of this cartridge, or refer me to some party who can do so.

E. L. C.

The mining cartridge concerning which you inquire is manufactured by the Hydraulic Mining Cartridge Company, 21 Mawdsley street, Bolton, England. A full description of this cartridge was published in *The Engineering and Mining Journal*, July 14, 1906. The cartridge has been successfully introduced in Canadian coal mines, but has not been introduced to any extent in the United States.

EFFECT OF ATMOSPHERIC PRESSURE ON THE FRENIER SPIRAL PUMP

What effect, bad or otherwise, does atmospheric pressure have on a spiral pump (Frenier's patent), and why should atmospheric pressure affect this pump? There is no vacuum formed.

T. N. W.

At each revolution of the wheel of the Frenier pump, more than half of the outside spiral coil is filled with air. This air becomes more or less intimately mixed with the sand and water which are forced up into the discharge pipe, and is compressed therein. At a high altitude, the volume of air taken in is the same as at a lower altitude, but it suffers a greater compression, and the air spaces in the discharge pipe being thus reduced, a heavier column must necessarily be lifted. The lifting power of this pump has been shown to be less by 4 in. for every increase of 1000 ft. above sea level.

PROPER SIZE OF HEADFRAME

I wish to erect a headframe to hoist a load of 6 tons. What is the proper height, and what dimensions should I use for front legs and backstays?

T. W.

For such information, a competent engineer should be consulted. Many factors, such as speed of hoisting, character of materials, position of backstay, etc., enter into such a consideration which, in themselves, determine the amount of the stresses. However, for an approximation the formula given below will give figures which will be amply safe even though not as economical as if the size of members was determined by a graphical or analytical study of the stresses involved:

$$S = \sqrt{\frac{8WH^2}{8}}$$

in which

S = Side of square section of front legs in inches;

W = Working load, on hoisting cable, in tons;

H = Height of frame, from ground to axis of sheaves, in feet;

Backstays = 5/9 section of front legs, of rectangular section in proportion of 3 to 4.

COAL BRIQUETTING IN THE UNITED STATES

What is the present status of coal briquetting in the United States? I am particularly interested to learn what success has been achieved by those who have attempted to briquet Western lignite coals.

E. S. M.

This industry at the present time may be considered as in its infancy. At various times elaborate plans have been completed for the erection of modern briquetting plants, only to be later held up by the parties interested because of the great uncertainty that surrounds the successful outcome of the venture. There are waterfalls in our country that are capable of developing thousands of horsepower annually, but are so located near large coal mines where fuel is cheap, that the work of harnessing these great natural agents would at present prove unprofitable. A waterfall at Goldfield, Nev., where coal sells for \$15 a ton would prove a bonanza, while the same source of power could not be profitably utilized at Pittsburg, where coal can be purchased for \$1.20 a ton. The same line of reasoning is applicable to the briquet industry. Experiments are now being made in the anthracite field, where the fine coal, that is not of great commercial value, is being made into briquets. It is too early to say whether the promoters of the industry in Pennsylvania will meet with success. The briquet industry has reached its greatest state of perfection in Germany, where a large percentage of the brown-coal production is made into briquets. The principal reason for the success of the industry on the continent is due to the fact that the brown coal will not stand transportation in its raw state, and can only reach the market after it has been made transportable by briquetting. There is no question but that the briquet industry in the United States stands the greatest chance of being successfully carried on in our Western States, where good fuel is scarce and where low grades of coal or lignite that cannot be satisfactorily transported are plentiful. The question of securing a suitable binder at a reasonable cost is also a consideration of much importance. One of our greatest transcontinental railroads has attempted to engage in the briquet industry in our Northwestern country, and the success of this venture will be watched with interest. Further information can be obtained by writing to the Renfrow Briquet Machine Company, St. Louis, Missouri.

Personals

Mining and metallurgical engineers are invited to keep *THE ENGINEERING AND MINING JOURNAL* informed of their movements and appointments.

S. W. Mudd, of Los Angeles, Cal., is visiting in New York.

C. N. Nelson is engaged in a prolonged examination of a mining property near Tucson, Arizona.

R. Britton Gottsberger has resigned his position as general manager of the Tennessee Copper Company.

Selwyn G. Blaylock, superintendent of the St. Eugene mine, East Kootenay, B. C., is back from a trip to the province of Quebec.

W. H. Aldridge, managing director of the Consolidated Mining and Smelting Company, of Canada, Ltd., was in Montreal recently.

Bruce R. Warden has returned from England to Nicola, B. C., and resumed his duties as engineer to the Nicola Valley Coal and Coke Company.

C. H. Benedict, chemist of the Calumet & Hecla stamp mills, is in the East, where he will deliver a series of lectures on the Lake Superior copper district.

R. E. Harris, president of the Nova Scotia Steel and Coal Company, has sailed for Europe in connection with the financial reorganization of the company.

H. S. Kerr, who has charge of the railroad and transportation interests of the Cerro de Pasco Mining Company in Peru, is visiting the United States on a leave of absence.

Gilbert S. Jones, district superintendent of the Temple Coal and Iron Company, at Pittston, Penn., has been suspended in consequence of the recent accident at the Mount Lookout colliery.

W. C. Seddon, of Baltimore, recently chosen chairman of the board of the Alabama Consolidated Coal and Iron Company, has been visiting the company's property in Birmingham, Ala., and vicinity.

G. A. McCarthy has resigned his position as chief engineer of the Temiskaming & Northern Ontario Railway to become superintendent of construction of a new power company, which will furnish electric power to the Cobalt mines.

Dr. B. Katsura, professor in the Technical College of the Imperial University at Tokyo, Japan, has been a visitor in New York. He will spend about five months in visiting mines and works in the United States, returning home by way of Vancouver.

C. W. Purington passed through New York last week on his way from London to Siberia. He will sail from San Francisco on May 13. He goes to undertake the management of the Kolchou placer property, near the mouth of the Amur river, for the Orsk Goldfields, Limited.

W. B. Devereux, Sr., and W. G. Devereux, of the firm of W. B. Devereux & Sons, New York, have been at Rhyolite, Nev., inspecting the Pioneer lease, in which they are interested. They are now on the way to Melones, Cal., to make an examination of the Melones mine.

W. J. Olcott, of Duluth, Minn., has been elected president of the Oliver Iron Mining Company, in place of Thomas F. Cole, resigned. This promotion was generally expected. Pentecost E. Mitchell succeeds Mr. Olcott as vice-president of the company. J. H. McLean, recently assistant to Mr. Mitchell, succeeds him as general manager.

Obituary

William Frank Hall died at his residence, Brooklyn, N. Y., March 4. He was well known and highly esteemed. For some time he had been connected with the Lehigh Car, Wheel and Axle Works, of Catasauqua, Penn., as New York representative.

Neil Black, well known in the Yale-Cariboo district of British Columbia as one of the pioneers of the famous gold rush to the Fraser river 50 years ago, was recently found dead near Spuzzum, in the cañon of the Fraser, where he had for years lived a lonely life in a small cabin. The very difficult work he accomplished many years ago as foreman of construction of the wagon road the government built through the Fraser cañon and thence to Cariboo was long a cause of much wonder to engineers and others.

Jacob H. Neff, one of the best known mining men of California, died in San Francisco, March 26. He was the first president of the California Miners' Association, an office he filled for six consecutive years. He was one of the organizers of that association, having presided at the meeting in Auburn, Placer county, where it was first proposed to make an attempt to rehabilitate hydraulic mining in California, and to form an association of miners for that purpose. Mr. Neff was a pioneer of the State and had mined in many portions of it, mainly in Placer county. He was one of the owners of the Morning Star drift mine on the Iowa Hill Divide, which paid dividends for many years, and was interested in other mining properties also. Mr. Neff was widely known among the miners of the whole State, and was highly respected by them all.

Jasper R. Rand, vice-president and director of the Ingersoll-Rand Company, died of pneumonia in Salt Lake City, March 30. Mr. Rand was the son of Jasper Raymond Rand, one of the founders of the Rand Drill Company, and was born in Montclair, N. J., in 1874. He was graduated from Cornell University in 1898 with the degree of mechanical engineer,

and served in Porto Rico in the Spanish-American war as a member of the New York Volunteer Engineers. During 1899-1900 he was president of the Imperial Engine Company, at Painted Post, New York, leaving that position to take the presidency of the Rand Drill Company, which he held until 1905. In that year he was elected vice-president and director of the Ingersoll-Rand Company, which was his chief interest until the last. Mr. Rand was a member of the Spanish War Veterans, of the American Institute of Mining Engineers, of the American Society of Mechanical Engineers, of the Engineers' Club, of the Cornell Club, and of the Alpha Delta Phi Club, of New York. He is survived by one sister, Mrs. Henry Lang.

Capt. William Moore, one of the oldest sea captains on the north Pacific, died in Victoria, B. C., March 28. He was known as the founder of Skagway, the Alaskan port through which passes practically the whole trade of the Canadian Yukon and adjacent parts of Alaska. In the early nineties Mr. Moore, who had prospected the territory now known as the Yukon, repeatedly urged the Dominion government to build roads and trails, so that prospectors might be able to get about the country, and he was tireless in predicting discoveries of valuable gold-fields. In full confidence that such would occur he occupied the site of what is now Skagway, and on the discovery of gold in the Yukon in large quantities, was instrumental in having the first large wharf built. All through the period of the big stampede into the Klondike he was a leading and most active resident of the "Gateway" town. Four years ago, his health having failed, he disposed of practically all his business interests, and removed to Victoria, where he remained until his death. He frequently expressed his belief that in remote sections of the northern country, of which he had knowledge, much gold would yet be found.

Societies and Technical Schools

University of Colorado—The members of the upper classes of the College of Engineering have been visiting mines, plants and works at Pueblo, Portland, Shoshone, Glenwood Springs, Leadville and Colorado Springs, on the annual inspection trip of the College.

Nova Scotia Mining Society—The officers elected at the recent annual meeting are: President, T. J. Brown; first vice-president, Prof. F. H. Sexton; second vice-president, G. J. Partington; secretary, A. A. Hayward; treasurer, H. M. Wylde; council, R. Drummond, B. F. Pearson, G. W. Stuart, C. E. Starr, J. R. Cowan, A. Dick, R. H. Brown, Thos. Cantley, A. L. McCallum.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at San Francisco, Butte, Salt Lake City, Denver, Mexico City and Paris

REVIEWS OF IMPORTANT EVENTS

San Francisco

April 2—The principal topic of discussion among the mining men continues to be the probable effects of the new eight-hour law for men working in deep mines and around reduction works, quartz mills, etc. Some of the mineowners think it will affect mining more than the milling, and others think the other way. In most mills the men work either 10 or 12 hours, and complying with the law of eight hours materially increases costs. One of the largest gold mines of the State in point of production is worked on the 10-hour system and the owners think the new law will increase costs of mining and milling ore from 25 to 30 per cent. Another of the large mines will quit mining its low-grade ore, hang up most of its stamps, and mine only the better grade ore and run 10 stamps to crush it. Numbers of small mines, milling their own ore, will perforce close down entirely, being unable to continue when they have to have three shifts instead of two in both mine and mill. This law applies to the quicksilver and other "underground" mines of the State as well as to gold mines. At those properties, while some skilled miners are employed, considerable unskilled labor is used in mines and about the furnaces. The principal quicksilver mine of the State is working ore containing 0.15 per cent. quicksilver and increase of expense will work a hardship. The quicksilver industry of California is in a bad way in any case, as the demand for the metal is less than the production and this additional expense will undoubtedly close down the smaller properties.

Over in Nevada where a similar law has lately gone into effect the big productive properties can stand the change, but those companies in the development stage will find it a hardship. The gypsum men are already complaining in Nevada and declare that they must close their plants on the enforcement of the law. These laws provide for the regulation of miners in the gypsum mines and plants and require that only eight hours' work must be done.

The entire equipment of the electric-power plant of the Bonanza King Mining Company, on the East Fork of the Trinity river, Trinity county, was destroyed by fire this week. The plant was only two years old and was a very fine one, costing some \$70,000. It was in fact much too big for the mine and mill. These will now have to close down. Several hundred thousand dollars were spent on this mine

and a 40-stamp mill put up. James Treadwell, the principal owner, was financially ruined in the failure of the California Safe Deposit Company, and 20 stamps of the mill were sold. The mine has lately been worked on a small scale, though it had one of the finest equipments of any gold mine in the State.

The Trinity River Mining Company has finished its tunnel through the point of land near Lewiston, Trinity county, and will turn the river through it when the water lowers. By diverting the stream about two miles of river bed at the horse-shoe bend will be laid bare for mining. The tunnel will carry all the water of the river at the ordinary summer stage.

The Shasta Power Company and the Northern Light and Power Company have consolidated under the name of the Sacramento Valley Power Company. The Shasta Power Company has its plant on Snow creek, 28 miles east of Redding, Shasta county, and the Northern Light and Power Company has its plant on Cow creek in the same county. The merger means a branching out and extension of the power lines.

Salt Lake City

April 2—Sixty per cent. of the stock of the Pioneer Ore Sampling Company at Sandy has been sold to Ernest R. Woolley and associates. The price involved was not made public, but it is announced that no change will be made in the business management of the company, Frank Higginbotham remaining in charge of the business and L. A. Copeland continuing as superintendent at the works. The mill is situated 12 miles south of Salt Lake City between the tracks of the Rio Grande and the Salt Lake, Los Angeles & San Pedro railroads. The plant enjoys common-point rates from all directions and its location greatly favors the shippers from the Alta and American Fork districts with an even break on the ores from Big Cottonwood cañon. Mr. Woolley's "associates" are not announced.

The Boston Consolidated has announced a new issue of stock. It is understood that the receipts from the new stock will be applied to pay the floating debt and to provide for the cost of new work at the mines. It is stated that the management expects to run the mill at full capacity of 3000 tons per day after sufficient stripping has been done to provide the mill with ore of which at least one-half is mined by the steam-shovel method.

In connection with the consolidation of the Tetro and Plutus companies, stockholders of the Tetro who do not desire to receive in exchange shares of the Plutus Mining Company may accept a dividend of eight cents per share for all stock turned in. The property of the Tetro company was sold for \$24,000, which amounts to approximately eight cents per share.

The Utah Fuel Company pleaded guilty in the United States Court to the charge of criminal conspiracy to unlawfully acquire 1440 acres of coal land in this State. For this act it has paid a fine of \$8000 and an additional \$192,000 for the coal extracted, and has relinquished the land which was acquired through "dummy" entry men as agricultural land. The agents of the Utah Fuel Company also forfeited \$14,440 which had been paid for the land.

The Utah Copper Company has placed an order for two new steam shovels and four locomotives for the mine at Bingham. The new additions will give the company a total of 10 steam shovels and 21 locomotives at the porphyry mine. This additional equipment is regarded as substantial evidence of the company's faith in its steam-shovel operations and would indicate an increased tonnage to go to the concentrating mill at Garfield.

Butte

April 12—At the Belmont mine of the Amalgamated the shaft is completed to the 1000 level, and the engine, which was formerly used at the Corra mine, of the Butte Coalition company, has been set in place and is practically ready for operation. This engine is good for at least 3500 ft. The Anaconda shaft is still out of use and will probably be so for some time to come. As soon as the Belmont is connected up with the lower levels of the Anaconda it is probable that the greater portion of the ore will be hoisted through the Belmont shaft; by this means a lift of 400 ft. will be saved, as the collar of the Belmont is about 400 ft. lower than that of the Anaconda.

At the Parrot the vein has been cut on the 2000 level and the showings are said to be satisfactory. Development work is also being carried on at the 1900 level. The Little Mina shaft of the same company has reached a depth of over 1200 ft. and a station is being cut on that level. When the station is completed a crosscut will be run to the vein, which is supposed to be about 500 ft. away.

Denver

April 2. As in the base metals of the ores of Leadville, the San Juan region, Aspen, Georgetown and Red Cliff lead largely predominates, naturally the mining fraternity of this State, having a wholesome fear of the lead of Mexico and British Columbia, is wholly and strongly in favor of a protective tariff and is bringing all the guns it can muster to bear on Washington. And as zinc is largely associated with the ores of the aforementioned districts, the same desire for protection of that metal abides with us. It is stated that at the conference in Salt Lake City of lead-ore producers of Utah, Idaho, Colorado and Nevada, which has just closed there, more than 60 per cent. of these interests in the United States were represented, and the work of compiling statistics and information on the subject, which are to be forwarded to Western senators and representatives, is in the hands of the committees of the new Western Lead Ore Producers Association, which was formed as a result of the conference. So our wishes are likely to be well and strongly put, and will doubtless get an impartial judicial hearing.

In the Cripple Creek district, the output for March is given at 59,704 tons, of a gross value of \$1,340,790. The deep drainage tunnel is now beginning to enter that part of the area where mineralized veins may be expected to be encountered; and at 5400 ft. from the portal a fluorine-stained vein is reported as having been intersected. The present breast of the tunnel is now in the phonolite hill known as Grouse mountain, a short distance south of Beacon hill. The Delmonico, on Bull hill, formerly owned by W. S. Stratton, is the scene of a strike reported as four feet of pay ore.

The Ferris-Haggerty and Doane Rambler copper mines, near Grand Encampment, Wyo., together with the smelter, 16-mile tramway, etc., formerly owned by the Penn-Wyoming Mining Company, have passed into the hands of the United Smelters, Railway and Copper Company, capitalized at \$10,000,000. The new company is said to have \$250,000 in its treasury, and will proceed to develop ore reserves in the mines. This is badly needed as adequate development was not maintained ahead of extraction.

At Georgetown, the 250-ton mill for the treatment of the Pelican dump and customs ores will be started in a few days. At Red Cliff a number of new concentration plants are under construction and will be completed this summer. The mines are busy getting out ore for treatment in these new mills.

In the San Juan region, the Revenue-Virginius of Ouray which has been closed on account of shortage of water is starting up again. The Virginius vein was first tapped by the Revenue tunnel on the Uncompahgre side of the divide, and followed through the main range to the San

Miguel side, where the company is working on the Montana, its extension, which has its outcrop in Smuggler Basin. The chief values are in silver and gold.

Great interest was manifested in the Denver visit of Chief Forester Pinchot, who seemed anxious to meet the miners and hear the many complaints made against his policy, and if possible to remedy the wrongs complained of. That the practice of taking up mining claims simply for the purpose of acquiring the timber on them has been extensively carried on is well known, and this the forester very properly means to put a stop to; but that injustice has been done to a great many genuine prospectors by the subordinates of the Forest Service is also certain.

The prospector who has located his claim in good faith and done his best to develop it according to his means, should not be subject to the dictum of a \$65-a-month ranger, who has no knowledge of mines or minerals, as to whether he has a valid mineral claim. The present condition of affairs, however, is unquestionably this: that owing to the misplaced zeal, sometimes arrogance and generally ignorance of the subordinates in the Forest Service, hardly any prospecting for metalliferous mines is being done on Colorado mountains which now are nearly all in the national forests. Mr. Pinchot has informed me that in future all disputes with miners and prospectors as to the validity of a claim within the forest reserves will be passed on by a thoroughly qualified mining expert.

Indianapolis

April 5.—By virtue of a decree of the Federal Court, Master-in-Chancery Daniels will offer for sale at Bloomfield on May 1, the real estate, personal and mixed property, rights and franchises of the Southern Indiana Coal Company, including the Lattis Creek mine, the Greene County Coal Company mine, Tower Hill mine, Midland mine, Mammoth Vein mine, Linton Semi-Block mine and the Keystone mine; also all the coal and other minerals underlying the surface of a large acreage of lands in Greene county. The sale of this property is regarded as the largest transaction in coal lands and coal-mining property that has taken place in Indiana for some time. The indications are that the sale will attract a large number of investors.

Toronto

April 3. The Ontario government has appropriated \$50,000 for the construction of a wagon road from Charlton to Gowanda. A grant of 2,000,000 acres of land will also be made to the Canadian Northern railway as an inducement to construct a line from Sellwood to Port Arthur which, in addition to opening up a fine agricultural region, will tap the Gowanda and other mineral districts. This

offer is conditional on the commencement of the road within one year and its completion by the end of 1913.

Mexico

March 26.—The movement for the organization of an institute of mining engineers and metallurgists for Mexico is taking definite shape. An organization committee, mostly from Mexico City and vicinity, has held several meetings to formulate the constitution and by-laws and to arrange for a general meeting to perfect the organization, to be held in June or July in Mexico City. The new society will be known as the "Instituto Mexicano de Minas y Metallurgia."

The mining interests of Mexico are still concerned about the effect of the merger of the railroads and the resulting government ownership through a control of a majority of the stock in the consolidated company. The proposed raise of ore rates has been held in abeyance by the Federal commission, because of the depressed condition of mining in the country. It is uncertain when the advance may go into effect, and this is holding back much new work. The government rate commission also has under consideration a raise in freight rates on coal from Gulf ports to protect the growing coal-mining interests of Coahuila and Nuevo Leon from the imported American coal. The smelters and mines are affected adversely by these propositions and have succeeded in securing more or less effective modifications of the proposals backed by the coal-mining interests.

A plant to demonstrate the application of the Delprat & Potter zinc-flotation process will be erected in Mexico City by an English company of which H. Lawrence Read, of Australia, is the managing director. The company controls other processes, and proposes to engage extensively in the testing of low-grade and complex ores in the Mexican field.

The zinc interests of Mexico are much concerned over the proposed zinc-tariff legislation in the United States. The 20 per cent. ad valorem duty which has been imposed during nearly two years has greatly curtailed the operations in Mexico in zinc mining. With the duty removed, the zinc miners are confronted with the arbitrary imposition of a lead-tariff tax on ore containing over 0.3 per cent. lead, with the prospect of the enactment of a new tariff on zinc ore. Some zinc ore is being shipped from Mexico to Europe and it is likely more will go to that market in the future especially if a high tariff results from the campaign in the States.

The smelters of Mexico are now, for the first time, confronted with a scarcity of silicious ores resulting from the general introduction of cyanide treatment, and the curtailing of operations in the silicious silver-ore producing camps due to the low price of silver.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Alabama

Southern Steel Company—Notwithstanding the filing of several petitions in the Federal court at Birmingham, Ala., asking for a review of the order of sale in bankruptcy of the properties of this company, there appears to be no doubt that the sale will come off on the date originally fixed, April 12. The reorganized company is prepared to make the purchase. Much litigation is still promised in this case.

CALHOUN COUNTY

Cumberland Mining Company—This company, with headquarters at Knoxville, Tenn., has bought property at Tredegar, where it will mine quartz and put up a grinding plant to turn out pure silica.

Alaska

JUNEAU

Alaska Mexican—February: 120-stamp mill crushed 18,510 tons; estimated value of bullion, \$42,308. Saved 343 tons of sulphurets; estimated value, \$29,169. Working expenses, \$29,177.

Alaska United—February: Ready Bullion claim 120-stamp mill and the 700-ft. claim 100-stamp mill crushed 28,165 tons; estimated value of bullion, \$38,893. Saved 476 tons of sulphurets; estimated value, \$26,376. Working expenses, \$52,024. The 700-ft. claim mill lost several days during the month owing to lack of water, in consequence of the severe weather.

NOME

Reports from the Innoko and Candle districts give promise of satisfactory production and many new strikes have been made. Fifty new outfits are about to begin work at Center creek, in the immediate vicinity of Nome. Twenty outfits are at work on the Submarine beach. The Pioneer Mining Company, on Little creek, is working with full force. A large number of outfits are at work at Black creek on low-grade gravel.

Arizona

COCHISE COUNTY

Bowie District—An aerial tramway is being installed by Mr. Howle to transport ore from his mine to the station. The main working tunnel is now in about 300 feet. It is reported that Mr. Howle is arranging to ship 100 tons daily to the Calumet & Arizona smelter at Douglas. The ore is said to carry a fair amount of gold.

Mascot—Captain Tibbitts is in charge and is reported to be working in good copper ore.

Cowboy—Pence Brothers, owners of the Overland Gold and Copper Company, are doing some development work. The ores carry both gold and copper.

California

CALAVERAS COUNTY

Morgan—When the new air compressor, recently received at Irvine, is ready to run, quite a lot of development work will be done.

EL DORADO COUNTY

Sunshine Mining and Development Company—Final payment has been made on the claims bought of A. A. Macdonald, near Grizzly Flat. B. F. Hulings and Robert Martyr, of Sacramento, who are principally interested, will carry on active mining and install new machinery as soon as weather permits.

INYO COUNTY

The proposed purchase of the Needles smelter by the Tecopa Mining Company has fallen through.

Buckeye—The property in the Fish Spring hills consists of a quarry of low-grade ore. A double-compartment shaft is being sunk.

Harrisburg—This place has had its question of ownership cleared up, and men are grading for a new mill. This is in Skidoo district.

Inyo-Coso—The mine at Junction, 20 miles south of Darwin, is being developed and the mill has been finished.

Lanc—Reynolds & Peterson, lessees, are shipping high-grade ore to the smelter at Keeler.

KERN COUNTY

Simmons—This property at Piute has been bonded to R. E. Galloway, J. A. Ross and G. E. Parker. Machinery has been purchased and work begun. The name has been changed to the Monte Carlo Mining Company.

MARIPOSA COUNTY

O. A. Harland and others, of San José, are building a new custom mill at Hornitos to handle ore from the mines of that district which have no mills. There are several dozen small mines in that locality without mills.

Sorrell—This mine, F. L. Wallingford, superintendent, has a new mill which is nearly completed.

Exchequer Mining and Power Company—At the annual meeting the price of electricity per horsepower was fixed at \$7 per month for the mines at Hornitos. J. J. LeTourneau, of Duluth, Minn., was re-elected president and Dr. E. S. O'Brien secretary and manager.

MODOC COUNTY

Hess—The quartz mill put up on this mine at Canby has been started. The gold is very fine, and there are doubts as to whether it can be saved by milling without a cyanide plant. This is the only quartz mill in the county.

Fort Bidwell Consolidated—George F. Atkins, secretary, states that a 6-in. streak of ore in the Mountain View claim is panning out very well; and in addition to this there are 6 ft. of ordinary milling ore in the Sugar Pine claim. A 10-stamp mill will shortly be installed.

MONO COUNTY

Lucky Boy—T. J. Hubbard, lessee, is shipping a carload of ore per day. About 70 men are at work. The whole property is being worked by leasers.

NEVADA COUNTY

Native Son—This property, owned by Wisconsin men and managed by J. Bishop, at Nevada city, is to be operated on a larger scale. A new tunnel is to be run.

Champion Mines—Thirty of the stamps are dropping on leasers' ore, and 20 more are working on ore from the Home claim. There are 54 tributaries at work, and about 20 more men are working for the company.

Pittsburg-Gold Flat Mines Company—The old drain tunnel has been tapped and is being repaired. The shaft is being repaired down to the drain tunnel. The old water-power hoist has been put in order and the foundations for the new compressor are nearly finished. Excavations are being made for the new electric plant. The Pittsburg will be worked on a large scale when the water is all out.

PLACER COUNTY

Orphcum—At the Ophir, adjoining the Gold Blossom, the electric hoisting and pumping plants have been installed, and a new stamp mill will shortly be purchased.

Lewis Hill—At this property, near New-castle, a line of operation has been laid out showing that a short extension of the workings northward will open into the pay gravel.

PLUMAS COUNTY

Seneca District—Mark Miller has struck a rich spot in his gravel mine near the old Cariboo diggings. The new quartz mill in Butte valley has had the effect of bringing a number of people into the section. Dunn Brothers have added five stamps to their five-stamp mill.

SIASSA COUNTY

Winthrop—About 70 tons of ore are being shipped daily to the Bully Hill smelter. The completion of the railroad has made it possible to make these shipments from Copper City.

Midas—The clean-up for February approximated \$30,000. P. J. Harney has been elected president of the company in place of Captain Roberts, deceased.

SIERRA COUNTY

Doreneville—The quartz blocked out at the Grey Eagle mine is of a satisfactory grade. Concentrators are being installed in the Papoose mill. It is expected that the York mine will soon be reopened.

Von Humboldt—Arrangements are being made to reopen this property in American Hill district. Austin & Spencer, sheepmen of the foothills country, are putting up the capital. The district is heavily timbered and well watered. There are both gravel and quartz claims.

SISKIYOU COUNTY

San Jose Ditch—This old ditch, starting about 11 miles above Scott Bar, is being cleaned out and repaired to bring water to Scott Bar mines.

TRINITY COUNTY

Yellow Jacket—J. F. Tourtelotte, one of the owners of this group in East Fork district, states that the company is driving the tunnel ahead on the pay shoot, and the 30-in. ledge is looking well. A new shaft is also about to be sunk on the ore.

TUOLUMNE COUNTY

Green Spring—J. P. Casaneve and C. E. Wilcox have purchased a half interest in this mine for \$15,000, and will pay 20 per cent. of the gross output to the original owners until the last payment is made.

Ellen Winton—E. H. Truett, the new owner, has commenced the work of development.

Jupiter—This mine, near Jacksonville, has been bonded to A. F. Cook, of Alameda, and development work is under way.

Colorado

HINSDALE COUNTY

Indiana & Colorado—W. T. Moneyhun,

manager, is planning to erect a concentrating mill on Henson creek, near Lake City.

LAKE COUNTY—LEADVILLE

Iron Silver—The properties of this company were closed for three days, out of respect to the memory of Waldemar Arens, who was general manager and financial agent of the company for 30 years. The mines have resumed operations and are producing about 400 tons daily of different grades of ore.

Little Evelyn—Active prospecting work is in progress in lower South Evans Gulch, through the White Cloud shaft. Several stringers of ore carrying good gold values have been encountered.

Sedalia—This property has been sold at sheriff sale to the Cribbage Mining Company for \$50,100. The latter company is closely allied with the Yak Tunnel interests.

Yak Tunnel—The bore is now passing the Fortune territory and entering into Big Evans Basin. It is being driven at the rate of 350 ft. per month.

SAN JUAN COUNTY

Gold King—Between 4000 and 5000 tons of concentrates which have been tied up by the blockade on the Gladstone road, were shipped out during the month of March.

Hercules—The mill on this property is shipping concentrates at a rate of over one car per day.

Tiger—Harry Hilderman and associates, who are holding a block of ground on this property, have made a shipment of \$40 ore.

SAN MIGUEL COUNTY

Crown Point—The old Suffolk mine and other properties at Ophir are to be operated by the newly organized Crown Point Mining and Milling Company. Geo. C. Franklin, general manager. The mill is being remodeled and other improvements are being made. John Lape, superintendent.

TELLER COUNTY

Acacia—The Burns lease is now shipping ore of smelting grade from two ore shoots on the 250-ft. level. In the South Burns mine shipping ore has also been found and royalties between March 1 and March 25 have amounted to \$1850. Smelting ore is being shipped from the Morning Star claim. A new shoot has been opened on the extension of the Pinnacle vein.

White City—Ore of low milling grade is being shipped from the surface workings of the Friday claims. A 3-ft vein of smelting ore has been found on the 200-ft level.

Lucky Corner—A shipment of five cars of high-grade ore has been made from this mine. The ore has heretofore been brought to the surface through the Ophre-

lia or Moffat tunnel, but a new ore house is now being constructed at the shaft.

Delmonico—A high-grade shoot, liberally sprinkled with sylvanite, has been encountered on the 700-ft. level of this property on Bull cliff.

Ophir—Work is in progress on the new high-grade orebodies recently exposed at the 700- and 1000-ft. levels on Raven hill.

Cripple Creek—New information, charging conspiracy and obtaining money under false pretences, has been filed in the District Court against the six men recently arrested on a charge of "salting" gold ore shipped to the Golden Cycle mill from claims leased by them.

Indiana

GREENE COUNTY

As a result of a conference of mine officials and a Mine Workers' committee from the Island Valley mine near Bloomfield, and officials of the State operators and mine workers' organizations, four of 10 miners suspended for loading "dirty" coal, will be reinstated, and six will be suspended indefinitely. The dirty-coal proposition is the most serious one in the mining fields at present. The wages contract leaves the matter somewhat indefinite as to just how much dirt a miner can load.

Trouble is brewing at the Summit mine over the slate and dirty-coal question. The district officers have ordered the miners to clean up the slate and dirty coal.

Vandalia mine No. 3 near Linton has been closed. This mine is one of the old-timers of this field. The land is about worked out.

A riot occurred among the American and the Hungarian miners at the Bogle mine, three miners being killed and five injured. As a result the foreigners were driven out of the district and the mine superintendents have advertised for additional American miners.

VERMILION COUNTY

Deputy mine inspectors have filed 14 affidavits for violations of the State mining laws at Clinton. Ten of these are against miners for drilling beyond cutting and one against a miner for opening a powder keg with a pick. Three mine bosses are under charges of not conducting the ventilation of the mines properly. They had been working more than 50 persons on one air current, which is contrary to law. The mine inspectors say that there are many violations among the miners and that they have to be very vigilant to keep track of all of them. Men take chances in violating the law in order to make a part of their work easier.

The Miami Coal Mining Company, with offices in Clinton and which owns much good coal land in Vermilion county will soon begin the sinking of a shaft for a new mine near Clinton. H. V. Sherburn, is president.

Maryland

Consolidation Coal Company—The stockholders at the recent annual meeting in Baltimore, voted to increase the capital from \$10,250,000 to \$20,000,000. Of the new stock \$6,150,000 will be issued to present stockholders as a dividend of 60 per cent., representing additions to property made out of earnings. The remaining \$3,000,000 will be held in reserve, to provide for future additions.

Michigan

COPPER

Keweenaw—Stamping at the Phoenix mill was discontinued after running an extensive test on the Medora shaft rock, the results being unsatisfactory. At the 11th level drift a formation known as the west fissure vein, was encountered, but upon farther opening at the 13th level it was found practically barren. Further development work will be carried on from this point, and during the summer, openings will be made on the Osceola and Kearsarge lodes. The office of the company was recently moved from New York to Hancock, with C. A. Wright, Jr., secretary and treasurer in charge.

Hancock—The crosscut which connects No. 1 and No. 2 shafts at the 13th level is completed. This will be the main working passageway through which all the rock from the levels above will be hauled to No. 2 shaft. This shaft is below the 18th level, and at that point preparations are under way to drive another crosscut to the Hancock lode. This crosscut will handle the rock between the 13th and 18th levels.

Copper Range—The improved conditions in the Trimountain property continue. The best showing is at No. 4 shaft in the drifts below the 11th level. Shafts Nos. 2 and 3 are opening better ground at the 14th level. Diamond-drill operations are in progress on sections 7 and 8, which are held under option from the St. Mary's Mineral Land Company.

Quincy—The wooden shafthouse over the Pontiac has been completed. This shaft is down about 350 ft. in encouraging copper ground.

Franklin—The Pewabic lode has been reached at the 25th level by means of the crosscut and the formation is well charged with copper. Drifting continues on this lode at the 13th and 24th levels with undiminished richness.

Arcadian—At a meeting held at Houghton reorganization was perfected. The new company is to be known as the New Arcadian, organized under the laws of Michigan with a capital of 150,000 shares, par value, \$25, \$10 paid in. The old officers and directors were reelected. It was also decided to give the New Baltic Ex-

ploration Company an option on the quarter section of land in Section 16.

Victoria—Good copper-bearing ground continues to be exposed at the drift extending from the 22d level; this is the most important development at the property in a long time. The mine is operating on ore yielding about 13 lb. of copper to the ton. The hydraulic plant is being hindered in its operation by lack of sufficient water due to the continued cold weather.

Seneca—This company is drifting from the first level of its shaft at a distance of 200 ft. from surface. The formation is badly shattered with very little copper showing.

Ojibway—The crosscut from the 650-ft. level of No. 2 shaft has reached the lode. The shaft is down to the 800-ft. level. At No. 1 shaft sinking continues toward the 800-ft. level.

Ahmeek—The structural steel for this company's new stamp mill has been delivered and is being rapidly erected. Excavating is under way for the pumping station. Work at the two new shafts is being vigorously pushed. At the central crushing plant, which handles the rock from the two producing shafts, a large electric motor has been installed to drive the two 24x36-in. rock crushers.

Lake—The shaft is sinking below the third level. At the third level the crosscut is being driven westward to cut the main lode.

North Lake—Diamond-drill hole No. 3 is down over 700 ft.. The No. 4 hole is down about 225 ft. and entering the ledge. Nothing of any importance has been revealed.

Mass—A new copper-bearing lode was opened by means of a crosscut driven from the 27th level of "A" shaft. This lode is about 125 ft. from the Evergreen lode, which, together with the Knowlton, have been the main working formations of the company. The location of this lode was first revealed by a diamond-drill core.

Michigan—This company has opened an old adit and has found a very encouraging grade of stamp rock.

Tamarack—The report for the year 1908 shows a loss of \$153,217 incurred by operations. Rock stamped, 654,807 tons; mineral obtained, 19,134,429 lb., containing 66.93 per cent. refined copper, or 19.6 lb. of copper per ton of rock. The total cost of the refined copper was 15.24c. per lb. Mining, smelting and other expenses were \$1,870,191; construction, \$32,851; exploration work, \$49,537; assets, \$1,701,450; liabilities, \$1,314,114; balance of assets, \$477,366.

Nevada

ESMERALDA COUNTY—GOLDFIELD

February Premier Lease—Fifteen men

are employed. A crosscut is to be run east from the 220-ft. level.

Goldfield Consolidated—Development work on the new strike proves the extent of the orebody to be larger and richer than first reported. Eight cars of ore recently shipped to the Western Ore Purchasing Company yielded returns in excess of \$150,000.

ESMERALDA COUNTY—MINA

Marble Quarry—Davis Brothers, of Yerington, recently purchased the quarry, and will equip it with modern quarrying machinery. They also own 60 acres adjoining, thus making a property of about 125 acres. The marble is jet black traversed with green, gold- and copper-colored veins and takes an extremely high polish.

ESMERALDA COUNTY—HAWTHORNE

Lucky Boy—The Alamo lease paid its first dividend March 24, amounting to \$25,000, or 10c. per share. At present the mine is shipping an average of 1000 sacks of ore per day. Sixty men are now employed at the lease and 125 horses are engaged in hauling the ore to Hawthorne, six miles distant.

HUMBOLDT COUNTY—WINNEMUCCA

Rose Creek—Molybdenite has been found in several places by A. Zeidler on a group of claims about 10 miles west of Winnemucca. A shaft will be sunk and prospecting carried on.

HUMBOLDT COUNTY—SEVEN TROUGHS

London Syndicate—Work is being rushed on the mill as fast as possible. The tube mill was shipped from San Francisco March 20. The sampler is being put in place and the cyanide department is nearly completed.

English George—The clean-up of a 10-days' run in the Badger Hill mill resulted in 65 lb. of amalgam valued at nearly \$4000. The ore from the lease is now averaging between \$15 and \$20 per ton.

Reagan—The clean-up in the Mazuma Hills mill treating ore from this lease resulted in a recovery of over \$6000 for 100 tons of ore treated.

HUMBOLDT COUNTY—CHAFEY

Chafey Mines Company—This is a newly organized company, capitalized at \$1,000,000 in \$1 shares. The company will operate the Black Hole property and two additional groups of claims. Mr. Chafey is president of the company and H. C. Oastler, secretary.

LYON COUNTY—BUCKSKIN

Kennedy Consolidated—Work is to be resumed by Stebbins & Green who have a two-years' lease. Water has been encountered in the shaft, now 210 ft. deep, and a pump will be installed.

LYON COUNTY--YERINGTON

Nevada-Douglas—L. Humphrey, consulting engineer, in a report to this company, estimates 599,530 tons of 5.4 per cent. copper ore available. He also estimates 246,700 tons of probable ore averaging 3.60 per cent. copper.

LINCOLN COUNTY--PIOCHE

Moapa Forest—The president has signed a proclamation creating an addition of approximately 45,000 acres to the Moapa national forest reserve. This addition is at the northwest corner of the Charleston division.

Nevada-Utah—The body of silver-lead ore opened on the 700-ft. level of the Day mine is now said to show a width of 130 ft. and limits not yet reached. The same body of ore has been opened on the 600-ft. level and on the 800-ft. The ore is said to assay 10 to 15 per cent. lead and 20 to 40 oz. silver per ton.

Great Eastern—A large body of ore containing copper, nickel and platinum has been cut on the third level of this mine at Bunkerville.

Lead King—The owners of this mine have given a lease to some Goldfield operators, who expect immediately to inaugurate developments.

NYE COUNTY--BULLFROG

Montgomery Shoshone—It is estimated that the tonnage for March was in the neighborhood of 6000 tons. Eleven bars of bullion were shipped during the week.

Tramps Consolidated—A car containing 18 tons was shipped last week to Needles by three sets of leasers. The bulk of the shipment came from the Kuliachi-Vucovich lease on the fourth level.

NYE COUNTY--JOHNNIE

Johnnie Consolidated—As a result of 13 days' run at the mill a bar of bullion worth \$10,000 was shipped from the property last week. About 100 tons are treated daily, by the 15 Nisson stamps. The shaft is 750 ft. deep.

WHITE PINE COUNTY

Giroux—In the report for the year ending Jan. 31, 1909, the president states that milling was commenced in November, but the crushing machinery proved inadequate. Additional Chilean mills and rolls brought the work up to estimated capacity. The ratio in concentration was about 12½:1. The Alpha shaft was continued to the 1200-ft. level, the flow of water increasing with depth. A winze sunk on the orebody showed a width of 4 to 40 ft., the high-grade ore being maintained for a distance of 110 ft. Early in January a crosscut driven to connect with this winze penetrated a body of massive copper ore. About the end of 1908 a proposition was made to purchase the property for \$6,000,

000, which offer was declined. This was followed by the purchase of a large interest in the company's stock by Thomas F. Cole and associates. Energies will still be directed to the development of the ground opened by the Alpha shaft, which is confidently expected to show a large deposit of high-grade carbonate and sulphide ore. Further developments will be prosecuted in the porphyry ore to permit of milling on a larger scale. A large portion of the porphyry deposit can be mined by steam shovel. At present the treasury has \$1,000,000 available.

Cumberland-Ely—Production in March was 1,636,171 lb., compared to 1,233,492 in February, and 1,094,218 in January.

Nevada Consolidated—Production in March was 2,169,088 lb., compared to 1,035,000 in February, and 1,451,000 in January.

Montana

BUTTE DISTRICT

British Butte—The dredge at this property has been closed down due to the burning out of one of the motors. Operations will be resumed as soon as the necessary repairs can be made.

Butte Superior—It is stated that a zinc mill will be erected near the Black Rock shaft of this company. Large bodies of zinc ore have been opened up in recent development.

East Butte Extension—Operations have been resumed. The work is being done at a depth of 250 ft., the bottom level of the property.

Tuolumne—Work has been partially suspended while the new equipment is being put in place. The shaft has reached a depth of 1395 ft. It is expected that crosscutting for the vein on the 1400 level will be in progress before May 1.

JEFFERSON COUNTY

Corbin District—Four tunnels are being driven on the claims of the Corbin Copper Company. Stephen R. Dow, president, has charge of the work.

New Jersey

SUSSEX COUNTY

A corps of engineers and assistants has been exploring the workings of the old zinc mine at Ogdenburg, which has been closed for a number of years. This has given rise to a report that the mine will be reopened.

North Carolina

JACKSON COUNTY

Consolidated Nickel Company—Machinery is arriving and being erected at the mine and smelter, near Webster

Oregon

GRANT COUNTY

Comer—These cobalt mines were not operated during 1908. However, it is expected that work will be resumed in 1909.

LANE COUNTY

Black Butte Quicksilver—J. B. Rouse, lumberman, has begun suit against this mining company to recover money which he claims is due him.

Le Roy—The management intends to resume work when patents are secured. The mine is equipped with air drills and a compressor plant.

Pennsylvania

BITUMINOUS COAL

Isabella-Connellsville Coke Company—This new company has secured control of practically all of the coal lands recently bought by J. V. Thompson, of Uniontown, in Fayette, Greene and Washington counties. The purchase is the largest area of coking coal in Pennsylvania, outside of that owned by the H. C. Frick Coke Company. The managers of the new company include John C. Bryden, who is president; Daniel Beach, L. G. McCrum, J. R. Nutt and other well known coal and iron men of Pittsburgh and Cleveland. Charles M. Schwab, of the Bethlehem Steel Company, is also said to be interested.

ANTHRACITE COAL

In the appeals of the Delaware, Lackawanna & Western and other companies from the decision of the Circuit Court, the Pennsylvania Supreme Court has reversed the decision of the lower court, and holds that there must be a reassessment of the property of the companies. The ground of the reversal is that the coal property was assessed for taxation at a higher percentage of its value than surface property. The appellants are, therefore, entitled to a reassessment on a uniform rate of valuation.

Plymouth Coal Company—This company has resumed possession and operation of the Dodson and Black Diamond collieries near Wilkes-Barre, the receiver having been discharged by the court. John C. Haddock, president of the Company, announces that the sum of 1c per ton of coal mined will hereafter be set aside as a trust for the benefit of employees who may be injured in the collieries.

Philadelphia & Reading Coal and Iron Company—This company's statement for February and the eight months of the fiscal year from July 1 to Feb. 28 is as follows:

	February	Eight Mos.
Earnings	\$2,497,771	\$22,803,425
Expenses	2,511,804	21,642,155
Net or deficit	Def \$ 14,038	\$ 1,161,270

For the first time this year the expenses for the month exceeded the receipts.

South Dakota

CUSTER COUNTY

The Westinghouse mica mill, near Custer, has resumed after a month's shut-down. No cause for the suspension has been given out. The raw product from this mine is shipped to Denver.

LAWRENCE COUNTY

Elliptic—Much interest has been aroused by the discovery of free-milling ore in the Maitland district. The ore is similar to that of the Homestake and intensifies the belief that the great Homestake ledge continues northwest at an increasing depth.

Homestake—At the regrinding plant hard quartz ore from the lower workings has been substituted for imported pebbles in the tube mills.

Definite information is now available in regard to the hydroelectric plant planned by the Homestake company. Work is to commence May 1, and the plant should be in operation by November, 1910. The capacity is to be 7000 horsepower and the power is to be used in the stamp mills, regrinding plant, the two leaching plants, the slimes plant, the machine shop, foundry and pattern shop. For the stamps alone, 2500 h.p. is required, while the compressor at the Ellison hoist will use 1000 more. The entire flow will be taken from Spearfish creek, four miles below Savoy, carried about six miles through a 7x6-ft. concrete-lined conduit with a fall of 700 ft. Eight tunnels varying from 2000 to 4000 ft. will be driven, for which work eight 5-h.p. electric drills will be used. The total cost is estimated at \$1,000,000.

Tennessee

Tennessee Copper—It is rumored that the directors will not declare a dividend covering the operations for the last six months. The matter of a contract for disposal of the sulphuric acid output of the company is still in the air.

Utah

BEAVER COUNTY

Cedar-Talisman—Sinking and drifting on the 500-ft. level is now under way and the property will be in shape to ship ore in the near future.

Utah Gold and Copper—The main tunnel on this property has entered the second vein 15 ft. without finding the wall. The upper tunnel shows a large amount of

lead ore and plans for the erection of a mill are now being made.

Beaver Combination—D. H. Ferguson of the Cedar-Talisman has been put in charge of this property also and development work is to be undertaken at once.

JUAB COUNTY

Ajax—The mine is shipping about 500 tons per month, part going to the Tintic plant and part to the Salt Lake smelters. Development work is being done on the 1000-ft. level.

Opex—The shaft has reached the 2000-ft. level, and will be continued for a distance of 500 ft. before drifting is started. The company is expecting to find the extension of the Centennial-Eureka ore-bodies.

King William—Development work on the 500- and 1000-ft. levels is being carried on through the Eagle and Blue Bell shafts.

Centennial-Eureka—The large body of ore found on the 2000 level resulted in continuing the sinking of the shaft to a depth of 2225 ft. A station is now to be cut and sinking of the shaft discontinued until an electric pump can be installed to handle the water, after which the shaft will be sunk to the 2500 level.

Utah Consolidated—The shaft of this Tintic property has attained a depth of 300 ft., and it has been decided to sink to the 400 level. The crosscut from the 300 level has gone a distance of 250 ft. and work is to be continued until the orebody is encountered.

Mammoth—A considerable tonnage of ore is being piled up by leasers at this mine awaiting satisfactory smelting arrangements.

Tintic Smelter—Ore is being received from outside the Tintic district from such properties as the Dalton & Lark, of Bingham, the Yellow Pine at Gene, Nev. and the Horn Silver at Frisco.

Bullock—Ore of the smelting grade has been encountered in the crosscut on the 210-ft. level.

Iron Hat—A contract has been let to Fred Wahlberg and Conrad Anderson to sink the shaft 100 feet.

SALT LAKE COUNTY

Bingham-New Haven—The General Engineering Company of Salt Lake has been awarded a contract for a 100-ton concentrating mill at Bingham. The mill is to be in operation by July 1.

Bingham Central-Standard—Shipping ore has been found in the last 100 ft. in the Mountain Maid tunnel which is being worked on company account. Leasers on

the Jeff Davis and Moscow tunnels are also taking out shipping ore.

SUMMIT COUNTY

Keystone—At a depth of 150 ft. in the incline shaft from the tunnel, 8 ft. of second-class ore have been found.

Tintic-Silver Crown—M. L. Snow, manager, announces the sale of 381,000 shares of treasury stock to Eastern men, and extensive development work will be started at once on the 540 acres controlled by this company.

TOOELE COUNTY

International Smelting—The contract for grading for the site of the new smelting plant in Pine cañon has been let to the Ely Construction Company.

Virginia

TAZEWELL COUNTY

Big Vein Pocahontas Coal Company—This company recently leased a large tract of coal land, on which are two small mines. One of these mines will be closed for the present; the other will be enlarged and provided with new machinery, increasing its capacity to 1500 tons daily. Thomas T. Boswell, Baltimore, Md., is president.

Washington

SNOHOMISH COUNTY

Arsenic Tariff—The Everett Chamber of Commerce adopted a resolution requesting congress to secure the imposition of a tariff on arsenic to the extent of at least 1½c. a pound on the mineral in the ores, and 2c. on white arsenic. F. H. Brownell, local attorney for the American Smelters Securities Company, states that the total consumption on this continent is about 7000 tons annually, and that the maximum production of 1500 tons at the Everett plant has led to a reduction in price by European producers who pay 30 per cent. less wages and have the advantage of cheap water transportation.

Monte Cristo—This property is reported sold to the American Smelters Securities Company, a transaction which in part is verified by its attorney, F. H. Brownell.

SNOHOMISH COUNTY—INDEX

Nonpareil Copper—This company will resume mining operations. Supplies are being packed up to the mine, and the drift in which a vein of copper ore was uncovered last fall will be continued.

Chewawa Lead and Smelting—At the mine on Red mountain a tunnel has been driven about 375 ft. Several orebodies have been crosscut. The outlook for the mine is very bright and the owners are greatly pleased with the progress made.

SNOHOMISH COUNTY—SILVERTON

Imperial—A strike of high-grade ore was made recently at this mine. The ore is gold-bearing.

West Virginia

KANAWHA COUNTY

Kanawha Collieries Company—This new company has bought the coal land and mine at Graham Mines, on the line of the Coal and Coke Railway. Electrical equipment and other new machinery will be installed at the mine. E. D. Leach, Mountsville, W. Va., is president of the new company.

MONONGALIA COUNTY

Arrangements are being made to open up the Millholland tract of 12,000 acres, owned by the Fairmont Coal Company.

Canada

BRITISH COLUMBIA

Crow's Nest Pass Coal Company—The coal-handling plant built by the C. O. Bartlett & Snow Company, of Cleveland, O., at the Michel mines, was started up in February, and is now handling the entire output of the mines. It is the largest plant of the kind in Canada. It is stated that this plant does the same work with 17 men in 12 hours that formerly required 48 men working 12 hours.

BRITISH COLUMBIA—ROSSLAND

Consolidated Mining and Smelting Company—A fire on the 400-ft. level of the Center Star mine did considerable damage to mine timbers before it was extinguished. A large force of men was engaged about 20 hours fighting the fire, under the supervision of W. H. Aldridge, managing director, R. H. Stewart, mine manager and M. E. Purcell, superintendent. Work has been resumed in the mine.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ended March 27 were as follows: Crown Reserve, 114,540 lb.; Cobalt Central, 40,000; Chambers-Ferland, 60,000; City of Cobalt, 53,592; Kerr Lake, 62,000; La Rose, 260,000; Nipissing, 258,770; Right-of-Way, 62,008; Temiskaming & Hudson Bay, 46,600; total 957,510 pounds.

Beaver—The annual meeting was held in Toronto March 29, when the shareholders granted authority to the directors to increase the capital stock from \$1,500,000 to \$2,000,000, in order to provide funds for continuing development operations, with the proviso that the new issue should not be sold at less than 10 per cent. of its par value.

Little Nipissing—Good ore has been struck in the vein on the Peterson Lake lease in drifting at the 160-ft. level. The vein, 10 in. wide, has become rich in na-

tive silver estimated at 2500 oz. to the ton.

Temiskaming—A vein with good silver contents about 10 in. in width has been discovered at a depth of 250 ft. where the drift was continued into the Gans location.

ONTARIO—GOWGANDA DISTRICT

Bartlett—H. T. Pemberton, manager, recently brought samples of ore to Toronto from vein No. 1 on the southwest claims, weighing about 900 lb. Two specimens, weighing over 150 lb. each are almost solid calcite and silver.

NOVA SCOTIA

Dominion Coal Company—This company and the Dominion Steel Company, on March 30, entered into two agreements with a view to the settlement of the dispute over the coal contract which is involved in the pending litigation, the coal company at the same time making a payment of \$2,750,000 on account of the damages claimed by the steel company. The agreements are given at length in the *Montreal Gazette* of March 31; the substance is as follows: The coal contract of Oct. 20, 1903, is declared to be in full force and effect and the steel company is permitted within 10 days to deliver to the coal company notices of its requirements of coal for April, May and June, 1909, not exceeding 80,000 tons per month.

The steel company may in the pending action recover damages suffered from Aug. 1, 1906, to date, but no damages shall be assessed therein for the unexpired term of the contract. Neither party shall be precluded from bringing action for any breach of the contract which may hereafter occur.

The steel company is to file a statement of the particulars of its claim, and within two months also a complete detailed supplementary statement of all damages caused by the short deliveries of coal by the coal company, or the partial shutting down of the steel company's works by reason thereof, the coal company to have four months (exclusive of delay caused by the steel company) to verify the particulars of the claim, and for that purpose to have the right to examine the works, books, accounts and documents of the steel company.

The payments on account shall be without prejudice to the right of the coal company to dispute any of the items of the steel company's claim.

After the conclusion of the examination an amicable settlement of the litigation is to be reached, if possible, before proceeding to assess the damages claimed before the referee appointed by the court.

YUKON—DAWSON

Much activity prevails, in connection with the opening of the mining season. Many people are coming in from "the outside," chiefly by stage or private conveyance from Whitehorse, while scores of teams

are hauling supplies to the various creeks. Mining companies are hurrying their preparations for either ordinary hydraulic or dredging. The Guggenheim interests, especially, are preparing for extensive operations throughout the ensuing season; beside putting on hundreds of men at mining, they will build 12 miles of new ditch on Bonanza creek. Other power schemes are being worked out and more dredging enterprises will be undertaken than in any previous year.

Mexico

CHIHUAHUA

Burns & Daly—A strike of good copper ore is reported about 15 miles from Ahumada. A small shipment was recently made to the El Paso smelter. This property was denounced last year by J. L. Hollister, but is now owned by Burns & Daly.

Mexicana—A good grade of zinc ore is being shipped to the Kansas smelters. The property is 20 miles west of the Burns & Daly mine.

Mexico Northwestern Railway Company of Canada—S. F. Pearson, president; E. D. Kenna, Enrique C. Creel and Walter Gow, vice-presidents. This company has lately been organized and incorporated in Canada to build and operate railroads in northern Mexico. Capital stock, \$40,000,000.

MEXICO

Esperanza—February: Mill, 22 days, crushed 11,569 tons of dry ore. Concentrates and 31 tons of ore shipped to smelter. Estimated value of bullion produced, \$116,809; estimated value of concentrates, \$31,569; receipts from rents and other sources, \$438. Total, \$148,816. Less—Working expenses, including development, marketing of bullion, and freight and treatment charges on concentrates shipped to smelter, \$93,980; allowance for depreciation of plant, \$2500; consulting engineers' fees and New York office expenses, \$2187; total, \$98,667. Balance, \$50,149. Estimated profit, \$10,026. Of this there has been expended on construction account \$2136. Feet of development work, 968. Low profit is due to smaller tonnage of ore treated, arising from the continued changing over from the old to new mill, and the short month.

SONORA

Green-Cañanea—Production in March was 4,000,000 lb., compared to 3,834,000 in February and 3,848,000 in January.

South America

BRITISH GUIANA

Exports of gold for the two months ended Feb. 28 were 7417 oz. bullion in 1908, and 8881 in 1909; an increase of 664 oz. The bullion reported this year was equal to \$130,609, or 6754 oz. fine gold. Exports of diamonds for the two months were 307 carats, of \$1846 value.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, April 7—The anthracite labor question is still unsettled, although no strike nor lockout has taken place. The companies agreed to a continuance of work under the existing agreement for a short time, or until further negotiations could be carried out, and work is continuing at the mines as usual. It is not expected, however, that this arrangement will continue long and a decision one way or the other will undoubtedly be forced as soon as possible. A conference between representatives of the operators and those of the mine workers is being held today, but may continue for several days before any result is reached. It is undoubtedly the purpose of the mine workers to prolong the negotiations as much as possible; and it is equally the determination of the operating companies to tolerate as little delay as they can. It is not impossible that matters may be settled at the conference now in progress.

The Eastern bituminous trade continues quiet. A fair amount of business is being done, but nothing like that of 1907. The demand for steam coal increases slowly.

In the West reports are rather more cheerful, a better demand for steam coal being noted, and mines are working more steadily throughout Indiana and Illinois.

The coke market has rather suffered from overproduction, and this week the Frick Coke Company shut down 600 ovens, while independent producers banked 500 more in the Connellsville region.

Panama Contracts—The contract for 400,000 tons of coal for the Panama railroad during the coming year has been awarded to W. C. Atwater & Co. at \$2.39 per ton for Pocahontas coal, f.o.b. Newport News.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to March 27, short tons:

	1908.	1909.	Changes.
Anthracite	1,269,280	1,164,353	D. 44,327
Bituminous	8,095,053	8,367,837	I. 254,224
Coke	1,718,262	2,371,772	I. 657,420
Total	11,020,595	11,928,962	I. 908,017

Total increase this year to date was 8.2 per cent.

The total coal production of Ohio in 1908 is reported at 26,268,230 short tons. This compares with 32,365,949 tons in 1908, showing a decrease of 6,097,710 tons, or 18.8 per cent. Of the total last year 21,621,046 tons, or 82.3 per cent., were mined by machines.

New York

ANTHRACITE

April 7—The market continues quiet and business is going on steadily as though there was no controversy impending. Trade is about as usual and domestic sizes are in abundant supply. Steam sizes are still rather scarce.

Prices under the April circular are \$4.25 for lump and \$4.50 for egg, stove and chestnut f.o.b. New York harbor points. For small steam sizes prices are nominally unchanged as follows: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points. Advances from 10c. per ton up are still asked by commission merchants.

BITUMINOUS

The soft-coal market remains quiet, with very little change from the last report. Contract making continues slowly and probably about one-half of the yearly contracts usually closed in this market have been concluded, most of them at prices a little under last year. Current business may be said to show a little improvement; that is, more coal is being sold than there was a year ago. It is noticed that orders coming in are generally accompanied by a hurry clause indicating that stocks in the hands of consumers are very low. The different consuming districts are running about even, the far East, the Sound and New York harbor being about the same. All rail trade is better than Seaboard, as it has been for some time. Transportation is good and cars are in plentiful supply. There is no stock of coal pressing on the market anywhere, as producers have fallen into the habit of shipping coal only on orders.

Prices continue low. Good grades of steam coal can be had at about \$1.25@1.35 at mine; poorer grades as low as 90c. @ \$1 at mines. Gas coal brings from 85c. @ \$1.10 for 34-in.; 75c. @ 85c. for run-of-mine and 60c. @ 65c. for slack, all at mines.

In the Coastwise trade vessels are still hunting for charters. Rates are unchanged from last week's report, although a few of the larger boats have shaded prices 5c. in order to get full cargoes.

Birmingham

April 5—The coal market in Alabama is quiet and the production is off considerably. More mines have been shut down. The starting up of a couple of batteries of coke ovens is the only encouraging feature

for the week. One of the principal traffic companies in the district reports that the business has fallen off at the mines and that the greater portion of the product being handled right now is for company use.

Coke is in a little better demand than it has been and there is hope of a continuance of the improvement.

Chicago

April 5—Except on lump sizes the shipments of Illinois and Indiana coals are well regulated to demand in the Chicago market now, and prices consequently hold up well. The demand for domestic coals is small and decreasing; for steam coals it is steady and increasing slowly. Fine coals are in growing demand, but the supply is so large from Western mines that no large increase in price is probable. Screenings now bring \$1.40@1.60; run-of-mine sells for \$1.65@1.75, and lump or egg for \$1.75@2.30.

Eastern coals in general continue strong, smokeless especially holding up close to circular prices, in contrast to the demoralization caused by overshipments a few weeks ago. Neither lump nor run-of-mine smokeless is in too great supply now, operators having generally restricted their shipments. Smokeless finds fair sale at \$3.20@3.45 for lump and \$3.05@3.15 for run-of-mine. Hocking is somewhat weak; too much has been received for stability of the list price of \$3.15, which has been cut to as low as \$2.75, most sales being made at \$2.90@3. Youghiogheny is in quiet, steady movement at \$3.15 for 34-in. gas coal; Pittsburg No. 8 brings \$2.65@2.75 for the same size.

Anthracite moves well under the April discount, retailers and consumers showing a disposition to lay in stocks early, and sales for immediate consumption are fairly good.

Cleveland

April 6—The coal trade is improving a little, dealers reporting a better demand for steam coal. Shipments from mines are not rushed, and there is little demurrage coal on the market.

Little is doing yet in the Lake trade, and it is evident that there will be a late opening. Reports from the Northwest are that stocks are still large.

Indianapolis

April 6—Indiana coal-mine operators say that the winter season is practically

at an end, but that manufacturers are ordering larger quantities of steam coal regularly. From this time on the operators will begin to provide for the demand that usually comes in June and August for storage supplies from dealers.

An order has been entered in the Federal court directing John K. Seifert, as receiver for the Indiana Southern Coal Company, to enter into a contract with the American Steel and Wire Company to supply that company with 250 to 300 tons of coal a day from April 1, 1909, to April 1, 1910. The contract price is 87½c. per ton.

Pittsburg

April 6—Considerable new business has been taken during the past few days at cut prices. Producers are still quoting on the basis of \$1.15 for mine-run coal, but contracts have been closed at \$1.10 and some as low as \$1.05 a ton. On a large contract even this rate might be shaded. The most important contract of the week was taken by the Pickands-Magee Company calling for one-half of the year's fuel supply for the Grand Trunk Railroad, or 150,000 tons, deliveries to be made at Conneaut Harbor, beginning on May 1. The coal will come from the Bessemer district and will insure the steady operation of the Pickands-Magee Company's mines. Shipments to Lake ports for the northwestern markets have been begun on a small scale and several cargoes have gone out in small boats from Cleveland. The railroad mines in the Pittsburg district are not being operated to more than 60 per cent. and there is a scramble for all the business going. The river mines continue in full operation and a fairly large tonnage of coal has been accumulated in coal boats and barges.

Connellsville Coke—The coke trade is discouraging. Fully 1200 ovens have been put on the idle list within the past 10 days and others likely will go out this week. The H. C. Frick Coke Company has closed about 600 ovens. A number of blast furnaces that receive coke from the Connellsville fields have been blown out and others are scheduled to go out before May 1. Favorable progress is being made in the project to form a combination of all the coke interests outside of the big corporation. Furnace coke for spot shipment is still selling at \$1.50@1.60; some concerns are holding for \$1.75 on contract coke; it is believed \$1.60 can easily be done for deliveries running to July 1. Foundry coke remains at \$1.90 for spot and \$2.02.15 on contract. The Courier records the production in both fields at 237,741 tons. The shipments were 8787 cars as follows. To the Pittsburg district, 3270, to points west of Pittsburg, 4611, to points east of Connellsville, 867 cars.

Foreign Coal Trade

United States Coal Imports—Imports of coal and coke into the United States, two months ended Feb. 28, long tons:

	1908.	1909.	Changes.
Anthracite.....	11,914	3,114	D. 8,800
Bituminous.....	305,724	206,103	D. 97,621
Total coal.....	317,638	211,217	D. 106,421
Coke.....	31,134	28,594	D. 2,540

Canada furnished this year 166,504 tons coal and nearly all the coke; Australia, 31,474 tons coal. Imports are chiefly on the Pacific coast.

United States Coal Exports—Exports of coal and coke from the United States, with coal furnished for the use of steamships at all ports, two months ended Feb. 28, long tons:

	1908.	1909.	Changes.
Anthracite.....	301,267	297,096	D. 4,171
Bituminous.....	1,222,038	1,000,130	D. 221,908
Total exports...	1,523,305	1,297,226	D. 226,079
Steamer coal.....	982,468	871,306	D. 111,162
Total.....	2,505,763	2,168,532	D. 337,231
Coke.....	131,016	155,917	I. 24,901

Canada took this year 879,874 tons, or 67.8 per cent. of the total coal. The coke goes chiefly to Mexico and Canada.

French Coal Production—The total coal production of France for the years named was, in metric tons:

	1907.	1908.	Changes.
Coal mined.....	36,390,250	36,770,211	D. 100,039
Coke made.....	2,107,342	1,384,760	D. 152,582
Briquets made....	2,192,715	2,076,881	I. 115,834

The change in the total coal production was unimportant.

French Coal Trade—Official statement of fuel exports and imports in France, full year, metric tons:

Exports.	1907.	1908.	Changes.
Coal.....	1,146,400	1,092,106	D. 73,294
Coke.....	109,840	150,783	D. 19,943
Briquets.....	113,410	129,369	I. 15,959
Total.....	1,448,650	1,372,258	D. 76,392
Imports:			
Coal.....	14,808,967	14,732,530	D. 136,437
Coke.....	2,175,715	1,836,380	D. 349,335
Briquets.....	694,120	1,012,920	I. 318,200
Total.....	17,738,802	17,581,200	D. 167,602

Exports in 1908 included 115,697 tons coal and 53,217 tons briquets furnished to steamships in foreign trade.

Austrian Coal Production—Coal production in Austria for the full year was as follows, in metric tons:

	1907.	1908.	Changes.
Coal.....	13,850,420	14,091,131	I. 240,711
Brown coal.....	26,262,110	26,669,709	I. 407,599
Total mined....	40,112,530	40,760,840	I. 648,310
Coke made.....	1,870,189	1,915,414	I. 36,225
Briquets made....	295,145	339,686	I. 44,541

Of the briquets made in 1908 there were 191,860 tons from brown coal, or lignite.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on March 27: Best Welsh steam, \$3.48; seconds, \$3.30; thirds, \$3.24; dry coals, \$3.48, best Monmouthshire, \$3.06; seconds, \$3; best small steam, \$2.22; seconds, \$2.04. All per long ton, f. c. b. shipping port.

Iron Trade Review

New York, April 7—The iron and steel markets show a variable improvement; while still slow in some directions there is a manifest advance in others.

Pig iron has been rather quiet. Early in the week one or two considerable contracts were reported for basic pig for Western delivery at prices not made public. There is considerable inquiry in the East for foundry iron, but less in that line is doing in the West. Prices are rather indefinite, but those for foundry have been seriously affected by the action of Southern makers in taking contracts as low as \$11 and even \$10.50 Birmingham for No. 2 foundry.

In finished material there has been a great deal of activity in structural steel and in bars, while plates have sold rather freely. The structural market has been especially active and some large contracts for buildings have been placed. An improvement in the demand for nails and other minor products is reported, indicating an increase in general building throughout the country.

While new orders for rails are still scarce, the railroads are taking on a good deal of bridge material, and some orders for equipment are reported.

Bethlehem Steel Company—The report of this company for 1908 shows that the total orders received for the year were \$14,458,097, a decrease of \$1,156,021 from 1907. Net income was \$2,192,355, a decrease of \$46,602; net surplus over charges and depreciation, \$386,864, a decrease of \$1,231,925. The uncompleted orders on hand Dec. 31, 1908, amounted to \$7,592,502, a decrease of \$992,163 during the year. The number of employees at the close of 1908 was 8615, being 1168 less than at the end of the previous year.

Baltimore

April 6—Exports for the week included 776 tons of steel rails and rail fastenings to Vera Cruz. Imports included 1508 tons ferromanganese and 3 tons silico-spicgel from Liverpool; 10,500 tons iron ore from Cuba.

Birmingham

April 8—An encouraging feature in the Southern pig-iron market is the fact that inquiries are coming in. The market is quite dull. The sale of another good lot of iron for use in manufacturing cast-iron pipe is reported in this district, an Eastern pipe concern making the deal. The quotations are between \$11@11.50 per ton, No. 2 foundry. Two or three of the larger companies are holding their iron at \$11.50 per ton, and one company in particular is said to have notified some of the larger consumers in the North that there is no necessity to sacrifice the product, and that

the carrying of the same until better times would not be difficult. There has been a little accumulation of iron in this territory, but not to any alarming extent. There has been no further curtailment of production recently.

The rumors still prevail that there is to be a shutdown of the steel plant of the Tennessee company in the next few days, but nothing definite is given out at the local offices.

The cast-iron pipe plants in the Birmingham district have their hands full, and shipments are steady.

Chicago

April 5—The pig-iron market continues to wait on the laggard melter who is postponing his buying until he feels sure that the bottom of the market has been reached. Buying is in small lots for second and third quarters at \$10.50@11, Birmingham (\$14.85@15.35 Chicago), for Southern No. 2, and \$16@16.50 for Northern No. 2. On much business \$11 is obtained for Southern and on some still more, depending on conditions of delivery. For a good-sized contract on second-half delivery a very low price, doubtless, could be made. Inquiries continue numerous for second-half tonnage.

The steadiness of Northern iron compared with Southern is noteworthy. Iron from local furnaces has a fairly assured market for special purposes, as has Northern charcoal, which sells at \$19.50@20 in the small lots demanded.

Iron and steel products find slightly improving conditions from week to week, railroad supplies, plates, bars and sheets being in good demand and structural material quiet. Coke is stationary, the best Connellsville bringing \$4.75@4.85, Chicago.

Philadelphia

April 7—The pig-iron market is still in a depressed condition. Foundrymen will not buy much ahead, as they are still looking for bottom prices to come. The only people who seem to want much iron just now are the cast-iron pipe makers, and they want it cheap. Southern furnaces have further demoralized the trade by their hunt for orders at any price.

Steel Billets—Nothing doing, as buyers are looking for lower prices still.

Bars—Some large orders are reported placed at low prices. Store trade is much better than a month ago.

Structural Material—Business is active. Some large contracts are being talked over and will be placed soon, as low prices have been named. Small orders are coming in, making up a big total. Everybody seems to be getting ready to build.

Nails—The demand for nails and other supplies for small building is increasing fast, indicating a lot of work in that line.

Scrap—Dealers are on the hunt for customers. Most of them are pretty well loaded, and are anxious to get rid of some of the stock they are carrying. Buyers, for the most part, are in no hurry. Between the two prices are demoralized.

Pittsburg

April 6—A large volume of new business has been placed during the past few days and some important contracts are about to be closed. Orders so far have been for small tonnages only, but the aggregate has been large, and some interests have increased their production. The Republic Iron and Steel Company is operating all of its plants in the Youngstown district this week and today blew in No. 2 furnace of the Hazleton group, the other two having been in operation for several months. The company's Hannah furnace at Youngstown, is scheduled to go in blast next week. This will practically double the company's pig-iron production in the North and indicates a rapidly increasing trade in finished iron and steel products. It was intimated by the representative of a large steel interest today that several large contracts for structural steel, plates, merchant pipe and rails are to be awarded within a few days. Despite the low prices established on Feb. 19, there has been considerable shading by independents while the Steel Corporation subsidiary companies have been strictly adhering to the rates. It is now planned, according to reports, for the Corporation to go after all business, quoting below the lowest prices named by independent producers. The leading bar-iron producer has cut the price of iron bars \$1 a ton and is now quoting 1.35c., Pittsburg, and is strictly observing the 1.20c. rate for merchant-steel bars. For western shipments prices are lower than heretofore quoted, but all western orders are supplied from mills in the Chicago territory. The wire concerns are not booking much new business as former prices are being quoted and jobbers and large consumers are so confident that prices will be cut that they are keeping out of the market, buying only for urgent needs. The National Tube Company continues to operate its plants in the Pittsburg district at about 80 per cent. and is still booking new business.

Pig Iron—The only new business of importance was the closing of a contract for 3600 tons of chill-cast bessemer by the Crucible Steel Company of America. The price is not given; the iron will be supplied by the Carnegie Steel Company from the Clairton furnaces. The Carnegie Steel Company blew in another Edgar Thomson blast furnace, the eighth of the group of 11, and is now operating 36 of its 59 blast furnaces. The bessemer average for March was \$15.437, Valley furnaces, a decline of \$0.438 from the

previous month. The basic average was \$14.937, Valley, a decline of 25c. Pig-iron quotations are nominal as follows: Standard bessemer, \$15@15.25; malleable bessemer, \$14.50@14.75; basic and No. 2 foundry, \$14.50; gray forge, \$13.50, all at Valley furnaces; freight to Pittsburg district, 90c. per ton.

Steel—Billet sales at the established price of \$23, Pittsburg, are few and reports that this price is being shaded cannot be confirmed. Sheet-bars are quoted at \$25.50, delivered, but sales have been made lower. Merchant-steel bars are still 1.20c., and plates, 1.30c.

Sheets—Prices are firm and some new business is being booked. Black sheets are 2.30c. and galvanized 3.30c. for No. 28 gage.

Ferro-Manganese—Prices are a trifle higher; \$43.50@44 is quoted for prompt delivery at Pittsburg.

Foreign Trade in Iron and Steel

Iron and Steel Exports—Exports of iron and steel, including machinery, from the United States for the two months ended Feb. 28 are valued by the Bureau of Statistics of the Department of Commerce and Labor at \$27,531,617 in 1908, and \$21,276,547 in 1909; a decrease of \$6,255,040, or 22.7 per cent. Leading items of export, in long tons:

	1908.	1909.	Changes.
Pig Iron.....	4,222	5,362	I. 1,740
Billets, ingots & blooms	27,008	15,934	D. 11,064
Bars.....	9,439	9,889	I. 390
Rails.....	25,254	33,764	I. 8,510
Sheets and plates.....	16,480	19,891	I. 3,411
Structural steel.....	20,407	15,813	D. 4,594
Wire.....	23,300	20,115	D. 3,185
Nails and spikes.....	7,990	8,353	I. 363
Pipe and fittings.....	15,531	16,981	I. 1,450

The increases and decreases in these quantities were almost evenly divided.

Iron and Steel Imports—Imports of iron and steel and of machinery into the United States two months ended Feb. 28 were valued at \$3,774,291 in 1908, and \$3,628,746 in 1909; decrease, \$145,545, or 3.9 per cent. Leading articles of import were, in long tons:

	1908.	1909.	Changes.
Pig iron.....	23,418	20,643	D. 2,775
Scrap.....	1,076	1,064	D. 12
Billets, blooms, etc.....	1,107	2,018	I. 911
Bars.....	8,069	9,115	D. 4,366
Wire-roads.....	2,066	1,834	D. 232
Timber.....	10,201	7,463	D. 2,738
Sheets and plates.....	470	502	I. 32

The only increases this year were small ones in sheets and in ingots and blooms.

Iron Ore Movement—Imports and exports of iron ore in the United States, two months ended Feb. 28, long tons:

	1908.	1909.	Changes.
Imports.....	137,753	166,982	I. 29,229
Exports.....	10,984	11,799	I. 816

Of the imports this year 114,205 tons were from Cuba; the balance from Newfoundland and Spain.

Imports of manganese ore, two months ended Feb. 28, were 53,713 tons in 1908, and 35,000 in 1909; decrease, 18,653 tons.

Metal Market

New York, April 7.—The metal markets show some degree of improvement, but no considerable changes for the week.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Feb., 1909.	\$ 8,860,814	\$ 3,576,413	Exp. \$5,284,401
" 1908.	1,967,597	2,847,133	Imp. 879,536
Year 1909.	16,736,170	5,906,536	Exp. 9,729,634
" 1908.	2,411,797	13,646,617	Imp. 11,234,820

Treasury notes of \$10.....	1,193	4,956,907
U. S. notes.....	7,552,169	339,128,847
Nat. bank notes.....	22,816,033	661,591,582
Total.....	\$311,931,018	\$3,086,684,616
Total, April 1, 1908.....		3,060,450,734

Population of the United States April 1, 1909, estimated at 88,567,000; circulation per capita, \$34.85. In addition to amount in Treasury the Government has \$58,152,737 on deposit in National banks.

Gold—No change in prices in the open market in London is reported, quotations being 77s. 6d. per oz. for bars and 76s. 4d. for American coin. Most of the gold offered this week was taken by the Austrian government, presumably for use in its settlement with Turkey.

Platinum—Dealers quote \$23@24 per oz. for refined platinum, \$26 for hard metal and \$19@21 for scrap. Business is improving and sales are freer than they have been.

Silver—The market appears to have reached a period of dullness, with no special inquiry or speculative tendency in sight. It does not look as if any great fluctuation in price were liable to happen at present.

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125¢ below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—Although business has quieted down, the market has not lost any ground during the week. It is generally recognized that consumption the world over is slowly, but surely, increasing, and that the disparity between supply and demand is proportionately diminishing. All of the agencies are offering electrolytic freely at 12½¢, delivered, 30 days, which is equivalent to a little less than 12½¢, cash, New York, and this price has been shaded a little on transactions. The close is steady and unchanged at 12½¢@13¢ for Lake copper; 12½¢@12½¢ for electrolytic in ingots, cakes and wirebars. The average of the week for casting copper is 12½¢@12½¢.

Copper sheets are 16½¢, base for large lots. Full extras are charged, and higher prices—up to 18¢—for smaller quantities. Copper wire, 14½¢, base, carload lots at mill.

The London market has shown a firm undertone during the week, fluctuating within narrow limits. The close is steady at £57 5s. for spot, £57 17s. 6d. for three months standard.

Statistics for the second half of March show a decrease in the visible supplies of 1000 tons.

Refined and manufactured sorts we quote: English tough, £61 10s.; best selected, £60 10s.@61 10s.; strong sheets, £72 10s.@74 10s.

Copper exports as reported by the Bureau of Statistics for the two months

ended Feb. 28 were 36,542 long tons; for March they are estimated at 21,160 tons, making a total of 57,702 tons for the three months.

Stocks of copper usually included in visible supplies were, on April 1: Great Britain, 37,930 long tons; France, 5920; afloat from Chile and Australia, 7500; total, 51,350 tons, a decrease of 1020 tons from the March 15 report.

Tin—The transactions in the London market have become smaller and the tone somewhat softer than it was during last week. Quotations have declined somewhat and close at £133 2s. 6d. for spot, £134 2s. 6d. for three months.

Some business was done in the domestic market by speculators, presumably for London account, but the demand on the part of consumers, especially for forward delivery, still leaves much to be desired. Spot metal at the close can be bought at about 29¼¢ per pound.

Statistics for the month of March show an increase in the visible supplies of 100 tons.

Lead—Business continues in fair volume at 3.95¢. St. Louis, 4.10¢. New York.

The London market has been rather easier this week, the close being cabled at £13 8s. 9d. for Spanish lead, £13 11s. 3d. for English lead.

Spelter—There is a great deal of reluctance on the part of sellers to part with their metal at present prices, due to the proposed tariff on zinc ores. It took only a slightly better inquiry to affect prices, and though the orders placed were relatively of small volume, the market has advanced at the close to 4.80¢@4.82½¢ New York. 4.65¢@4.67½¢ St. Louis.

Quotations for spelter in New York, April 1, were 4.75¢@4.77½¢; 2 and 3, 4.75¢@4.80¢; 5 and 6, 4.77½¢@4.82½¢; 7, 4.80¢@4.82½¢ cents.

Base price of sheet zinc is now 6¼¢, per lb., f.o.b. La Salle-Peru, Ill., less 8 per cent. discount.

The London market is unchanged at £21 7s. 6d. for good ordinaries, £21 12s. 6d. for specials.

According to a newspaper report, the earnings of the Lanyon-Starr Smelting Company in 1908 were about 4 per cent. on its preferred stock of \$250,000.

Other Metals

Antimony—Business continues extremely dull. In the absence of sales prices are nominally unchanged at 8¢ per lb. for Cookson's, 7½¢ for Hallett's, and 7½¢ for ordinary brands.

Aluminum—Quotations are unchanged at 22@24¢, base for No. 1 ingots; 33@34¢, base for sheets.

Quicksilver—The market in New York is quiet and unchanged at \$45@46 per flask of 75 lb. San Francisco prices are nominal at \$44@45 for domestic orders, and \$2 less for export. The London quotation has been reduced 5s., and is now £8 2s. 6d. per flask.

Nickel—Large lots, contract business, 40@45c. per lb. Retail, spot, from 50c. for 200-lb. lots up to 55c. for 500-lb. lots. The price for electrolytic is 5c. higher.

Cadmium—Current quotation 75c. per lb., in 100-lb. lots, at Cleveland, Ohio.

Magnesium—Quotations for this metal are \$1.25 per lb., New York, in 100-lb. lots; for 5-lb. lots, \$1.40 per pound.

Imports and Exports of Metals

Exports and imports of metals in the United States, two months ended Feb. 28, are reported as follows, in the measures usual in the trade:

Metals.	Exports.	Imports.	Excess.
Copper, long tons	36,542	21,401	Exp. 15,141
Copper, 1908.....	59,352	14,312	Exp. 45,040
Tin, long tons.....	56	5,938	Imp. 5,882
Tin, 1908.....	60	3,212	Imp. 3,152
Lead, short tons	13,840	17,958	Imp. 4,118

Chrome ore.....	6,801		Imp. 6,801
Chrome ore, '08			

Copper, lead and nickel include the metal contents of ores, matte, bullion, etc. The exports given include reexports of foreign material. Imports of zinc ores in 1909 included 2929 tons calamine and 10,313 tons other ores, against 3648 and 2637 tons, respectively, last year. Chrome ore was not reported last year.

Zinc and Lead Ore Markets

Platteville, Wis., April 3—The highest price paid this week for zinc ore was \$39; the base price for 60-per cent. zinc was \$37.50@38 per ton. For 80-per cent. lead ore, \$19 per ton was paid.

SHIPMENTS, WEEK ENDED APR. 3

Craups.	Zinc ore, lb.	Lead ore, lb.	ore, lb.

Year, to Apr. 3.....	26,241,394	627,580	2,429,850

In addition to the above there was shipped to the American Zinc Ore Separ-

ating Company 273,300 lb., and to the Joplin Separator Works, 174,600 lb. zinc concentrates.

Joplin, Mo., April 3—The highest price reported was \$41.50 per ton for sulphide zinc ore assaying 63.5 per cent. zinc sold on a \$38 base. Additional sales were made this week on a \$38 base, and the bulk of the large purchases were made on a \$37.50-base price, with a less amount selling at \$37@36.50 base, and but a few scattering lots on a \$36 base. Zinc silicate ore was lower in price, with no competition, very nearly all the purchases being on a base of \$17 per ton of 40-per cent. zinc, with a few on an \$18 base. The highest reported was, however, \$25 for one bin assaying 47 per cent. on an \$18 base. The general high price was \$20@21. The average price, all grades, was \$34.58. Lead continues upward, with offerings as high as \$55, an advance of \$1.50 per ton. The base price was generally \$54 per ton of 80-per cent. lead. The average price, all grades, was \$52.82 per ton.

The week's shipment foots up the second-largest total tonnage of the year, in zinc, some of the large purchases of two and three weeks ago being loaded out. The car situation has been troublesome, but is better now.

NOTE—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

Chemicals

New York, April 6—The chemical market is exceptionally dull and inactive.

Copper Sulphate—Prices are at a standstill at \$4.60 per 100 lb. in carload lots and \$4.85 per 100 lb. for smaller quantities.

Arsenic—White arsenic is now quoted at 27½c. per lb. A dull market prevails.

Nitrate of Soda—The market is exceptionally dull and heavy. Prices are 2.15@2.17c. for both spot and futures.

The position of nitrate in the United States on April 1 is reported as follows, in long tons, by Messrs. Mortimer & Wisner, New York:

	1908.	1909.	Changes.
Stocks, Jan. 1.....	5,900	9,340	I. 3,240
Imports 3 months.....	53,300	104,800	I. 51,500
Total Supplies.....	59,200	113,940	I. 54,740
Deliveries 3 months.....	61,550	99,990	I. 48,340
Stocks, Apr. 1.....	7,550	13,950	I. 6,400
Afloat for U. S.....	80,000	60,000	D. 20,000

Quantities afloat include all cargoes due to arrive at United States ports before July 15 next.

Phosphates—Exports of Florida phosphates through the port of Savannah in February are reported by J. M. Lang & Co., at 5025 tons, all to Germany.

Imports and Exports—The imports and exports of chemicals and raw materials in the United States, two months ended Feb. 28, were as follows:

	Imports.	Exports.	Excess.
Copper sulph. lb.	1,318,978	E.	1,318,778
Blanch, lb.	12,814,773	I.	12,814,773
Potash salts, lb.	69,319,942	1,108,105	I. 68,210,837
Soda salts, lb.	2,055,204	94,002	I. 1,961,202
Acetate lime, lb.	16,704,200	E.	16,704,200
Nit. of soda, tone	41,254	1,035	I. 40,219
Phosphates, tone	425	119,005	E. 118,580
Sulphur, tons.	4,762	6,537	E. 1,775
Pyrites, tons.	93,946	I.	93,946

Exports include reexports of foreign material. Estimating sulphur contents of pyrites, the total sulphur imported was approximately 42,340 long tons.

Mining Stocks

New York, April 7—The general stock markets throughout the week have shown a good deal of strength and prices have advanced with only some slight reaction. The bull market seems to be pretty well established for the present.

There have been all sorts of rumors about the expected decision of the Supreme Court on the commodities clause, but these seem to have been without foundation and were doubtless circulated for the purpose of depressing certain stocks.

On the Curb the copper stocks were generally strong and in good demand, but fluctuations were not very large in amount. There were heavy sales of Nevada Consolidated and one or two other stocks at slight advances in prices. The Nevada gold stocks were only moderately

Industrials

The Wagner Electric Manufacturing Company announces the removal of its district office in Pittsburgh to the Lewis block, and the appointment of Ludwig Hommel as district manager.

Stromberg-Carlson Telephone Manufacturing Company advises the appointment on March 1 of H. C. Sleinin to the dual position of sales manager and advertising manager.

The new Johnson breaker of the Scranton Coal Company, at Olyphant, Penn., the main engine and most of the cross drums will be equipped with rope drives on which American transmission rope will be used exclusively. There will be 46 drives.

The Wood Drill Works, of Paterson, N. J., is distributing through its New York City and Boston representatives, Harold L. Bond Company, a folder giving the detailed points in the construction of the Wood rock drill with the advantages in these special features.

Among the recent orders taken by the Crocker-Wheeler Company, of Amper, N. J., is one for a 250-k.w. motor-generator set for the Tennessee Coal, Iron and Railroad Company, at Ensley, Ala. It will consist of a 250-k.w., 275-volt, d.c. generator, driven by a 6600-volt, 3-phase, 25-cycle synchronous motor, and will be used as an exciter. Another order is one for about 50-h.p. of small elevator motors purchased by the Houghton Elevator and Machine Company, of Toledo, Ohio. Yawman & Erbe, of Rochester, N. Y., have also placed orders for a number of 2-to 5-h.p. motors for use on some of their specialties.

The Power and Mining Machinery Company, of Cudahy, Wis., reports the following sales of mining machinery: Through the International Machinery and Engineering Company, of Mexico City: Minera de Tenamache—One 10-stamp mill, with crushers and 5-ft. x 18-ft. tube mill; Cia. Minera la Victoria y Topada—One 10-stamp mill complete, with 5-ft. x 18-ft. tube mill; Cia. Minera San Antonio—One 10-stamp mill, with 5-ft. x 14-ft. tube mill. Through the San Francisco office, Harris Mining and Milling Company, of Nevada—Ten-stamp mill equipment; Seoul Mining Company, of Corea—One 5-ft. x 22-ft. tube mill.

To users of power machinery, simplicity is a most desirable feature. For many years the centrifugal pump, which is the simplest type of pumping machine, undeveloped and crude in design and construction, was used only for pumping against comparatively low heads, and where economy was of secondary importance. In recent years, however, a great advance has been made in the design and construction of centrifugal pumps; and the higher degree of economy now secured, both at high and low heads, also the use of the turbine pump constructed in multiple stages, have brought the centrifugal pump into general use for a great variety of purposes. Formerly it was not thought possible to operate centrifugal pumps at heads greater than 20 or 30 ft., with any degree of economy, but with the great advance in design the D'Olier Engineering Company, Philadelphia, Penn., is now able to develop economical pumps with heads up to nearly 200 ft. in a stage. Catalog T on application.

The Baldwin lamp consists of a water tank on top into which is screwed the carbide container. A pipe projects from the bottom of the water tank into the carbide container, and a wire of the exact size to permit just the required amount of water to flow down the pipe and on to the carbide passes through this pipe, projecting above the top. Should the flame become low, rotating this wire will, of necessity, clear the water tube, thus keeping the lamp burning brightly. No springs, valves nor regulating devices to get out of order, only a pipe and a wire through it to keep it clean; any miner can learn to turn the wire, and this is all that is

necessary to keep the lamp burning brightly. Turn the lamp upside down, lay it on its side or let it fall, it will burn just the same. The Baldwin lamp gives a light of from 10 to 16 candle power, consuming not over eight ounces of calcium carbide in ten hours at an average cost of about two cents for the ten hours' run. To obtain a lamp of light weight a small water tank is made and extra bottoms to fit same supplied; the miner carries these extra bottoms filled with carbide in his pocket; on the charge being exhausted, it is taken out and the fresh one screwed into the lamp. The cover from the fresh charge being placed on the exhausted one, thus preventing all odor and any dirt in the pocket. On leaving the mine, the charges are emptied, and the receptacle refilled for the next day's use. Where the mines furnish the light, the general practice is, that some one can be instructed in the operation and maintenance of the lamps, and to keep them in repair and refill the charges. The miner on going into the mine is handed a lamp ready to burn, on the addition of a little water, which the miner puts in himself. Where the miners pay for their own light, they buy the carbide in bulk, keeping it in air-tight cans, and attend to the lamps themselves.

In presenting its catalog of Waugh drills the Denver Rock Drill and Machinery Company does not go into details relative to the merits of pneumatic hammer drills, as adapted for all classes of mining, in comparison with the old style piston drill. In the last few years rapid advancement has been made in the use of pneumatic hammer drills for mining. The hammer drill first came into prominence for use in stopes and raises where the cuttings would come out of the hole by gravity. The ability to put in a down hole and keep it free from cuttings, so that the drill bit would always have a fresh surface to cut against, for a time offered a problem difficult to solve. The Waugh sinking and drifting drill has solved this problem, and owing to its construction, a hole below the horizontal can be drilled with the same ease as a hole above the horizontal, and from which the cuttings will come out by gravity. The lightness of the hammer drill is its recommendation to the miner, and as it requires no "set up," a hole can be put in to take advantage of the seams and cracks existing in the rock to aid in breaking the greatest amount of material. The small amount of air consumed and the cheapness of maintenance, in connection with the large amount of work possible to be accomplished, must appeal to every mine manager who is endeavoring to break his ore at the lowest possible cost. Waugh drills are constructed out of tool steel, machinery steel and drop forgings. The workmanship is of the very best, and all parts are made to template and are readily interchangeable. The use of the Waugh stopping drill is sufficiently well understood to make an explanation of its uses superfluous. It is now possible, by the use of Waugh drills alone, to do any and all kinds of drilling in a mine where formerly hand work and piston drills were used. Not only are the drills intended for use in mines, but they can be used to equally good advantage for all classes of quarry work and general rock excavation. Waugh drills have, in the past, represented the standard of excellence, not only in perfection of construction, but in economy and ease of operation.

A new pump has just been put on the market to meet the demand of a moderate-cost machine of simple construction which will stand that wear and tear of rough usage and which at the same time can be operated without skilled attention. It is a strong plain pump designed particularly to overcome the objectionable features common to most pumps of this class, and results uniformly show that it has successfully accomplished this purpose. It is thoroughly adapted for rough mining service, for contractors' use, for boiler feeding or for any pressure work up to 200 lb. per sq. in. working water pressure. The valve gear is wholly

inclosed and there are no exposed working parts that can be tampered with, or become broken by accident. The pump can be put into any kind of unskilled hands, will stand all sorts of abuse and neglect and still keep on doing its work without giving trouble. Suction openings are cast on both sides of the pump cylinder and the discharge outlet can be faced in four different directions for convenience in making pipe connections. The steam and water cylinders can be turned end for end on the centerpiece connection so as to bring the handholes and pipe connections into the most accessible position when the pump is used in cramped situations. The water valves and valve seats are securely locked into place so that they cannot get adrift under any conditions, and at the same time, they can be quickly removed for inspection or renewal. Great care has been taken to make this pump thoroughly applicable to the varied conditions that continually confront users of this class of machinery and the favor with which it has been received, particularly by miners and contractors, tells its own convincing story. This line of pumps, denominated type "M" pumps, is built in a great variety of sizes, and prompt shipments can be made, which is a point very much to the purpose in modern manufacturing service. These pumps are built by the Blake & Knowles Steam Pump Works, of New York and Boston.

An Iron Deposit in the California Desert Region

The Ore Is a Soft or Semi-hard Hematite—A Replacement of Limestone near the Contact with Igneous Rock Accompanied by Vein Filling

BY CHARLES COLCOCK JONES*

The principal deposit described in this paper conforms exactly to the type referred to by Charles K. Leith in his report[†] on the iron ores of southern Utah. In the introduction to his contribution on this subject Mr. Leith says: "It early became apparent to me, as it had been to others, that the iron deposits of the West are prevaillingly of a distinct and uniform type—an irregular replacement of lime-

stone near the contact with igneous rocks, and uniform type, I have quoted from his paper because the deposit in question is so aptly described in the above paragraph. In the spring of 1906 while on a professional trip in the Providence mountains in the eastern part of San Bernardino county, Cal., between the Sante Fé railroad on the south and the Salt Lake road on the north, I first heard of and visited

paratively low pass running east and west near its south end. It rises from an elevation at the base of 2300 ft. to 6500 ft. on the highest peaks. The middle of the mountain is situated about 115 deg. 20 min. west longitude and 35 deg. north latitude. Kelso, the nearest desert town, lies about 4 miles west.

The longer axis of the mountain runs about north 20 deg. east, and this is also

FIG. 1. PANORAMIC VIEW OF PROVIDENCE MOUNTAIN, SAN BERNARDINO COUNTY, CALIFORNIA

FIG. 2. ORIGINAL BEDDING PLANES PRESERVED IN THE IRON ORE

FIG. 3. IRON ORE CLIFFS AT POINT E IN GENERAL VIEW

stone near the contact with igneous rocks, or a vein filling in both limestone and igneous rock—a type fundamentally different from that of the important producing districts east of the Mississippi river and probably of different origin."

While I do not entirely agree with Mr. Leith's generalization that the iron ores

this iron deposit, later becoming the owner of it by U. S. patent in 1908.

STRUCTURE OF THE MOUNTAIN MASS

Without taking into account the semi-detached outliers to the northeast and southwest, the Providence mountain proper is a single mountain mass about 25 miles long by 8 miles wide in its greatest dimensions. It is deeply cut by precipitous cañons on both the east and west sides, and is divided unequally by a com-

the general strike of the upturned sedimentary strata. Beginning at the base on the west side, at irregular intervals is seen the underlying granitic and gneissoid rocks; lying unconformably on this basement are about 500 ft. of quartzite with two thin shale beds near the top and a thin bed of conglomerate at the bottom; lying conformably above this are 4000 ft. of a series of generally heavy, bedded, blue limestones, with several beds of shale in the top 1000 ft., the whole forming a

*Consulting mining engineer, Los Angeles, Cal.

[†]Bulletin No. 338, U. S. Geological Survey, "Iron Ores of the Iron Springs District of Southern Utah."

series of almost perpendicular cliffs on the west side. The general strike of the beds is north 20 deg. east, with a dip of about 24 deg. to the southwest.

In my investigations no characteristic fossils have been found, but I am inclined to place the sedimentary formation as a whole in the lower Paleozoic series. The actual horizon, however, is of minor importance as related to the ore deposits, the veins or iron-ore deposits being primarily dependent on or connected with intrusive igneous rock in a sedimentary formation.

IGNEOUS INTRUSIONS

Nine miles southeast of Kelso occurs the low pass, already mentioned, at an elevation of 4200 ft., Kelso being 2100. This, known locally as Fooshay pass, follows generally the line of contact between the sedimentary series and an intrusive monzonite mass, and divides the mountain both physically and geologically—to the north of the pass is the sedimentary series and to the south the igneous intrusive mass.

Previous to the faulting which brought the monzonite in juxtaposition to the sedimentary series, but subsequent to or coincident with the upheaval which tilted the 5000 ft. or more of sedimentaries, there was a faulting of the already tilted series and an intrusion of highly acid or rhyolitic rocks in the form of a neck or plug near the middle of the mountain. It is roughly elliptical in shape, $1\frac{1}{4}$ miles long by $\frac{3}{4}$ mile wide, and so far as known entirely surrounded by sedimentaries preserving their general northeast strike and dip to the southeast. The relative positions as outlined above are clearly shown in the sketch map.

This central core or intrusive mass forms one of the highest and most rugged peaks of the whole mountain and erosion has exposed several contacts from the top to the bottom in the deep cañons between it and the limestones. The chief feature of interest about these contacts is the entire absence of metamorphism or evidence of any appreciable heat effect on the various beds of limestone. Only insignificant mineral bodies or slight replacements of any kind have been so far discovered along these contacts. Several narrow dikes of a feldspar porphyry have penetrated the limestone from this central core, the especial dike having any collateral bearing on the iron deposits being the one indicated in the general view from Y to Z.

ADJACENT ROCKS

The panoramic view, Fig. 1, shows the monzonite rocks in the foreground and the line of contact with the sedimentaries. The chief iron deposit occurs as shown at A to E at the west corner of an oblong mass of marbleized limestone. To the northeast on the line Z Y, this block is bounded by a vertical dike of feldspar porphyry,

about 75 ft. wide, which is an offshoot from the main porphyry core spoken of above and shown at the top and upper right hand corner of photograph. The monzonite contact bounds the south side of the block and curves eastwardly around the west end of the iron body for a distance of 200 ft. and probably projects at depth to a considerable distance further under the line to the northeast, forming the other boundary of the block.

The principal part of this block forms a sharp ridge about 3000 ft. long by 1000 wide and 500 ft. high, and shows almost complete loss of original bedding planes, a metamorphism of the limestones through

west-southeast direction with a greatest width of 290 ft. and an elevation above the cross gulch of 260 ft. The northwest portion of this body is in direct contact with the monzonite on the south, the west and for some distance on the north. The southeast portion of the ore-body leaves the contact and projects into the limestone and by erosion the harder iron ore has been left standing above the surrounding metamorphosed limestone to a height of from 10 to 50 ft. These features are shown in Figs. 5 and 6.

EFFECT OF THE MONZONITE INTRUSION

The general dip of the limestone beds

FIG. 4. SKETCH MAP SHOWING LOCATION AND GENERAL GEOLOGY

heat and pressure to marble, and a shearing with a deposition of veinlets of iron in the cracks and a large distribution of shot iron throughout the marbleized lime. This latter condition, especially at and near the contact, shows all the phases from innumerable mere pin points of bright hematite to reticulated veins of the same in the metamorphosed limestone and on up to complete replacement of the limestone by iron ore.

The chief deposit of iron ore occurs at the point A where erosion has exposed the body for a length of 775 ft. in a north-

in the Providence mountain to the southeast has brought what were among the top beds of the series at the west side into contact with the monzonite at the iron deposit and it appears to me as the simplest explanation that the pressure exerted by the intrusion of the monzonite in the special area under consideration, A Y Z, opposed by the rigidity of the dike Y Z and the mountain mass beyond to the northeast, resulted in a flat anticlinal beginning at the point A and including the small ridge.

This is plainly shown in Fig 5, where

at the contact the old bedding planes of limestone are seen dipping to the southwest, cut at a steep angle by the monzonite, and (on a larger scale) in Fig. 2, just north of this showing the individual beds of iron, representing clearly the replaced beds of limestone, dipping slightly to the northeast. This anticlinal zone of compression, complicated by shearing stresses the results of which are indicated in short but effective north-south faulting (both being the effect of the intrusion of a large mass of igneous

tine and actinolite some distance north of the contact in limestone. There is an absence of garnetization or epidotization in any of the limestone beds, which is rather noticeable in view of the somewhat common occurrence of these products of metamorphism under similar conditions in this immediate region.

At a short distance from the contact considerable epidote has been developed in the monzonite following the action, which jointed it and which was probably con-

filling the pores. It belongs to a most desirable class of soft or semi-hard hematite ores of which there are unfortunately but a few deposits so far discovered in California. The analyses given herewith were made through the courtesy of E. N. Breitung, at the laboratory of the Breitung Hematite Mining Company, Negaunee, Mich.

IRON ORE ASSAYS.

	No. 1	No. 2	No. 3	No. 4
Iron	66.40	65.70	64.00	63.40
Phosphorus	0.046	0.088	0.045	0.052
Silica	1.02	2.67	4.00	4.47
Manganese	0.295	0.278	0.254	0.287
Alumina	0.213	0.187	0.468	1.403
Magnesia	0.226	0.179	0.204	0.197
Lime	0.421	0.347	0.562	0.443
Sulphur	0.042	0.076	0.070	0.049
Volatile	1.75	1.50	2.01	2.16
	70.413	71.025	71.613	72.463

No. 1 is a bulk sample from underground. Nos. 2, 3 and 4 are samples from the surface at different points. These four show the highest phosphorus obtained from a number of samples and it ranges from the figures above down to 0.020 per cent., the average of 10 samples is iron 64.82 per cent., phosphorus 0.0434 per cent.

MAGNETIC AND ECONOMIC FEATURES

As a matter of interest, when considering the magnetic qualities of the ore, calculations were made based on the above complete analyses in which by satisfying

FIG. 5. VULCAN IRON DEPOSIT—LOOKING NORTHWEST

rock into favorable sedimentary strata) afforded excellent conditions for replacement by mineral bearing solutions from below.

The contact generally for two miles shows small iron contact veins or deposits or metamorphosed limestone highly charged with iron particles, but with the exception of the large deposit and the bodies at *W*, they are not of any appreciable extent at the surface. The lenses or bodies at *W* differ from the chief ore deposit at *A* in being strictly contact deposits, as far as the surface indicates, running in size from several feet in thickness to 25 to 50 ft., accompanied by thicknesses up to 50 ft. of marbleized lime containing at least 50 per cent. iron in reticulated vein form.

The only copper indications so far observed are found to the east of point *W*, occurring as a small proportion of chalcocopyrite at one place in the crystalline limestone immediately adjacent to the monzonite contact. There are no present features about the main ore body to indicate the presence of copper nor has it any similarity to a gossan capping.

PRODUCTS OF METAMORPHISM

Beyond the change of limestone to marble or highly crystalline limestone, the products of metamorphism so far as observed are few—a slight kaolinization of the monzonite immediately at the contact, and a few thin beds or patches of serpen-

FIG. 6. VULCAN IRON DEPOSIT—LOOKING SOUTHEAST

nected with the intrusion of numerous diorite dikes or bosses, beginning a short distance south of the contact but nowhere seen as accompanying or cutting the actual contact.

THE IRON ORE

The iron ore is a soft red hematite with considerable magnetism; on the surface it weathers hard and appears black, but upon penetrating it a few feet it is porous, shatters easily in mining and in the tunnels and on the dumps has the appearance of a limonite on account of the ochreous dust

the iron as a hematite (Fe_2O_3) and not accounting for any other small amounts of oxygen the results ranged from 98.86 to 99.61 per cent. for the sum of complete analyses, and satisfying the same as magnetite (Fe_3O_4) the results were from 95.71 to 96.63 per cent., so that from an analytical standpoint the ores are unquestionably hematite. The matter of the magnetism or magnetic quality of iron ores is an interesting one and I should like to see published the observations of others on this subject.

It is conservatively estimated that there

are 2,000,000 tons of ore available above a track level on this property capable of being quarried and loaded at a minimum cost and as the iron beds are shown in place going down below this level and all conditions would point to a continuity to considerable depth, there is every reason to believe that the actual tonnage will be several times the above amount. Unlike a number of other desert deposits, this property is favorably situated in being but nine miles from a railroad with a down grade, and in reasonable distance from the sea coast.

OTHER NEIGHBORING DEPOSITS

Without being able to give a complete description it is interesting to know that four miles east of Kelso at the point *B* on the sketch map, and about three miles north of the orebody already described, occurs another iron deposit of a different class. Here the sedimentary formation has been faulted near the base and an igneous rock, similar to the monzonite occurring in Fooshay pass, but complicated with a more basic rock, has cut the quartzite at a high angle to the west of it, and parallel with its strike, north 20 deg. east, and along this contact a vein 40 to 50 ft. wide of hard specular iron ore of a high quality has been developed for several hundred feet. This occurrence is below the limestone and seemingly not connected with it in any way.

North of Kelso three miles, at the point *D* occurs a vein of high-grade, hard, red hematite, four to 10 ft. thick, standing vertically and traceable for 2000 ft. So far as the surface shows, it represents a replaced limestone bed just above the quartzite and is accompanied by unaltered parallel limestone beds. The quartzite is correlated with that at the base of the formation in the Providence mountains. The ore in this instance, while not seen in direct contact with intrusive igneous rocks, is undoubtedly one of the results of the injection of diorites into the sedimentaries which are close by.

The subject of western iron ores is likely to become of importance in the near future, not only by reason of the exhaustion of high-grade ore in other sections of the country, but on account of the necessity for filling the growing demands of the Pacific coast more cheaply than at present. China today is shipping cargoes of pig iron to California, a fact hardly appreciated. I think, by ironmasters advocating a reduction in tariff on iron and steel at the present time. With its known large resources, cheap labor and modern iron and steel plants, China is a factor not to be overlooked. The hope of the Western coast lies in cheap fuel on Puget sound or the utilization of California oil in smelting iron ores.

Novel Hand-Crushing Device

By HERBERT L. JENE*

Having found the ordinary bucking plate quite unsuitable for crushing down samples of coarse ore on account of the fact that much of the material is apt to fly away in the process of bucking, I devised the apparatus shown in the accompanying illustration. It consists of a base or pedestal, a galvanized-iron tray and an iron pipe which, fitting over the base, forms the mortar. The base is a one-piece iron casting the bottom of which is 12 in. square and 2 in. thick, with a top projection 3 in. high by 6 in. diameter.

In using the apparatus the tray and pipe are placed in position, and then the coarse ore is thrown in and broken down with the stamper. When sufficiently fine, the stamper and pipe are removed, and the ore brushed upon the tray. The pipe is then replaced, and the operation repeated until the sample is completed. The pipe is then removed, the ore on the mortar base is brushed off and the tray carefully removed. The sample ready for quartering and final grinding on a bucking plate is poured into a bag through the small lip *c*. This apparatus is particularly suitable for kerosene shale or any material which is apt to fly during crushing. The pipe can be made longer

DEVICE FOR CRUSHING COARSE SAMPLES OF ORE

Over this fits closely a galvanized iron tray *d e* 20 in. square with the edges turned up 2 in. leaving a lip *c* 4 in. wide, in one corner. In the center of the tray is a hole $6\frac{1}{8}$ in. diameter so that it can fit over the top of the pedestal. A piece of 3/16-in. iron piping $6\frac{1}{8}$ in. diameter and 2 ft. long fits over the top of the pedestal and tray. The iron pestle or stamper is 3 ft. 6 in. long with a shoe 4 in. diameter by 1 in. thick; the stem of the pestle is $1\frac{1}{2}$ in. in diameter at the bottom and gradually tapers to 1 in. at the top.

or shorter according to the nature of the material being crushed.

*Mine examiner and analyst, care Commonwealth Oil Corporation, Sydney, Australia.

In the annual report of the Transvaal State mining engineer, U. P. Swinburne reports that there are several large deposits of iron ore in the Barberton, Lydenburg, Middelburg and Pretoria districts, but most of them carry so high a percentage of titanium, that they are not available commercially at present. Some experiments are being made with limonite and hematite ores comparatively free from titanium, which are found near Pretoria. No iron is now made in the Transvaal.

Kimberlite Rock and the Origin of Diamonds

Serpentinization Responsible for Many Peculiarities of the Pipes; Kimberlite a Serpentinized Pyroxenite. Broken Diamonds; Exploding at Surface

B Y F. W. V O I T *

Since I read my papers on these subjects I have had occasion to study microscopically a good many rocks from pipes and dikes, and the discussions of these papers have developed some new ideas which I should like to make known.

Kimberlite has always been described as a serpentinous breccia, the serpentinized portion of the rock being altered olivine; generally the term "serpentinized peridotite breccia" has been accepted. The material filling the pipes was said to have been formed at great depths and brought to the surface by volcanic action. The rock itself, its occurrence and the way it came to the earth's surface have been described as being unique and as having an extraordinary and unusual genesis.

I must admit that the decomposition of the kimberlite has gone so far that it will be extremely difficult to come to a conclusion as to its true character. My investigations convince me that up to the present time justice has not been done the kimberlite rock, and that some extraordinary characteristics, which certainly do exist, induced people to attribute to it an unusual genesis.

The slides which I examined are from pipe rock near Kimberley, the Roberts Victor, Voorspoed, Regina, Lovedale, Monastery, Premier, Zonderwater, etc., and dike rocks from Kimberley, Paardeberg, Prieska, Vulcan, Smaldeal, etc.

It is characteristic that while the pipe and dike rock of one district resemble each other very closely they can easily be distinguished from similar rocks of other districts, so that we have a Kimberley type, Roberts Victor type, Premier type, etc. From the description of the slides some of the more important of which are given below, it will be seen that I laid stress only on three points: First, on the imputed brecciated character, due to the movement of a molten mass in an open crater containing minerals of a deep-seated origin; second, to the structure of the rock; third, to the chief constituents building up the rock, whose presence gives it its name.

GENERAL CLASSIFICATIONS

With regard to the term peridotite, with which generally the kimberlite is classed, I wish to point out that Harger first drew attention to the fact that in many cases pyroxene was undoubtedly prevalent in

the rock. In the numerous slides examined, I did not find one in which the olivine occurred in such quantities that it would be justifiable to call the rock a peridotite. With reference to the use of the term breccia, I have previously pointed out that the kimberlite might be called a breccia only with regard to the sometimes angular, sometimes rounded inclosures of foreign rock fragments, though for my part I prefer the term agglomerate.

There are undoubtedly strong evidences of pressure in the rock in the shape of broken and bent minerals. In large specimens as shown by Mr. Harger, I would attribute this phenomenon in greater part to the secondary protrusions of a magma. The broken character, however, of phenocrysts of mica and pyroxene is, under the microscope, clearly due to serpentinization. The more serpentinized the rock is the more we find the phenocrysts broken and bent.

PIPE ROCK MORE PORPHYRITIC

With regard to the structure of the rock, we have to do with a rock very similar to "Ganggestein," that is, a rock standing between a plutonic and an effusive rock; we have a magma crystallized out *in situ* and under pressure. There are always two distinct generations, and the rock is more porphyritic in pipes and more basaltic in dikes. All the minerals have apparently crystallized out *in situ*, though occasionally crystallization during the ascension of the magma may have taken place since under the microscope we sometimes find corroded crystals.

The great variety of the accessory minerals we have to a certain extent be due to the incorporation of rock fragments of different chemical compositions in a magma of great resorbing capacity. In fact I believe that the broken fragments of deep seated rocks have been dissolved to a certain extent by the ascending magma and in this way attained their rounded forms.

DESCRIPTION OF ROCKS

1. *Kimberley Mine*—(2400 ft.) Large phenocrysts of pyroxene (diopside ?) and some mica in a finely crystalline mesostasis of serpentine, probably also pyroxene; typical porphyritic structure. Pyroxenite porphyry.

4. *Robert Victor*—Pyroxene phenocrysts; much evidence of pressure, secondary green mica mesostasis finely crystalline, pyroxene (?) Typical porphyritic structure. Pyroxene porphyry.

5. *Roberts Victor*—Fissures. Augite phenocrysts (a few small olivines) in

augitic mesostasis; structure more basaltic.

7. *Prieska Diamonds*—Fissure. Cryptocrystalline rock, all augitic; a few augite crystals, structure basaltic.

9. *Lovedale*—This mine contains plentiful segregations of a (macroscopically) coarsely crystalline diopside rock containing many garnets (eclogite) in a finely crystalline diopside blue ground of very similar character. Under the microscope the segregations are a coarsely crystalline mixture of diopside and some enstatite, both strongly hydrated; garnets showing kelyphisation; this rock gives to a certain extent the impression of a holocrystalline structure. The zone into which the segregation gradually passes, is cryptocrystalline and shows besides serpentine, secondary sericitic mica.

12. *Premier Mine*—Bore core 500 ft. Pyroxene porphyry, containing small olivines.

16. *Fissure from Klein Zonderhout*—(Twenty miles south of Premier). (a) Augite crystals, fibrous by secondary products in augitic ground mass; basaltic structure. (b) Phenocrysts of augite (partly altered into mica) and vaalite, feldspar (?) including a mica; more porphyritic structure.

I must note that a few times in examining the slides I got a suspicion that feldspar might be present. The decomposition, however, has gone so far that I doubt whether that point will ever be settled. I found in No. 16b, a mineral which certainly showed faint traces of polysynthetic twinning. There are orderly arranged inclusions of secondary, highly hydrated nature which points to schillerization, though nothing definite can be stated with regard to this point. Characteristic of all these slides was the absence of any glass which one would expect in a rock cooled down in an open crater.

The difference in the structure of the pipe and the dike rocks is generally very marked, though apparently connecting links between both may exist (No. 16b). The difference of both structures may be due to the slow cooling down of the pipe rock in a large basin and the quicker cooling down of the dike rock between the narrow walls of the fissure. However, we then would expect toward the walls of the pipe a rather basaltic structure similar to dike rock which is not the case.

Nearly always a few feet from the walls the pipe rock is simply found to be "hardbank," which is in no way except disintegration different from the soft blue rock. If microscopic examinations do not give

*Consulting geologist, Schloss Str. 8, Steglitz, Berlin, Germany.

NOTE—Abstract of a paper read before the Geological Society of South Africa.

us a final result with regard to the relation of dikes to pipe rock, field evidence shows a marked difference between the two rocks. We must abandon the term peridotite, as the rock is much more likely to be a porphyritic pyroxenite.

DIAMONDS IN DIABASIC ROCKS

I am inclined to look upon kimberlite as the last evidence of a series of volcanic activities (in the larger sense of the word) during and after the sedimentation of the Karow formation, beginning with unusually acid quartz diabases in the lower beds of the Karow. In the middle and upper beds these diabase sheets take a more and more normal character (augite-feldspar) until finally in the extrusion of the kimberlite the ultra-basic magma was extruded from the zone of reconstruction. Chemically we have a transition of diabases into kimberlites, and field evidence is apparently strongly in favor of this assumption. Everybody who has worked on the veldt has had the experience of being uncertain whether he has to classify certain rocks as diabase or as kimberlite.

If we have on the one side a kimberlite free of all the accessory minerals, and being simply a serpentinized pyroxenite, we occasionally find on the other hand in diabases large ilmenite segregations and numerous garnets. Rocks of diabasic character and belonging to the older horizons may even contain diamonds and many of the accessory minerals typical of kimberlite. This latter point may turn out to be of great interest, as we might then expect to find diamonds in diabases and similar rocks here in Africa, as they were found in hornblende diabases in other countries,¹ and this possibility throws a new light on the occurrence of diamonds on many of the so-called alluvial diggings.

ALLUVIAL AND OTHER DEPOSITS

It is extraordinary how widely spread we find the diamonds in South Africa; there are diamond fields far from the river on the high plateau where the old river never flowed, as for instance, the Vaal river, Pniel estate, etc. We find diamonds 25 miles north of Bloemhof spread over a wide area where no alluvial gravel exists; again, we find them near Christiana upon the heights where also are no traces of old river gravel. Here the diamonds are simply found in the decomposition products of the country rock, a very green, hard, sometimes amygdaloidal rock of diabasic character, which as feldspar is inferior in quantity to pyroxene, would rather deserve the name of pyroxenite.

Generally the gravel of the so-called alluvial diamondfield is absolutely different from the gravel of the modern rivers, and it is most likely that the diamonds have weathered out there *in situ* from

diamondiferous diabasic rocks of different ages. We may assume, for instance, that the diamonds on the Harrisdale ground came from a now denuded kimberlite sheet, as we know by borehole results that extensive sheets of kimberlite, or a rock very similar to it, still exist on the ground.

WEATHERED PRODUCTS OF DIABASE DIKES

Some of these diamonds may weather out from diabase dikes and there is a strong suspicion that the diamonds on the Pniel and Vaal river estates have weathered out from the amygdaloidal diabase underlying the Dwyka conglomerate and are still doing so. The many blue, black, yellow, brown-banded chert jaspers and ferruginous cherts, known as bantams, looking as if they were waterworn, have weathered out from the Dwyka conglomerate, and were concentrated *in situ*.

There is a marked difference in the gravel of the present river beds of the true alluvial deposits, and the gravel of those alluvial deposits; furthermore, hard as the diamond is, it would show a good deal of attrition if it had traveled a long way, but in most cases these diamonds show sharp edges just as stones from the pipes. The contention has also been that the diamonds in these gravel deposits may come from a yet undiscovered pipe in the neighborhood. Following up this theory we may expect occasionally to find diamonds in pyroxene rocks of any geological horizon and the diamonds in the conglomerates of the Witwatersrand reef beds of the Klerksdorp district, for instance, may have been derived from those diabasic rocks which are members of the Swaziland beds or fundamental gneiss formation.

ECLOGITE SEGREGATIONS

With regard to the much-disputed character of the eclogite nodules I should like to make the following remarks. From all sides, especially from Mr. Bonney and Mr. Harger, the rounded faces of all the "eclogites and similar boulders" have been taken as the stumbling block to the segregation theory. Mr. Bonney says that Mr. Corstorphine and myself tacitly repudiate the rounding of these eclogite and similar boulders by a sort of "cup-and-ball action" in a volcanic pipe.

I consider this term "cup-and-ball action" extremely ill chosen, as I think that nothing of that sort happened. I rather think the rounded nature of foreign rock fragments is due simply to the dissolving capacity of the kimberlite magma which has eaten away the corners and left a more rounded fragment. I always maintained that often a characteristic of segregations of a magma is their rounded shape, and we must not forget that contact metamorphism on foreign rock fragments included in a magma can also be found on segregations.

SPECIMENS FROM LOVEDALE MINE

From many eclogite segregations which I saw, I brought before this society some specimens from the Lovedale mine with the including blue ground, and it is accepted that these cannot be anything else than segregations. The chemical composition of the nodule and its matrix is absolutely the same; in both cases a diopsidic rock with more or less garnet, still we have that smooth and absolutely rounded surface which Mr. Bonney perhaps would call waterworn.

Elipsoidal or perfectly round balls of these nodules—to which the term "cup-and-ball action" might be very well applied—exist in the mine and where they are still imbedded in the finely grained blue ground, their sharp contours can be seen; the contact of nodules and matrix is extraordinarily abrupt and well marked. I will not deny that occasionally an eclogite may be an exotic rock and may have been brought up by the ascending magma. Certain banded eclogites with pink garnets are probably exotic rock fragments but the greater number of all the eclogites and similar rocks are certainly segregations.

SERPENTINIZATION AND ITS EFFECTS

Before concluding this paper I wish to make some remarks about the alteration of the kimberlite. This point has been recorded by du Toit. I think that up to the present too little attention has been given to that point. Du Toit calculates that the increase in bulk of the material in passing into the stage which we know as blue ground would be something like 13½ per cent.; in fact it would probably be higher as the original mineral which built up the rock is in most cases diopsidic.

Covered as the pipes were, the pipe material during its serpentinization could not extend anywhere and it is clear that the breaking effect due to an increase in volume, must have been considerable. That effect of pressure we can observe under the microscope beautifully, and we can safely say the more decomposed the kimberlite is, the more its phenocrysts are bent and broken. I think that this expansive force which did not find an outlet must have also had an effect on the large crystals of the accessory minerals which were broken, and here we may find an explanation for the broken diamonds.

THE CULLINAN AND BROKEN DIAMONDS

Of these broken diamonds Gardner Williams says: "The frequent occurrence of broken diamonds imbedded in hard kimberlite is a conclusive proof that the diamonds do not occur in their original place of crystallization." I personally think that these so-called splinters are nothing but incomplete forms of crystallization but I should not like to give a definite opinion about it.

Certainly I am not so sure about the Cullinan being a broken diamond. It may

¹"The Origin and Occurrence of the Diamond," by Prof. T. W. E. David, THE ENGINEERING AND MINING JOURNAL, APR. 24, 1907.

have laid against a boulder and the growing of the crystal could only take place toward certain directions on a certain number of faces. However, I saw indubitable splinters myself and I think it is possible that some diamonds may have been broken in the blue ground itself by secondary magmatic and gaseous extrusions during and after the formation of the pipe, or by the pressure during serpentinization. We know that the diamond is very brittle and cracks very easily if only a slight pressure or blow is exercised.

EXPLODING OF DIAMONDS

Whether it is true or not that diamonds explode when brought to the surface, I do not know. Croakes and Gardner Williams state it, and the latter says that this cracking is more due to the result of heat or drying than to the tension of inward pressure. If this exploding of diamonds really happens, then, I think, we may have to do with a displacement of the molecular arrangement due to a change in temperature very similar to the leucite phenomenon.

A similar displacement of the molecular arrangement in the diamond may take place during the cooling of the magma and may be responsible for the breaking of diamonds.

All the conditions which may make a diamond explode on the surface may have been present in the interior of the pipe during the various phases of temperature: Cooling down of the magma; rise of temperature during serpentinization.

If broken diamonds exist in such quantities as maintained by certain people, we have more than one sound explanation for this phenomenon and we need not look for such a far-fetched idea that diamonds formed at an unknown depth were separated from their original source and brought into the pipe by volcanic action through which they were more or less broken.

A Deep Diamond Drill Hole

At Bisbee, Ariz., in late years, there has been a great deal of prospecting with the diamond drill. Boring has recently been done on the property of the Warren Realty and Development Company, and on that of the American Development Company. The former has finished a hole 3200 ft. in depth, which is claimed to be the deepest diamond-drill hole yet bored in the United States. This hole was put down vertically on the flat ground about half way between Bisbee and Osburn Junction, a few miles southeast of Bisbee. It required one year and 10 days to complete the hole, working one nine-hour shift per day. About two weeks' work were lost in repairs not chargeable to the drilling. The drill used was a Sullivan, Class "C," single-cylinder,

hydraulic-feed drill, having a rated capacity of 1500 ft., and removing a $1\frac{1}{8}$ -in. core. When work was begun it was not the intention to go to such a great depth, or a larger drill would have been installed. The "C" machine performed the work satisfactorily, however, the only trouble caused by the severe overload being the breakage of a gear stand, which was easily remedied.

The drilling of this deep hole involved some interesting features. Diamond drills have received more or less criticism from time to time on account of the deviation of the hole from its true course under certain conditions. Some writers have gone so far as to say that drill holes will deviate in any case, whether conditions outside of the drill are favorable for this action or not. This particular bore hole was perfectly true from top to bottom. At its completion it was tested several times with a clinometer, consisting of a closed glass tube about half full of hydrofluoric acid. This instrument was placed in a metal tube, carefully sealed to exclude water, and lowered in the core barrel to the foot of the hole. After waiting a half hour or longer, it was removed. The acid in each case etched a horizontal circle on the glass, showing that the tube had maintained a vertical position.

The time required to hoist or lower the rods at the final depth was $2\frac{1}{4}$ hours. The rods were pulled 20 ft. at a time by means of a single sheave, and lowered with the engine. In the course of the year's work five $\frac{5}{8}$ -in. first-quality steel ropes were worn out. A timber derrick 36 ft. high served to pull the rods. For the first 580 ft. the drill bits had to be reset about every 8 ft. Below that depth more favorable ground was reached, so that a size "A" bit ran for 30 ft. on an average. Eight carbons were used, being set with $1/64$ -in. clearance. Care in setting the bits evenly and with a small clearance was probably responsible for the success of this hole. It has often been noted that excessive clearance results in more or less serious deviation. In fact, in the case of a number of deep bore holes in South Africa, in which serious deviation from a true direction occurred, it was observed in each instance that the diamonds had been habitually set with an excessive clearance.

The mining company, through its drilling superintendent, Louis Buese, of Republic, Mich., gives the following information regarding the progress of the work: Standpipe was driven through 38 ft. of surface, and the casing secured by drilling it 4 ft. into the rock. Soft ground was encountered at several places, down to 580 ft. Instead of reaming out the hole and casing it, to overcome the trouble, the cementing method was employed. After drilling as far as possible in the soft ground, cement was pumped down through the rods, the rods pulled, and the cement

left to harden until the next day. This cementing kept the hole tight, and secured return water as far as 580 ft. In the lower part of the hole the water gradually decreased and at last failed to return at all. As the core was good, however, no effort was made to get the water back. Power was supplied by a 20-h.p. upright boiler.

Most of the very deep holes bored in recent years have been in the Transvaal. At least three have gone to depths of more than one mile, viz., 5560, 5582, and 6340 ft., respectively. For this heavy drilling the Sullivan Class "P" (4000-ft) or Class "K" (5000-ft.) drills were used. The rods were hoisted in 50-ft. sections, with double sheaves. A mile of rods required about 8 to 10 hours constant labor for its removal from the hole.

New Proposals for Zinc Extraction

Woldemar Hommel and Henry L. Sulman, London, Eng. (Brit. pat. No. 23,901 of 1907) describe an improved process based on British patent No. 21,672 of 1906 granted Henry L. Sulman. The ore is generally roasted, and if there is not sufficient sulphur present, iron pyrites or an ore rich in sulphur is added to supply the necessary quantity for sulphurous acid, while the iron serves as a flux for the subsequent smelting of the lead. The ore is then placed in a furnace, the zinc volatilized and collected in a series of fluxes or condensing chambers. It is then treated with a solution of sulphurous acid to obtain a solution of bisulphite of zinc, from which monosulphite is precipitated, and calcined to produce zinc oxide.

Antoine H. Imbert, Grand Montrouge, Seine, France (Brit. pat. No. 13,492 of 1908), describes an invention that follows his British patents, 10,303 of 1906, and 12,591 and 12,592 of 1907, which claimed that in the reduction of blende and analogous ores and also certain oxide ores, peroxide of iron (Fe_2O_3) might be used with a basic oxide or a metallic sulphide to form the solvent. The present invention is based on the discovery that peroxide of iron itself may, under certain conditions, be employed as a solvent.

The blende or ore is heated in a furnace with the peroxide of iron in the proportion of two equivalents of the former to one of the latter. The reacting metal, i.e., the iron, may be used in a solid form, but is preferably heated to a molten condition in a furnace. Baths from the furnaces are brought together in a hermetically closed chamber protected from the air, the iron being added in a sufficient quantity to balance automatically the zinc of the ore. The zinc is released as a vapor and is led into a condensation chamber, while the liquid residuum is drawn from the reaction chamber.

The Three Producing Gold Mines of France

Associated with Antimony and with Arsenic the By-products Are of Importance. Brief Outline of Reduction Plants for These Refractory Ores

B Y E . W A L C H *

There are at present three producing gold mines in France. To those who have not made a study of the French mineral production, it will be of interest to note the geographical distribution of these three mines. One is in almost the exact center of the Republic in the Department of Creuse. The other two producing mines are situated respectively in the Departments of Mayenne and Maine et Loire, in the northwestern part of France, about 150 miles southwest of Paris. The latter two have been completely equipped for some years, and the Société Anonyme des Mines d'Or du Chatelet, in Creuse, is erecting an entirely new plant which is expected to be in running order during the early months of this year.

The oldest of these three mines at Le Genest (Mayenne) is worked by the

bodies are almost vertical, and are worked from three shafts to a present depth of 200 m. The ore contains gold as an auriferous quartz, and antimony chiefly as stibnite. Both metals are recovered.

METALLURGICAL TREATMENT

The run-of-mine ore is first picked and separated into two general classes, antimony ores and auriferous quartz. The former is treated in a concentrating plant of a maximum capacity of 300 tons daily. This plant consists of crushers, a Cox screening machine and 3-compartment Harz jigs. According to their percentage in antimony, the products of this mill are either smelted to regulus, or roasted to obtain the oxide of antimony for which there is a good market. A new smelting plant has just been started to recover the

employed in the mine and reduction works. Although the price of antimony dropped considerably during 1907, from about 25c. per lb. to 8c., the company sold 2,629,061 fr. worth of antimony and antimony oxide. From gold bullion and concentrates they realized 1,050,379 fr., when 10 stamps only were at work. The company declared for 1907 a dividend of 35 per cent.

The next gold mine opened in France was la Bellière, controlled by the Société des Mines de la Bellière, which was also floated by Baron Léonino and Mr. Strap, with a capital of 4,000,000 fr. in 1905, when the mine was granted to them by the French government. This mine is situated at St. Pierre-Montlimart (Maine et Loire), south of the Loire river and about equidistant between Nantes and Angers. This property is supposed to

ST. JEAN SHAFT—MINES DE LA BELLIERE

GENERAL VIEW OF REDUCTION WORKS

Société Nouvelle des Mines de la Lucette, capitalized at 3,150,000 fr. This mine was "granted" in 1889 as an antimony mine. The old company, after a futile attempt to work the mine, sold its rights to the present company, which was floated by Baron Léonino, a relative of the Baron de Rothschild, assisted by Jules Strap, a mining engineer who had examined the property and confirmed the existence of gold in payable quantities in the ore. These gentlemen later disposed of their interest in order to bring all their efforts to the opening of another gold property, the Mines de la Bellière.

The Lucette mine is now under the management of Mr. Riber, at the head office, and Mr. Normandin, at the mine. It is one of the largest antimony mines in the world. Its production in 1906 was 7300 metric tons, or nearly one-quarter of the world's production, and about one-half of the production of France. The ore

gold contained in the antimony. This plant is capable of producing monthly 200 metric tons of oxide of antimony and 150 tons of regulus.

The gold quartz is further separated by hand into rich and poor quartz, the former being at present sold to smelters, and the latter being treated in the 20-stamp mill. The stamps, 10 of which were recently started, are of 1000-lb. weight, and it has been found that about 50 per cent. of the gold is free-milling. The pulp from the stamp batteries is concentrated on No. 5 Wilfley tables, of which there are 12, giving two classes of concentrate, one with 55 grams and the other with 500 grams of gold per metric ton. These concentrates are sold.

The company is installing a 5-ft. Elmore vacuum concentrator for the purpose of experimenting upon various classes of product, especially on the old slimes.

Electric power is produced by the company with an 800-kw. machine and is used for all purposes. About 600 workmen are

have been worked by the Romans at an early date to a depth of about 20 to 30 m. when water was met and work abandoned.

The ore consists of quartz and mispickel with some pyrite, chalcopyrite and galena. The mispickel contains the largest part of the gold and yields from 35 to 40 grams of gold per metric ton, while the ore after the hand-sorting carries only from 15 to 16 grams per ton. The gold content increases with the percentage of galena, which also carries a fair amount of silver so that the bullion contains from 15 to 20 per cent. silver. The orebody varies in thickness from 12 to 10 m., and is surrounded by ancient shales, and has been identified for a length of over 1600 meters.

The ore is treated in a 40-stamp mill, with concentrating, roasting and cyanide adjuncts. The ore as it comes from the shaft is crushed in a 20x10 Blake crusher, which delivers it to a Robins picking belt, which conveys the ore to two 11x15 Dodge

*25 Rue LaMotte, Paris, France

crushers placed over the bins of the stamp mill. The stamps weigh 1050 lb., and the mortars are fitted with 30-mesh wire screens. Copper amalgamating plates are used and inside amalgamation is also practiced. According to the varying character of the ore, from 35 to 48 per cent. of the gold is amalgamated. Amalgamation with the Bellière ore is difficult, as films of oxysulphides are soon formed on the surface of the quicksilver. Careful attention by the millman is required, and each five stamps are stopped every four or five hours to clean up the copper plates. The quartz itself is very hard, and the capacity per stamp is only about 3.4 metric tons per 24 hours.

After passing through the stamp mill the pulp is sized in spitzkasten and concentrated on Wilfley tables. The concentrates which are very high in arsenic and gold are then roasted. In the roasting department the company recovers As_2O_3 and SO_2 . The sulphurous anhydride is used to make hyposulphite of lime. The roasted concentrate as well as the tails from the Wilfley tables, which carry a few grams of gold, are cyanided.

A MODERN CYANIDE PLANT

The cyanide plant at la Bellière is fitted with many modern appliances, such as excavators, movable distributors and an extensive system of Robins belt conveyers for feeding and emptying the leaching vats and taking the tails to the waste heap. Slimes are agitated by air and the gold is precipitated in the usual way by zinc shavings. A new 30-stamp mill with 1500-lb. stamps is under construction. It is expected that it will enable the company to double the capacity of the plant which mills at present about 130 tons daily. The concentrating and cyanide plants will, of course, be increased in proportion.

The results in 1907 were satisfactory, although the cyanide plant did not work regularly, being mainly used for experimenting and determining the best way of dealing with the refractory ores. As a very small proportion of the ores milled passed through the cyanide plant, the particulars published by the company are not of great interest. The only interesting feature is that on the portion of the ore which was fully treated 89 per cent. of the gold was saved. At the stamp mill 43,415 metric tons of ore were milled in 1907, producing 1052 kg. of amalgam (about 805 kg. were recovered on the copper plates and 247 in the mortars), containing 284 kg. of fine gold and 42 kg. of fine silver. The average content of the ore, calculated from about 1400 assays of samples taken at the feeders, was 14.5 grams (about 0.5 oz.) per ton, the recovery in the stamp mill being about 45 per cent. The Wilfley tables produced 1260 tons of concentrate and 7185 tons of middlings and sands. The sands and slimes from the tables will be fully treated in the new cyanide plant.

Additional gold was recovered in the experiments in the cyanide plant, bringing the total gold saved by the company in 1907 up to 347,610 grams having a value of 1,193,796 fr. They sold in addition 79,566 kg. of oxide of arsenic bringing 40,920 fr. In the near future it is expected that the arsenic plant will produce from 300 to 400 metric tons per year. The whole plant is electrically driven from a power station of 750 h.p., and an average of 450 workmen are employed in the mine and the dressing plant.

THE CHATELET MINE

The third producing gold mine is controlled by the Société Anonyme des Mines d'Or du Chatelet (Creuse), with a capital of 7,500,000 fr. The mine which was only recently opened is situated at Chambon-sur-Vouge in the Department of Creuse in a very hilly region in the center of France. The mine was granted by the

is now almost completed, and will be started during the first half of 1909. In the dry crushing plant are dryers, Blake crushers and ball mills. Following the crusher a 20-in. picking belt has been installed. From the ball mills the ore crushed to 10 mesh, falls into an ore bin which delivers to a 12-in. belt conveyor that feeds two duplex Merton roasting furnaces. The roasted ore is elevated on an incline to two tube mills for sliming the ore, the gold being very finely divided. It is then cyanided with air agitation in six vats, filtered in two Ridgway filters, and the gold precipitated in the usual way on zinc shavings. The whole plant is electrically driven, a 3-phase current being used.

Other sections of France are now being prospected for gold mines by various companies. The Société de Recherches Minières Françaises claims to have found in the center of France some promising ore-

REDUCTION PLANT—MINES D'OR DU CHATELET, FRANCE

French Government in 1907 for an area of 800 hectares. An enlargement of the property is now demanded. Ore of high grade was found there, and many shipments averaging 200 grams (about 7 oz.) per metric ton have been made. The ore is a quartz with a very small percentage of mispickel, and telluride of gold. It does not carry more than 5 or 6 per cent. of arsenic, sulphur and tellurium taken as a whole, but none of the gold is free milling. The main shaft is now down 94 meters and from it two lodes are worked. Another group of veins will be worked from a new shaft that has been sunk at present to 60 meters. It is reported that the average gold content of the veins found on the company's property is 45 grams per metric ton.

The reductions works installed on the property during the prospective period is now being dismantled and replaced by an entirely new plant of 100 tons daily capacity, divided into several units. The first unit

bodies similar in character to those of la Bellière mine. I might also mention the plant of the Carballino Gold and Arsenic Mines, Ltd., at Harfleur in the department of Seine Inférieure, close to Havre. This company owns in Spain in the province of Orense at Carballino an auriferous mispickel mine, the ore from which is concentrated on the property. The concentrates are shipped to Harfleur where they are roasted in a Brown furnace, 7 ft. 6 in. by 60 ft. The gold is amalgamated, and the arsenic is recovered in brick dust chambers.

A new syndicate has been organized to work 24 mica base-metal claims of an area of about 334 acres, situated on the Oliphant's river, Zoutpansberg (*Min. Journ.*, Feb. 13, 1909.) The plan of the company is to treat the product on the ground, as heretofore high transportation costs have made the exploitation of these claims unprofitable.

Analysis of Proposed Change in Power Contract

An Examination of the Proposal Reveals That There Is an Increased Expenditure Due to Unity Power Factor Clause and Peak Load Penalties

BY ROBERT SIBLEY*

Power plants designed a few years ago, with presumably ample equipment to supply their demands for years to come, have in certain sections of the country found their capacity wholly inadequate for the needs of today. Realizing this condition of affairs, one great water-power company in the Northwest has introduced a novel and clever system of penalties for peak loads. The idea in view is to force the consumer to do away entirely with peak loads, and by making him pay for his power on the unity power-factor basis, to force him by means of synchronous motors to make the current keep as nearly as possible in phase with the electromotive force.

These conditions are certainly ideal for the power company, as they can then realize the utmost from their vested equipment. It has been argued that the new conditions will mean cheaper rates to the consumer. The data of an ex-

THE PROPOSED NEW CONTRACT

During recent years the consumer has needed more power and instead of allowing him to raise his minimum on the old basis, the following is proposed by the power company and argued that it will result to the consumer's advantage:

The minimum monthly bill is to be \$1675, which will allow the consumer to use 219,000 kw.-hours. The consumer must not exceed a maximum of 500 kw. and a penalty of \$3.35 is imposed for each kilowatt lasting five minutes, or over, above 500 kw. For every dollar thus paid the consumer is given an additional 130 kw.-hours in excess of the 219,000 kw.-hours. Any power used in excess of these grants must be paid for at the rate of \$0.0112 per kw.-hour. After six months a new minimum bill shall be established at \$3.35 per kw. for the lowest maximum recorded during the preceding months. Each dollar advance in the mini-

supply of power from the power company that advantage might be taken of the peak-load penalties and thus juggle the power consumption so that the excess at \$0.0112 per kw.-hour would never appear against the company. This could be made possible were it not for the unity power-factor clause that has been inserted by the power company entailing virtually a raise of 18 per cent. in the cost of actual power. As the load is so varied and the cost prohibitive for the installation of synchronous motors it is practically impossible to improve the power factor any appreciable amount.

In order to see how completely the turbine generator would dovetail as mentioned above, it was necessary to find out the exact cost per kw.-hour for generation of electric power by means of the steam turbine. In the series of tests performed, it was found that the turbine was equal to every guarantee of its makers, but the

GRAPHIC RECORD OF CURRENT USED, SHOWING HOW POWER COMPANY IS RELIEVED OF PEAK LOADS BY THE TURBINE

haustive series of tests, however, indicate that the new system will involve a large increase in the annual expenditure in at least one case. It is certainly true that it is to the advantage of both power company and consumer to have a uniform load at all times and to keep the power factor as near unity as possible. This is a matter of coöperation on the part of both parties, and in justice the burden should be borne by both alike and some system should be evolved by which the consumers can realize a saving as well as the power company, in case they can meet the new conditions.

Under the old system a certain consumer has been using power under a contract which calls for a minimum monthly bill of \$1200 and allows therefore a consumption of 156,000 kw.-hours with 400 kw. as a maximum ever to be used; true power to be the basis of measurement, excess of 156,000 kw.-hours to be paid for at \$0.0112 per kw.-hour.

*Consulting hydraulic and electrical engineer, Missoula, Mont.

imum bill again allows the consumer 130 kw.-hours additional and energy consumed above this amount is again to be charged for at the rate of \$0.0112 per kw.-hour. Energy is to be paid for on the basis of unity power factor and each minimum bill thus established can never be reduced during the life of the contract.

The particular company for whom this test and compilation was undertaken is equipped with a hydraulic auxiliary and also a Curtis steam turbine. This turbine is of the following type: 60-cycle, 3-phase, 4-pole, 2300-volt, 126 amp. per phase, 1800 r.p.m. For 10 months the turbine had been kept in continuous operation during the 10 hours of the day shift and had been given all the peak loads to handle, which it did in an admirable manner.

UNITY POWER FACTOR CLAUSE

Tabulations of every cost were kept during this entire time and it was hoped that the turbine thus carrying the peak loads might be made to so dovetail with the

peculiar conditions necessitated in carrying the peak load and the high price of very inefficient fuel made the cost of power production so high that it has been decided to reserve the turbine for emergencies only in the future. The cost of production of power was considered from two separate standpoints, one of which is to charge a fair rate of interest and depreciation against the turbine, and the other was to consider the turbine as already paid for and thus obtain the lowest actual monthly cost.

COST OF TURBINE OPERATION

The accompanying tabulation shows the actual cost for nine months' operation of the Curtis steam turbine. In all cases maximum costs are considered as those in which interest and depreciation and a portion of attendance charges are set against the turbine. By the installation of the turbine the engineer who formerly attended to the compressor alone now operates both. To be fair, however, a

portion of his time has been charged in low especially as relates to future operations. A large electric compressor is now the maximum case.

TURBINE OPERATING COSTS.

Month, 1908.	Hours Run	Kw.-Hours Produced.	Labor Cost, Maximum.	Labor Cost, Minimum.	Wood Cost.	Repairs and Maintenance.	Interest and Depreciation.	Total Cost Maximum.	Maximum Cost per Kw.-Hour, Cents.	Total Cost, Minimum.	Minimum Cost per Kw.-Hour, Cents.
January.....	250	23,170	\$250	\$125	\$ 285	\$40	\$300	\$ 876	3 79	\$ 451	1 95

August.....	278	83,580	278	139	1032	40	300	1650	5 97	1211	1 45
September.....	239	59,470	239	119 50	735	40	300	1314	5 50	894 50	1 50

The table represents every-day costs as they were met in the nine months' time. A special test was put through to find what would be the costs, running under the most ideal conditions for expense of wood, labor and electric generation ever to be experienced on the company's plant. Several days' run gave the results shown herewith and from

IDEAL TURBINE COSTS.

	Maximum.	Minimum.
Wood.....	\$50 00	\$50 00
Labor.....	10 00	4 37
Repairs.....	1 33	1 33
Interest and depreciation.....	10 00	
	\$71 33	\$55 70

these ideal circumstances, which are at the turbine might be continuously operated at a load of 500 kw., or fully loaded, the consumer might expect to generate his power at 1.12 cents per kw-hour, if interest and depreciation be not counted, and at the rate of 1.427 cents per kw-hour if the same be charged against the turbine.

POWER FACTOR AND DISTRIBUTION

To obtain some idea of the general distribution of power throughout the company's workings, a careful set of data was taken in January and the percentage determined as indicated in the accompanying table. This represents average conditions fairly accurately with the

POWER PROPORTIONS.

Department.	Kw.-Hours.	Cost of Power.	Cost per Kw.-hr.	%

exception that the percentage of power as used by the air compressor is unusually

low especially as relates to future operations. A large electric compressor is now

being installed. Most of the compressed air has usually been obtained from a Nordberg cross-compound compressor driven jointly by steam and a hydraulic unit owned by the company. In the above tabulation most of the peaks are caused by the D. C. haulage, elevator, sawmill and rock house.

In order to get at the average power factor of this particular consumer, conditions were varied as far as possible during October, 1908. From the tabulations shown, it is seen that the power factor

POWER FACTOR.

*Transformers for voltmeter have ratio 2200/122

of this installation is 80 per cent. or under for a load of 300 kw. or less, and 85 per cent. or over for a load of 450 kw. or over. From the average conditions noted during the test a power factor of 82 per cent. was decided upon. The installation of the new electric compressor will still further lower this power factor.

PEAK LOAD PENALTIES

The accompanying automatic graphic record of total amperes was taken from the power company's line on Oct. 23, 1908. From C to B the turbine was closed down and the irregular curve shown is thoroughly characteristic of the periods when the power company is carrying the full load of the consumer. From B to A the steam turbine was again in operation

and the resultant curve is also characteristic of the manner in which the turbine relieves the power company of all peak loads.

The high point reached at D is not considered as a peak as it was only momentary. At this point a short-circuit in the electric tramway occurred and the circuit breaker was thrown. From F to E, however, we have an average peak of 200 amp., and as this lasts for five minutes or over it is the maximum load occurring. As a matter of fact this is the average maximum peak that has occurred during the nine months' previous run.

The voltage at the secondaries of the transformer is 2300 and the system being 3-phase, this would give a peak of 800 kw., or 300 kw. above the allowable load. Hence the company would be penalized \$1005, which added to the stated minimum charge of \$1675, would make the minimum bill for the month to be \$2680. According to the new contract the consumer is to be allowed 130 kw.-hours for every dollar so paid. Consequently the consumer is allowed 349,650 kw.-hours. If all this power can be used and if power were measured as true power and not kilo-volt-amperes this would doubtless be ideal for the consumer and at least equal to the old basis. The operation of these two conditions, however, is best shown in the practical application as is found in our deductions below.

ANALYSIS OF PROPOSED CONTRACTS

Having gotten the above data together, eight different propositions for signing a contract with the power company were then considered as follows: (1) On the basis that the power company would sign a new contract similar to the old one, but raising the minimum to 300,000 kw.-hours. (2) That the power company would agree to omit the unity power-factor clause from the new proposal. (3) That the old contract continue in force and the steam turbine be shut down, thus calling upon the power company for all the electric energy consumed. (4) That the consumer sign on the basis of the new contract proposed by the power company. (5) That the consumer continue as previously with the old contract and run the turbine to carry the peak loads, considering turbine costs on minimum basis above mentioned. (6) That the consumer continue as previously with the old contract and run the turbine to carry the peak loads, considering turbine costs on maximum basis above mentioned. (7) That the consumer generate its entire electric power by operating its turbine alone, considering turbine costs on minimum basis above mentioned. (8) That the consumer generate its entire electric power by operating the turbine alone, considering turbine costs on the maximum basis previously mentioned.

Summarizing the costs for the first nine months of 1908 and making a proportional figure for the annual cost of operation, we have the yearly power expense for the eight different proposals outlined in the accompanying table. Thus it is seen that if the power company would allow the consumer to continue on the old contract basis at the same time raising the monthly minimum from 156,600 kw.-hours to 300,000 kw.-hours, the power company would then have an assured minimum monthly account of \$2298 instead of \$1200, and the company would save annually \$13,110, or a net gain of 31.6 per cent. Or, if the power company would not insist on the unity power-factor clause being inserted and otherwise put the new contract into effect the company would save \$11,170 annually, or a net saving of 26.9 per cent.

Without either one of these concessions, it would be far wiser for the company to shut down its turbine and

The Copper Mines of Algeria

The Kef Oum Theboul mine, situated 11 km. to the southeast of La Calle, has been extensively developed, but is not now in operation, although it does not appear to be exhausted. The deposit consists of a wide vein of chalcopryrite mixed with blende and argentiferous galena in schists and sandstones. Samples of the pyritic ore showed 2 to 14 per cent. copper and 400 to 1500 grams (14 to 53 oz.) of silver to the ton.

The Ain-Barbar mine, 22 km. from Bone, yields a complex sulphide ore for the treatment of which experiments are now being made. The Achaiches mine, 36 km. from Collo, is operating in a deposit of cupriferous pyrite in old schists. The Cavallo mine, 18 km. west of Djidjelli, has been worked but is now idle; the ore is found in a lenticular mass, consisting of complex sulphides in igneous

Cuivres d'Algérie. The ore is in the form of gray copper, containing about 2.5 per cent. of metal. A considerable amount of exploration has been conducted on other parts of the same concession, which has an area of 3800 hectares.

Gold and Copper Deposits of Rumania

Vein deposits of gold have been discovered in the Jiu valley, and in the Stan valley in the Lotru mountains. These deposits, according to the Rumanian engineer, Pasco, in the *Monteur Commercial Roumain*, consist of quartz veins in crystalline schists. Alluvial deposits have been known and worked for many years in the valleys of the Lotru, Jiu, Olanesti, Olt, Arges and other rivers. At Dobroudja, gold has been discovered in the sands adjoining the copper deposits, and it has also been found in the quartzites and chalcopryrites of Carapelit. A new and important deposit carrying as much as 60 grams of gold to the ton has been discovered at Kiutukluk.

The copper deposits, however, are of more definite value. They occur in three districts: Mehedinti, Dobroudja and Suceava. At Baia-de-Arama in the first mentioned district, and throughout almost the entire zone of serpentines and andesites are found veins of chalcopryrite. The mineralized zone is extensive and continuous, and the geological occurrence is identical with that at the great Servian mine at Bor. In Dobroudja, numerous discoveries of copper ores have been made near the center of the Tulcea district, notably at Akpunar and Altantepe, at which localities considerable development has been done.

The Cape to Cairo Railway

Railhead is still at Broken Hill, 375 miles north of the Victoria falls, where it has been pending the negotiations as to the construction of the extension northward. This has now been arranged. From its present terminus the line will run due north as far as the Congo border, and will strike northwest along the copper belt, past the mines belonging to the Tanganyika Concessions, as far as the Star of the Congo. It is hoped that the new section will be completed this year, and that copper from the mines near the frontier will be shipped out over the Rhodesian system before 1910. When the boundary is reached there will be about 2200 connected miles of railway from Cape Town to the Congo. It is probable that extensions will be made northward in the Congo territory. The Cape-to-Cairo railway is no longer a dream; at present it is possible to travel from Alexandria to Cape Town by rail or steam except for a distance of about 600 miles.

YEARLY SUMMARY OF COSTS ON EIGHT DIFFERENT SCHEMES.

Total Cost 2,681,478 Kw.-Hours.	Total Cost 9 Months' Run.	NineMonths' Gain or Loss.	Yearly Gain or Loss.	Per Cent. Gain or Loss.	Cost Per Kw.-Hour.	Cost Per H.P.-Year.
Scheme No. 1	\$21,344 30	\$9,849.22 Gain	\$13,110.00 Gain	31.6	0 795 cents	\$52.20
Scheme No. 2	22,804.00	8,389.52 Gain	11,110.00 Gain	26.9	0 851 cents	55.90
Scheme No. 3.	25,107 60	6,085.92 Gain	8,110.00 Gain	19.5	0 936 cents	61.50
Scheme No. 4	26,137.05	5,056.47 Gain	6,740.00 Gain	16.2	0 975 cents	64.10
Scheme No. 5	27,307.02	3 889.50 Gain	5,180.00 Gain	12.5	1 019 cents	66.90
Scheme No. 6	31,193.52	0 00 Loss	0.00 Loss	—	1 162 cents	76.40
Scheme No. 7.	29,797.00	2 489.98 Loss	3,320.00 Loss	12.2	1 112 cents	73.10
Scheme No. 8	38,212.00	7 018.48 Loss	9,350.00 Loss	22.5	1 427 cents	93.70

purchase its entire power on the old contract basis and pay \$0.0112 per kw.-hour in excess of the 156,000 kw.-hours now allowed them on their minimum payment. On this basis of operation, it is seen that the consumer would save \$6740 annually and net a saving of 16.2 per cent.

The question of peak loads and unity power factors is becoming a serious problem in all of our overloaded power plants of today and it presents a problem upon which much can be said on both sides. It seems to me that some system should be devised whereby the consumer might be spurred on to maintain ideal conditions by holding out to him a reward for doing so, rather than whipping him into line by making him pay more than formerly when the power company would also profit by an increased income on practically the same vested outlay.

At the Premier diamond mine, South Africa, during 1908, according to *South African Min. Journ.*, Jan. 16, 1909, 2,078,825 carats were recovered, or an average of 0.25 carats per truck-load. During 1907 the working cost was 28.0d. per load.

rocks. The Tadergount mine, 34 km. southeast of Bougie, has opened a group of veins containing gray copper and oxides, in schist and Liassic schales.

The Djebel Ouenza mines belong to the Compagnie des Mines d'Ouenza, and are situated near the Tunisian frontier, 25 km. from the station of Clairfontaine, on the Tébessa railroad. It is a deposit, originally sulphides, but now covered by an immense capping of cupriferous hematite. The ore contains copper oxides carrying grains of argentiferous copper. This is the most important copper mine in northern Africa.

The Bou-Kadra deposit is the property of the Compagnie de Mokta-el-Hadid and is situated a little north of Ouenza. It consists of copper-bearing pyrites veins running through a mass of hematite which also contains copper and manganese. The Mouzaïa deposit consists of a capping of iron ore traversed by veins of argentiferous gray copper, with masses of copper oxides and pyrite veins. The development of this deposit was once active, but little work has been done since 1876.

The Hendjir deposits are 14 km. west of Ain Seïra (Oran), and belong to the Compagnie Industrielle et Minière des

Mining Coal with Machines in England

Detailed Costs Show That Economy in Mining Results More from Increasing Value of Coal Produced Than from Reducing Working Costs

BY GEORGE R. DIXON*

In working thin seams of coal a serious item in the working cost is the shooting of the stone canches to make the necessary height in the gateways.

At many collieries where the grade is easy, the necessity for shooting very thick stone canches is obviated in some measure by doing the hauling by hand. The cost of stone is in these circumstances much less than when ponies are taken into the face, but the cost of haulage is higher. Face conveyers were introduced with the idea of doing away with haulage altogether and saving that cost, as well as

whether some of the contributors are still in the same sanguine frame of mine. It seemed to me in reading some of the detailed descriptions given, that it was extremely unlikely that the production of coal would be cheapened by the new method. The ability displayed in the application of the conveyer system in varying circumstances, was worthy of the highest commendation. In one particular case the method of face timbering described was most ingenious. It was at the same time laborious. I have had good opportunities of comparing the conveyer system with

L, M, N and O. On each face the coal is undercut by a disk coal-cutting machine. All the roads are driven in front of the cutter faces. In the case of the roads B and D this is done for the following reason:

Fig. 3 is an enlarged plan, and Fig. 4 an enlarged section of one of these roads. The stone below the seam must be shot of such a thickness that the conveyer end can project over the cars on the mothergate rails. It must be possible to pass the cars through, one after the other. To be able to do this, the mothergate is kept at least 30 yd. in front of the conveyer. Two ways are laid in the mothergate. The empty cars are driven past the conveyer, and then on moving, the points can be passed under the conveyer end, on the other way. As the cars are filled they are run forward, made up into sets and driven away.

The usual practice is for the coal-cutting machines to cut out into a stable. To form this stable the roads A, C and E are driven a yard or two ahead. Fig. 5 is a plan, and Fig. 6 a section of one of these roads. It will be seen that in this case a top canch is ripped, and only wide enough for a single way. It will be seen on referring to Fig. 3 that side coal is taken off to form a stable at the mothergate end, wide enough for the machine to rest in, and clear of the mothergate.

VOLUME OF STONE TO BE HANDLED FOR A SPECIFIED CUT

The bottom canch in the mothergate B is shot 10 ft. wide at the bottom and 3 ft. 6 in. thick. The drainage in the coal is 12 ft. wide, and the sides of the canch slope up to the coal. The average width of the canch is thus 11 ft., and the stone taken for an advance equal to the depth of a machine cut 4 ft. 3 in., is $11 \times 3.5 \times 4.25 = 163.62$ cu.ft. This stone is filled into a stone car and run back to the conveyer face. It is then thrown up behind the conveyer and stowed away as far along the face as it will last. Four men will be required for this work.

In the barrier place A, shown in Fig. 5, and in section in Fig. 6, a top canch 4 ft. thick is shot down, wide enough at the top to set a 6-ft. long plank. The width at the bottom will be 7 ft. For an advance of 4 ft. 3 in. the stone shot down is $6.5 \times 4 \times 4.25 = 110.5$ cu.ft. This stone is also stowed behind the conveyer, as shown in Figs. 1 and 5. Two men will be required for this work. The length between the packs at each end is not

FIG. 1. SHOWING ARRANGEMENT OF ROADS AND PLAN OF ATTACKING FACE

FIG. 2. THE 402 YARDS OF FACE ARE DIVIDED INTO FOUR CONVEYER FACES

the still more important cost of making the haulage roads.

It was obvious that new items would be introduced into the cost sheets, and these were somewhat problematic. A paper was read before the Institution of Mining Engineers, Great Britain, by S. C. Blackett and R. G. Ware, on the conveyer system of loading at the face, and this paper together with the valuable discussion following it, gave a great impetus to the use of these appliances. I have frequently wondered

the old method, and I propose to take the 400 yd. of face, with coal 2 ft. 10 in. thick, that I took in my last two articles, and go into the question of cost. In doing this I will not describe face conditions with which I am most familiar, but will adopt the arrangement alluded to above.

Fig. 1 shows how I would attack the 400 yd. of face, or to be more exact, 402 yd. I would divide it into 4 conveyer faces. The coal from two faces would be delivered into one main road or mothergate. Fig. 2 is a section showing how the roads are arranged. The roads are lettered A, B, C, D and E. The faces are lettered

*Mining engineer, 14 First Row, Ashington, Northumberland, England.

stowed at all. This is shown in Fig. 1. The coal gotten in *A* is not filled onto the conveyor, but is filled into cars, and comes out on the road *A*. All timber used at the face goes in by the road *A*, and is distributed by being placed in the conveyor and run to where it is required.

Figs. 7, 8, 9 and 10 show how the face is timbered and how the conveyor is moved up. These sketches leave little to be added to explain the process. It will be seen that it is a laborious operation, and as a matter of fact seven men are required to do it. It is important that when the conveyor is left, it should lie in perfect alignment.

Referring back to Fig. 1 let us abstract the hand-hewing and machine-got coal. The length out of the 402 yd. of coal got by hand hewing is in *A*, 18 ft., *B*, 34 ft., *C*, 18 ft., *D*, 34 ft. and *E*, 18 ft., a total of 122 ft. The length the machine cut is $1206 - 122 = 1084$ ft. The cut on each of the 4 faces is

$$\frac{1084}{4} = 271 \text{ feet.}$$

Practically 10 per cent. is got by hand, and 90 per cent. is secured by machine mining.

In some cases the advancing places are undercut by machines of the chain-jig type, or by punchers. I would have only two faces out of the four going at once. Then the others would serve as spare places, if they were so needed, and they are sure to be needed time and again. Suppose *L* and *O*, Fig. 1, to be the two faces going. Then the length hand hewed would be: 18 ft. in *A*, 12 ft. stable in *B*, 12 ft. in *D*, 12 ft. stable in *D*, and 18 ft. in *E*, a total of 72 feet.

THE QUANTITY OF COAL PRODUCED

The coal produced in the 2-ft. 10-in. thick seam, with an advance equal to a machine cut of 4 ft. 3 in. at 19 cwt. per cu.yd. of coal would be

$$\frac{24 \times 0.94 \times 1.42 \times 19}{20} = 32 \text{ tons.}$$

The quantity of coal produced on the two faces, 271 ft. of coal, would be

$$\frac{90.31 \times 0.94 \times 1.42 \times 2 \times 19}{20} = 230 \text{ tons.}$$

Total quantity of coal per day = $230 + 30 = 260$ tons. Allowing 3 tons of coal per shift per hewer, the number of hewers would be $\frac{32}{3} =$ say 11; allowing 9 tons of coal for each filler, there would be

$\frac{230}{9} =$ say 26 fillers, and in addition there would have to be a man placed on the mothergate, to put on the fillers tokens, and assist in passing the cars through under the conveyor end.

One of the difficulties of the conveyor system is, that the fillers would all have to share their earnings. 913 men is a

large number to get to agree. I have known many cases where the filling was let as a bargain. The prices they had to go for, considering that the coal is to fill into the conveyor trough lying within 1 ft. 6 in. of the coal, was very disappointing. The men usually earned wages some 20 per cent. above the wage we have taken as a hewer's wage.

FIG. 3. Plan showing Face of a Mothergate, the Stable to Cut into, and Arrangement of Car Roads.

The Engineering & Mining Journal, N.Y.

FIG. 4. AN ENLARGED SECTION OF ONE OF THE ROADS

FIG. 5. Plan showing Face of a Barrier Road.

The Engineering & Mining Journal, N.Y.

FIG. 6. SECTION OF ROAD SHOWN ABOVE.

There is a deputy in charge of each working face in the day shift, also a conveyor brakeman, and a lad to help with the cars. The cutting of the faces and moving up of the conveyers is done at night. A filler is employed in the mine to keep the cutting machines and conveyers in good order. The motive power

may be compressed air, or electricity. Each face is cut in two shifts of cutters. A man goes in front of the machine setting a plank with a middle prop under it. As the machine cuts along, he goes behind and puts in the end prop next to the coal. The machine man drives the cutting machine. These men are paid the same wages. Four men put in a shift in crossing each face. The cut is made under the coal, and the dirt has to be thrown over the conveyor into the goaf, where a pack is built behind the conveyor, the dirt has to be cast along the face, till it can be thrown into the goaf; 3 men are required on each face for this work.

When the second face feeding each mothergate is advancing, a top ripping is made in the mothergate, and the stone from it is packed behind the conveyor.

A CONVEYER ON THE MOTHERGATE

The stone to pack behind the second face on a barrier is obtained from falls from the sides. It is, therefore, only a thin pack as shown in Fig. 1. It will be obvious that the conveyor end of the second face on a mothergate will need careful watching, as the stone must be very much broken. From this point of view it would be a great advantage to have two faces feeding on to a mothergate progressing in line. To do this, and to avoid having to drive the mothergate a long distance in advance, in some collieries a conveyor has been put into the mothergate. It is supported on cross girders. The face conveyor delivers onto this mothergate conveyor, which delivers the coal into the cars at some distance from the face. In this case the stone obtained in the face of the mothergate is distributed behind the two face conveyers. The mothergate conveyor can elevate the coal, as well as deliver it behind, if necessary. It is thus not necessary to shoot such a thick bottom carch. However, any advantage got from this would be balanced by the fact that in ripping the second carch off-hand stowage would not be available for the stone.

There is another important advantage that can be claimed for this method. On referring to Fig. 1 it will be seen that the mothergates *B* and *D* will be difficult to ventilate. It will be obvious that any method which shortens the distance that these roads must be in advance of the face air current, must be of considerable benefit.

Continuing our consideration of the working of the faces *L* and *O*, referring to Fig. 1, it will be seen that the coals from the roads *A* and *E* must be driven out on these roads. This lead of necessity is often a long one. The whole of the roads are cut off periodically by a cross road, so that the distance for horse haulage is shortened, and the electric or compressed-air mains kept within reasonable distance of the face. The cost of

these roads must not be overlooked. Again there is a considerable amount of dead work to be done in preparing conveyor faces when first beginning, and a fair conception of it can only be got by keeping out the cost over a long time. Let us make a calculation similar to those I made in my previous articles:

26 men filling on the 2 faces, 2 men on the mothergate putting on tokens and passing cars under the conveyor, producing 230 tons at 26c.	\$59.80
10 hewers in advancing places producing 30 tons at 68c.	20.40
8 men working cutting machines at \$1.92 per shift.	15.36
6 men cleaning dirt and casting it into the goaf at \$1.32 per shift.	7.92
The last two items are special work and will be done by piece work, therefore add.	
Supervision proportion for 260 tons	4.80
2 deputies at \$1.68.	3.36
2 coal putters in barrier places at \$0.72.	1.44
2 conveyor drivers at \$1.20.	2.40
2 conveyor helpers at \$0.96.	1.92
1 filter at \$1.68.	1.68
1 changemen for men moving conveyers at \$1.68.	1.68
14 men engaged in moving conveyers and face timber at \$1.92.	26.88
2 inspectors and changemen for stonemen on road at \$1.44.	2.88
10 stonemen doing work on roads in face at \$1.92.	19.20
4 men repairing roads at \$1.92.	7.68
92 shifts.	\$179.90

Cost per ton = $\frac{179.90}{260} = \$0.69$.

The cost per ton for putting and cleaning = $\frac{15.36 + 7.92 + 4.80}{260} = \$0.108$.

The cost per ton for hewing and filling = $\frac{59.80 + 20.40}{260} = \$0.31$.

Tons per shift = $\frac{260}{92} = 2.83$.

A COMPARISON OF COSTS

In my last article I showed how the saving cost of 15.6c. per ton, which at first sight appeared to be the result of the putting in coal-cutting machines, very soon disappeared on a closer examination. We have just found a working cost, when using face conveyers in connection with coal cutters, of 68c. per ton. The cost of coal putting with ordinary gateways was 76 cents. This represents a saving of 8c. per ton when using conveyers.

The labor cost for repairs, and pipe or electric main laying will be more. The cost per ton for power and interest and depreciation of capital sunk in plant is sure to be more. The cost per ton for timber with a projecting roof ledge of 11 ft., instead of 5 ft., will be much more. The use of conveyers makes it imperative to have a large siding for cars near the conveyor, and the proportion of cars must be much higher than when the other methods we have considered are applied.

When new faces are being prepared the cost per ton on coal mined at that time is high, and it is only fair that all costs connected with conveyers should be included. Again, the costs have been worked out on the assumption that the conditions given are average conditions. So they are, but we must remember that

there are times when the fillers fail to clear the face, when there are faults or swells on the face, and there are breakdowns of cutter machines or the conveyers; all the subdivisions of labor must work together with exactitude.

If one division is delayed, the whole scheme is thrown out of joint with necessarily an increased cost. Summing up the above I suggest that the 8c. can be struck off as a possible saving, and we must look elsewhere than the decreased working cost to pay us for introducing conveyers. Remember another fact, that from the 400-yd. face, using conveyers as described, 260 tons of coal would be obtained as against

as a profit, the adoption of conveyers is certainly worth while.

It is an evident fact that machinery cannot be introduced into the face of a mine without increasing the danger to life. The skilled miner trusts to his ears in great measure. When the language of the rock becomes menacing he knows he must take precautionary measures. When a coal cutter is working, these sounds are drowned in the noise of the machine. When conveyers are used this is especially so. This does not constitute the only source of danger. It is possible to become entangled in some part of the mechanism, and when electricity is used there is the

FIG. 7. SHOWING INITIAL POSITION OF CONVEYER AND PROPS

FIG. 8. BOTH THE CUT AND TIMBERS HAVE BEEN EXTENDED

FIG. 9. THE CONVEYER IS THEN MOVED CLOSER TO THE FACE

FIG. 10. THE GOAF IS ADVANCED AND A NEW CUT MADE

170 tons by the coal-cutting alone, and 350 tons with hand-hewing. On the other side there is first the increased output per person employed at the face. Then by using conveyers the percentage of large coal is increased by 5 per cent, that is, from 70 to 75 per cent. Taking the selling price for large coal at \$3.36, and for small coal \$1.68 per ton, the average selling price will be 0.75 of \$3.36 + 0.25 of \$1.68 = \$2.04 per ton. When the percentage of large coal was 70 the selling price averaged \$2.85. There is, therefore, an increased price for vended coal of 9c. This is certainly of great importance, and if there is a fair prospect of securing it

danger of death from shocks. Many such accidents come to my mind as I write. With a compensation act in force, all this has a financial as well as a sentimental side.

COAL CUTTERS ARE NOT ADVISABLE WHERE FAULTS OCCUR

I have assumed in working my costs that conditions are good in each case. But conditions are not always good. The seam does not lie regular; faults and swells occur. Every engineer knows what this means. If he does not know by experience, he can readily appreciate the fact that these conditions will be more ad-

verse to the continuation of machine mining than hand mining. The former can never possess the flexibility of the latter. It is an axiom that coal cutting cannot be successful where many faults occur, and conveyers are quite out of the question.

In almost all mines there are special zones where faults are most numerous. In these mines coal cutters and conveyers may be introduced; however, they are put into the best parts of the pit, while the difficult parts are kept on hand hewing. This is where many misleading figures come from.

In my first article I found a face cost for hand hewing to be 92c. per ton. Under adverse conditions in a particular part of the mine this might have been 8c. per ton more. If in this particular mine, the cost

and if the same close supervision was given to it as is given to machine mining, it is doubtful if the latter could show the advantages claimed for it.

In answer to the question as to whether machine mining pays, I have shown by the examples taken, that generally it can be made to pay. This is done not by reducing working costs, but by increasing the value of the coal produced. In working thinner seams than I have referred to, it is probable that a saving could also be secured in working costs.

The power required to lift a quantity of water depends upon the height to be raised, and, like the problem of winding, the slower the speed and the larger the quantity dealt with per stroke, the higher

Economical Development of Coal Mines

By H. J. NELMS*

In the design of coal mines, the engineer loses sight of the fact that occasionally there is a sudden rush of orders equal to double the quantity of coal the plant may normally be producing. If the mine cannot produce this coal, the manager usually wants to know why. Here lies one of the great evils the engineer or superintendent has to overcome, and here also is one of the most common causes for waste in mining.

I have known superintendents and engineers to attack their stumps, ribs and

From Engineering & Mining Journal, N.Y.

GENERAL SCHEME FOR DEVELOPING A COAL SEAM, WHERE UNUSUAL OUTPUT DEMANDS ARE ANTICIPATED

(as found in my second article), for a coal face be 77c., the saving appears to be much more than it has any right to be considered.

We are now, in fact, comparing good conditions for coal cutting, with bad conditions for hand hewing. This is obviously unfair. It may be taken as a rule that where coal-cutting face costs and hand-hewing face costs are given from the same seam, in the same mine, the coal-hewing face is not getting a fair representation, and the comparison is worthless.

The same remark can be applied to the percentages of large coal with equal truth, systematic way, and calls for constant and close supervision by the head officials.

If ordinary longwall, with hand hewing, was applied in the same systematic way,

the efficiency. This problem of pumping, however, is largely influenced by the initial cost of the plant, and it may be cheaper to install a high-speed pump with a low efficiency and a low capital cost than to install a high-efficiency slow-speed type of pump at a larger cost, when question is mainly affected by the cost of the power.

M. Marchand states (in *Echo des Mines*) that the timber covering three deposits of magnetite, recently discovered near Bagnères de Bigorre, is frequently struck by lightning, although the woods are situated in hollows, while the adjacent ridges are rarely struck. This is ascribed to the higher attraction of the magnetite.

even new coal in a mad desire to fill these orders, and when the rush is over, they usually lose more coal than they have just produced. The accompanying drawing shows a plan that will enable a superintendent to produce better results than any similar room-and-pillar method.

THE ADVANTAGES THAT RESULT

One of the great advantages that would come from using this plan of development would be, that with the same machinery, the tonnage of the mines could be doubled by only increasing the number of men employed. This method would also isolate the men from each other, for only one butt entry would be

*Mining engineer, Bontleyville, Penn.

mined at a time, and separate splits of air could be used for each of the working butts.

Here you have short hauls for either locomotive or mules, whichever is used. Also short moves for mining machinery, for at least one machine will be required on every working butt; if mules are used, electric wires can be kept entirely off the working butt, and strung on some entry which is not working; jumpers can be used across the different breakthroughs, and if locomotives are employed, an operator can then be sure his locomotive will be on a haul where it can produce at least 100, 2½-ton cars; any number of cars less than this will raise the cost of haulage above that incurred with mule power.

The American coal operator does not seem to take kindly to standardizing his coal mines to a proper distance between butts and between main entries and face entries. I remember one mine in particular where we had to drive our main entries nearly 1100 ft. before we turned a set of 480-ft. butts. This plan was far from being correct, for an operator can't help finding some tracts of coal in every field, which it will be impossible to mine.

The accompanying plan shows three main entries, the center main being used both for locomotive haulage and as an intake airway. This system is designed to give easy curves for haulage. The cross-cuts are made every 100 feet.

The face entries are driven parallel to the mains from 1400 to 2000 ft. away, the smaller distance being used for 5-ft. coal. Here again the center entry of the three is used for an intake airway and also for haulage.

The butts are driven with 450- or 500-ft. centers and are turned at right angles off the main entry. The butt entry and its air-course are driven on 50-ft. centers. The rooms are turned 90 deg. off butt entries, and are driven 25 ft. wide for a distance of 250 ft., where 500-ft. centers are used between each set of butts. The ribs between rooms under these conditions should be from 13 to 15 ft. with breakthroughs every 100 ft. The rooms are all cut across at the 250-ft. mark. The protecting pillar between rooms and entries should be from 60 to 70 ft.; the cover overlying the seam deciding this.

The plan here outlined is sure to meet with success where an operator desires to keep his mines up to a standard point of development; he can also feel assured that the only step he need take to increase his normal output is to employ more men. American mines are conceded to be the worst in the world for spreading out over a great area, and not producing nearly the amount of coal that could be mined if operations were confined more to certain districts.

Colliery Notes

In some coalfields it is common to find the seam cut by an igneous dike, varying from 5 to 40 ft. in thickness. At such localities it is often a question how far into the coal seam the prejudicial effect of the dike extends. Experiments carried on at the St. George's colliery in Natal, to ascertain this uncertain point, resulted in proving that 18 ft. away from the dike contact the coal is practically unaltered. The dike in this latter case was 22 ft. thick. It was also shown that the distance affected does not bear a uniform ratio to the thickness of the igneous body.

Among other reasons for the waste in coal mining, is the practice of many operators in mining only the low sulphur areas of coal seams. This is caused by the discriminating trade the mine manager has to deal with. In some States, Massachusetts for instance, such regulations are in force, that the manufacturer of gas is absolutely confined to the use of low-sulphur coals. The amount of sulphur contained in gas is naturally a function of the percentage of sulphur in the coal from which the gas is made. It will not be many years before those coals containing less than 1 per cent. sulphur, will be practically exhausted. When this time arrives, the gas manufacturer will have to use high-sulphur coal and adopt more economical methods for purification.

English colliery owners are now using reinforced-concrete construction for a variety of purposes, both on the surface and underground. One of the latest installations of this kind was that at the Dawdon colliery where reinforced concrete is utilized for the tippie-house floors. The area covered is about 2500 square yards. The main girders consist of rolled-steel joists of 35-ft. span and placed at 11- to 14-ft. centers. Between these girders are placed secondary beams, 16x8 inches, with about 6-ft. centers. This floor is at least 40 lb. per sq.ft. lighter than any other method proposed; the large span of the main beams adds considerably to the potential live strength of the floor. This plan of using reinforced concrete construction has proved most satisfactory where perfect rigidity is an absolute necessity, and it is stated that this system lends itself admirably for such heavy colliery works as hoppers, shaft linings, water-storage tanks, foundations in unstable soils, etc.

Concerning the initial processes that have occurred in forming our coal seams, one English authority still contends that our coal beds were formed by forests growing up, after which a depression of the earth's surface occurred, swamping the forest with water. This same writer tells of experiments where an attempt has been made to produce coal artificially in

the laboratory. He states that when a piece of wood is placed in a sealed tube and heated from 200 to 300 deg. C., the wood becomes something similar to a mass of charcoal; when heated above 300 deg. C., it resembles a lump of coal, and when a heat of 400 deg. C. is applied, the material is similar to anthracite. Along this line a French geologist says the conversion of vegetable matter to coal is due to the action of bacteria. The action of bacteria may be seen occasionally upon a heated damp haystack. The presence of moisture is essential to produce bacterial action. The center of haystacks sometimes get so hot as to heat the end of an iron bar to redness. When the heat has reached, say 100 deg. C., the bacteria are killed, and chemical changes, such as oxidation, take place. Those authorities who assert that pressure is the great transforming agent call attention to the fact that the deeper we go down through a peat bog the fainter are the traces of the vegetation, until the vegetable origin can scarcely be recognized; however, on the surface of the same peat bog we have living plants.

There is a divergence of opinion as to the advisability of providing baths and a wash house near the mouth of coal mines for the use of employees. In a number of instances the opponents of this plan base their objections on the fact that at many mines where the wash houses have been provided, the miners have failed to avail themselves of the opportunity to use them before going home. It is even claimed that the majority of coal miners prefer not only to go home in their working clothes, but also evince a desire to eat their evening meal in this uncleanly condition. Only recently a competent authority advanced many arguments to prove that this latter course of action on the part of the men was most beneficial. Since bath houses fitted with lockers and showers are so popular at the large iron mines of Michigan, as well as other metal operations, it seems incredible that such sanitary arrangements leading to both comfort and cleanliness on the part of the men, should lack favor at our coal mines. It is for this reason that the outcome of experimental bath-house installations in Great Britain will be awaited with interest. At one of the large collieries in Scotland, where 1100 men are employed, an elaborate system of baths is being installed. At this mine it is proposed to take the names of the workmen who are willing to make use of the baths and pay 2c. per week toward their maintenance. This sum is barely half of the anticipated cost of providing the desired facilities. At dozens of mines in the United States the miners are obliged to travel 8 or 10 miles by trolley or train to and from their work. It is hard to believe that these men would not favor a plan that would enable them to go back and forth in clean, comfortable clothing.

The Mount Morgan Metallurgical Works

Three Distinct Methods of Treatment Are Employed, Chlorination, Chlorination after Roasting, and Smelting; Separate Plant for Each Method

BY GERARD W. WILLIAMS*

The metallurgical works of the Mount Morgan Gold Mining Company, Ltd., in Queensland, Australia, are divided into three distinct portions: the west works, treating oxidized ore from the open cut; the muddle works, treating sulphide ore from the stopes below the cut and above 500 ft. vertically; and the copper smelter, treating ore from the copper mine.

The west works is the oldest portion of the present plant and was erected in 1868 from designs prepared by the present general manager, Captain Richard. The

a 24x14-in. Blake-Marsden is installed, but Jaques rotary crushers are used on the other units. Under similar conditions the reciprocating crusher possesses the highest efficiency, and maintenance costs are also slightly in favor of the former type.

From the breakers the ore passes to the cylindrical dryer, built of mild steel, 30 ft. long and 6 ft. 8 in. internal diameter. It revolves on three pair of rollers, the base of the rollers being set 35 deg. to the horizontal. The inclination of the

BALL MILLS AND FURNACES.

From the dryers the ore is raised 30 ft. by a bucket elevator to the ball mill bins. The chutes from the bins to the mills are controlled by sliding doors, and one man per shift attends to all 16 mills. Automatic feeders were tried, but the ore varies so much in composition that they were discarded. The cost of regulating by hand amounts to 4c. per ton. The mills carry a load of one ton of 6-in. steel balls, and have a capacity of one ton per hour. The screens have a life of

GENERAL VIEW OF MINE AND WORKS LOOKING NORTHWEST

plant has a capacity of 11,000 tons per month. The ore is delivered into the bins, which have a capacity of 2000 tons, by an electric tram running out from the floor of the open cut. On their way to the bins the trucks are weighed and the weight is automatically recorded.

The mill itself is divided into four units each comprising one ore breaker, one tubular dryer, one elevator and four Krupp No. 5 ball mills. On one section

dryer is 34 in. per foot. The tires are tapered the same amount, the rollers being also tapered so that the line of contact is horizontal. The dryer is built in five sections which are fitted with cast-iron tires riveted to the shell. The dryer is driven by means of a spur wheel bolted to the outside of the shell, and makes one revolution per minute. The lining of locally manufactured fire bricks lasts about 12 months. Wood fuel is used in the furnace and the consumption is 3.3 per cent.

about 50 days. The balls are worn away at the rate of 0.725 lb. per ton of ore, and the total loss of steel from all parts including ball averages 1.6 lb. per ton crushed. Spare balls are added during the periodic overhaul of the mills. This seems open to criticism for it involves the mill's working with diminishing efficiency during the period between overhauls. The method of adding a fresh ball daily, or so many times a week, seems preferable.

All the 16 mills are driven from the

*Consulting engineer, Melbourne, Australia

main crank shaft of the mill engine, being arranged in pairs on each side of the shaft and driven by a $2\frac{1}{2}$ -in. pinion working into a spur wheel $9\frac{1}{2}$ in. in diameter. The mills run at $21\frac{1}{2}$ r.p.m. and require 13 h.p. when running under full load. Each mill can be thrown out of gear by means of a jaw clutch.

From the ball mills the ore falls to the furnace bins. The furnaces are four in number and of tubular type, 43 ft. long. The tubes are built up of boiler plate flanged and stiffened with roller bands so that all the weight is carried on the bands. The bearing and drive wheels are arranged as in the dryers. The diameter of the shell varies from 7 ft. at the upper end to 7 ft. 8 in. at the lower end, and the firebrick liner is 13 in. thick at the firebox end and 8 in. at the upper end. The feed is by means of two eccentrically placed scoops at the upper end of the tube. The scoops dip into a "well" kept filled with crushed ore and in consequence the rate of feed varies directly with the rate of revolution of the furnace, which averages one revolution in $15\frac{1}{2}$ min.; the ore takes about a half hour in passing through the tube.

A separate engine is attached to each furnace for regulating the speed. Two tubular conveyers, water cooled, take the ore from each furnace to the bins above the chlorination vats. The furnaces are wood fired, but a producer gas plant is kept as a stand-by, and is sometimes used to increase the heat when, for one cause or another, the ore requires more roasting than usual.

The chief effect of the roasting is the dehydration of the kaolin ore and a general sintering of the product. Sulphur is only present in the oxidized ore to the extent of 2 per cent.; copper in traces.

The leaching vats are 16 in number, built of brick with cement mortar. They measure 60 ft. long, 12 ft. 6 in. wide and are 6 ft. deep. The capacity of the vats is 200 tons. The leached ore is discharged by sluicing through side doors in the vats.

TREATMENT OF THE ORE.

The treatment of the ore is as follows: From the bins it is distributed to the vats by means of push conveyers, and after leveling off, a water wash is given to cool the ore. After draining, a solution of chlorine water is run on and kept slowly leaching until the effluent liquor smells strongly of chlorine. The vat is then placed "in contact" for eight hours. After the solution has been leached off another chlorine wash is given, followed by a water wash. The actual time consumed is: (1) Water wash to cool ore, 24 hours; (2) chlorine solution, 30 hours; (3) washing out with water, 18 hours.

When the water wash no longer carries gold the contents of the vat are sluiced down the creek. The consumption of chlorine averages 2.5 lb. per ton

of ore. The gold-bearing solutions are pumped to storage vats from which they are delivered to 12 charcoal filters of brick-lined concrete, $10 \times 12 \times 5$ ft., each holding two tons of charcoal. The precipitation is absolute and the effluent liquids from the boxes contain no free chlorine. At present the ore averages 4 dwt. and a recovery of 95 per cent. is effected. The costs for 117,000 tons treated for the year ending May 31, 1908, were: crushing, 87c.; roasting, 93.5c.; chlorination, 75c.; total, \$2.56. The gold-charged charcoal is sent to a central gold refinery for treatment.

Power to drive the mills, breakers, etc., is supplied by a 500-h.p. triple-expansion, horizontal engine. The cylinders measure 15, 24 and 39 in. in diameter with a 24-in. stroke. Five 125-h.p. Babcock & Wil-

cox boilers are installed at the west works. The gold-bearing solutions are pumped to storage vats from which they are delivered to 12 charcoal filters of brick-lined concrete, $10 \times 12 \times 5$ ft., each holding two tons of charcoal. The precipitation is absolute and the effluent liquids from the boxes contain no free chlorine. At present the ore averages 4 dwt. and a recovery of 95 per cent. is effected. The costs for 117,000 tons treated for the year ending May 31, 1908, were: crushing, 87c.; roasting, 93.5c.; chlorination, 75c.; total, \$2.56. The gold-charged charcoal is sent to a central gold refinery for treatment.

From this large conveyer the ore is delivered at any desired point to push conveyers which run on rails over the vats. There are eight vats of 200 tons

CONVERTERS IN OPERATION AT COPPER WORKS

cox boilers are installed at the west works.

THE MUNDIC WORKS.

The ore treated at the mundic works has the following general composition: silica, 68 per cent.; pyrite, 26; copper, 1; and magnesia and alumina, 5 per cent. The gold averages 10 dwt.

The ore breakers are placed at the main incline shaft and after breaking down to 1-in. cubes it is delivered to the mill bins by an electric tram. The bins have a capacity of 2000 tons, and the plant is designed to treat 11,000 tons per month. The plant is divided into two units, each of which comprises one tubular dryer similar to those in the west works, and an elevator for the delivery of the dried ore to the mill bins. The ore is fed to seven No. 5 Krupp mills.

The crushed ore is raised by an elevator

capacity, two of 400 tons and two of 1000 tons capacity. The treatment vats are constructed of brick, set in cement and are provided with sluice gates at the sides for the discharge of the leached ore. The course of treatment is as follows:

(1) Acid wash of 0.2 per cent. sulphuric acid followed by a water wash. This removes about 50 per cent. of the copper which is precipitated in tanks filled with scrap iron. The acid treatment and water wash occupies two days.

(2) Three days' treatment with chlorine solution.

(3) Water wash, from one day in the smaller vats to three days in the 1000-ton vats. The residues are sluiced down to a dam where they accumulate. The spent liquors from the precipitation works are pumped to the dam and the leachings are precipitated in scrap-iron tanks. The

residues contain 0.4 per cent. of copper which is slowly recovered from the leachings.

RECOVERY AND COSTS.

The recovery of gold on 10-dwt. ore is 96 per cent. The chlorine is manufactured from salt and manganese ore, the latter mined locally and the salt obtained from the coastal lagoons. The chlorine is dissolved in towers filled with rubble down which the water flows against the ascending stream of gas.

The 14 ball mills are gear-driven from a main line shaft belt-driven from the crank shaft of a 200-h.p. engine. Another engine of 100 h.p. furnishes power for pumping, etc.

The charcoal from the precipitation boxes in both the west and mundic

Iron island, a small island at the mouth of Kepple bay, 18 hours steam from Rockhampton. The company pays a small royalty and mines the ore with its own men. Two steamers are engaged in bringing ore from the island to the wharves at Rockhampton.

The limestone is obtained from the company's quarries at Marmor, 53 miles by rail from Mount Morgan. The limestone is encrinoidal and contains only 2 per cent. of silica. Delivered into the smelter bins iron ore costs \$4.44, limestone \$1.60, and coke \$9.50 per ton.

The normal daily charge of each furnace is as follows: ore, 200 tons; limestone, 100 tons; iron ore, 45 tons; low-grade mattes (purchased) and converter slags, 15 tons; coke, 40 tons.

The forehearth is circular in shape,

ore obtained from the open cut, and carrying 2.5 dwt. to the ton, cemented together with kaolinized felsite dike carrying a small quantity of black sulphide of copper. A little fire clay, also obtained on the lease, is added to increase the binding capacity of the kaolin. A rock drill mounted by a universal joint from a swing arm is used for tamping.

The blister copper is sampled in the following manner: A wooden templet, in which are 100 holes arranged in rows of 10, is placed over the slab of blister and one hole is rubbed with chalk. A drill sample is then taken with a ½-in. bit at the point marked. As the bars are sampled the holes in the templet are taken in turn and the drillings from 100 bars are mixed and divided for assay. The blister averages 99.1 per cent. copper and

COPPER, MUNDIC AND WEST WORKS, LOOKING NORTH

works is treated at the central refinery. After burning off in large muffles the ash is smelted in a reverberatory furnace with sand and soda, and the bullion is tapped into molds. From the molds the bullion is remelted in large graphite crucibles in circular coke-fired furnaces. The bullion is refined with air which is blown through the molten metal.

The cost of treating 115,000 tons of ore during the year ending May, 1908, was, crushing, 78.8 c.; roasting, \$1,376; chlorination, \$1.01; total, \$3,174.

THE COPPER SMELTING PLANT.

The ore sent to the smelter has the following average composition: silica, 45 per cent; iron, 25; sulphur, 25; copper, 2.5; alumina, 15 per cent. Iron ore is obtained from the company's mine at

12 ft. in diameter and 3 ft. 6 in. deep. They are lined with chrome ore imported from Nouniea (French Caledonia). A small auxiliary forehearth takes the slag overflow from each of the primary ones. The matte obtained averages 45 per cent.

There are two converter stands. When freshly lined the converters take a charge of three tons of matte, and toward the end of their life, averaging six blows, the capacity is increased to six tons. The time of blowing varies from 13½ hours for the first to three hours for the final blow with six tons. On the first charge air at 5 lb. pressure is used for the first hour, the slag is then poured off and the blast increased to 10 lb. From the converters the copper is poured into molds for export. Seven converters are kept in reserve.

The lining is composed of silicious gold

12 oz. gold. It was sold to the Delamar refinery, Chrome, New Jersey, but a large refinery has been erected at Port Kembla, New South Wales, and now the company is refining its blister copper at that place.

POWER PLANT

Seven Connorsville blowers are direct-gear driven by motors each of which delivers 10,000 cu.ft. of air per minute at 35 oz. pressure. For the converters three electric-driven Parsons turbo-blowers at 3000 r.p.m. deliver 3000 cu.ft. of air each at 15 lb.. All power is obtained from the central power station.

The McMurry sintering process is being installed for the treatment of the flue dust which averages 2.25 per cent copper and 4 dwt. gold.

COST OF SMELTING

Under present conditions the cost of production of copper is in the neighborhood of \$250 per ton, but as previously pointed out, mining costs are abnormally high and large quantities of barren flux are used. The company has recently secured an option on the Many Peaks sulphide mine, 1.7 miles from Mount Morgan; a railway to the property is under construction. The Many Peaks orebody has been opened up over a length of 2640 ft. and the width at the lowest level, 470 ft. from the crest of the outcrop, is 48 ft. The ore will be worked by adit levels, and mining costs will not exceed \$1.50 per ton.

The ore has the following composition: iron, 39.96 per cent.; sulphur, 35.48; copper, 2.1; silica, 4.6; alumina, 3.52; calcium carbonate, 5.8; water, etc., 2.0 per cent.; gold 25c. and silver 16c. per ton.

It is estimated that this ore will be landed at the mine for a freightage charge of \$2.05 per ton. It is estimated that with the present plant 100,000 tons of Many Peaks ore will flux 250,000 tons per annum of Mount Morgan ore. Under these conditions the cost of blister copper will not exceed \$165 per ton.

It is probable that advantage will be taken of the reduced freights for back loading to send silicious mundie ore back to Many Peaks for smelting there with the pyritic ore. If this is done it may in time result in the closing down of the chlorination works at Mount Morgan and the treatment of all the ore, excepting the low-grade oxidized ore from the open cut, by smelting.

CENTRAL POWER STATION

All electric power for pumping, for the smelter plant, the electric winder at the main underlay shaft at the mine and general purposes is generated at a central station. The boiler plant comprises nine Babcock & Wilcox boilers generating 1250 h.p., and five Hornsby boilers generating 1000 h.p. The boilers are self-stoking. The plant consists of three Parsons turbines, two of 400 and one of 1000 k.w. capacity, and two Brown-Boveri-Parsons turbo-generators of 400 k.w. each. All the turbo-generators deliver direct current at 500 volts. The domestic lighting plant consists of a motor generator, 25 kw. and 230 volts. The switchboard embraces all the modern improvements.

The compressors are installed in the same building. There are Reidlers, delivering 3000 and 2000 ft. of air per minute respectively, and one Schram compressor delivering 1200 ft. of air per minute. All air is delivered at 80 lb. pressure. For the water supply Permus compound verticals are installed. These pumps raise 750,000 gal. per day against 250 ft. head at a cost of 3.2c. per 1000 gallons.

A horse power costs 20c. per day of 24 hours and electric power is generated

for 1.8c. per k.w. hour. Coal having an actual evaporative power of 6.5 lb. of water per pound costs \$4.35 at the coal bins. Stokers receive \$2.16 and drivers \$2.64 per shift.

ADMINISTRATION

In a large concern such as this the question of administration is of equal if not greater importance than that of actual technical methods. The basis of correct administration lies in the correct apportioning of costs for the various departments; for unless the true costs of every subdivision of the work is accurately known it is difficult, if not impossible, to effect any marked improvement in existing methods.

The basis of all cost keeping at Mount Morgan is the card system, and this system has been extended into every department of the mine. The system is too well known to need description. As a result of the introduction of this system it is possible to do at this mine what is done on no other mine with which I am familiar; at 10 a.m. every morning every officer receives a complete cost sheet for the preceding 24 hours' work.

The importance of this to the smelter bosses and the metallurgist is obvious; its importance to the general manager is even greater. When costs are estimated monthly or even weekly it is not possible to notice the effect of small stoppages or of those interruptions in regular work which result from accident or other abnormal causes. When cost sheets are made up every day the effect of any slight departure from the normal is immediately perceptible and working costs are largely an epitome of unconsidered trifles.

The construction engineer receives cards indicating progress and expenditure on every piece of work under construction. Similar cards are kept for the purpose of rendering a daily statement of all ore raised, treated or stored, of its value and of the chlorination and smelter returns. Fluxes and coke supplies are presented in a similar manner. The system has been extended to the shops, and complete records of every job done are filed. It is therefore possible to compare the relative economy of two methods of work, and to determine the actual working value of various workmen on similar jobs.

Not only has the introduction of this extended application of the card system resulted in the management's obtaining complete control of every department with a minimum of effort, but it has paved the way to marked reductions in the matter of minor working costs where previously the source of loss was undetected. On every hand the system has resulted in the reduction of costs, and a corresponding increase in efficiency.

The transport department of the mine is run on the lines of a railway traffic

office, and the various departments are charged exact and not approximate rates for the handling of their various stores. All administrative, head office and directorate costs are apportioned over the working departments; the mine cost sheet has no "General Expenses" item.

ECONOMY OF THE CARD SYSTEM

The pertinent question as to the cost of the system in all its ramifications naturally arises. As nearly as I could learn it has more than doubled the capacity of the clerical staff and, once installed, the working costs are less than with ordinary book-keeping methods. In every way it has justified its introduction. Calculating machines have been installed in all the time-keeping and stores offices with most satisfactory results. One final advantage the card system possesses, the entire cost keeping and accountability cards are immediately intelligible to a layman. The system makes men accountants in spite of themselves.

The members of the staff were nearly all trained at the mine, and most all the shift bosses and foremen started work as miners or laborers. There is a good technical school in the town, and the management insist that all youths employed at the mine take certain courses and obtain certificates for attendance at the school.

At a mine, such as this, remote from other mining centers and for many years the only mine of importance in Central Queensland it might be expected that the staff would tend to become somewhat self-centered. In Kalgoorlie and Broken Hill there is a very notable absence of that knowledge of contemporary mining in other fields which is so essential for progress, and one might even go so far as to accuse those fields of something approaching to parochialism. But, on the contrary, the officers of the Mount Morgan mine are free from any suspicion of being self-centered. For many years Captain Richard has encouraged the staff to keep abreast with modern work and an extremely up-to-date technical library and reading room has been provided. All the senior members of the staff have visited the leading mines of Australia or America during their periods of leave. Above all, every inducement has been given to every officer to think for himself, and not to rely entirely on precedent.

In this brief sketch of the works and system at "the Mount" I have paid the highest tribute that is possible to the man under whose control the whole plant and system has been built up, Captain G. A. Richard, the general manager of the company. I wish to acknowledge my thanks to the management for the kindness extended to me during my visit and for the plans and photographs which were prepared for my articles.

Lowering a Large Pump Into a Mine

By GEORGE J. YOUNG*

The handling of heavy machinery in the limited space of a mining shaft is a matter of interest to engineers. Recently a large Knowles duplex, high-speed, motor-driven pump was erected on the 2,475-ft. station of the Ward shaft at Virginia City, Nev. This pump was constructed so that the largest piece would pass a 4x5-ft. compartment. The engine frame and main journals were constructed in a single piece, and this constituted the largest and heaviest part of the pump. The approximate weight of the piece, stripped and ready for lowering, was seven tons. Two of these pieces were to be lowered through a compartment 4 ft. 1 in. between guides and 5 ft. 6 in. wide. The hoisting engine in use, a light, steam-driven, direct-connected, double-reel hoist, was found to be inadequate, and a double-reel, gear-driven hoist with a single engine, having a 24 $\frac{1}{2}$ x30-in. cylinder, was constructed for the special purpose of lowering the pumping machinery. This engine and parts of the hoist were taken from the Combination shaft and the necessary additional parts constructed. The hoist was erected while the foundations for the pump were being laid.

The gross dimensions of the pump-engine frame were: Width, 4 ft. 4 in.; height, 3 ft. 10 in.; and length, 10 ft. 10 in. The guides in the south compartment were tested and set back where insufficient clearance was found. By Aug. 6 everything was in readiness to lower the first piece. This was moved by rollers and block and tackle to a position close to the compartment and between the shaft and the hoist. It was then turned over on its side and the lifting tackle adjusted. A short 10x12-in. timber, protected on both sides by $\frac{3}{4}$ x8-in. iron plates, was placed between the crosshead guides, and a $\frac{3}{8}$ -in. chain passed around it and through a gathering ring. Two $\frac{3}{4}$ -in. chains were attached through U-bolts passing through lugs on the base of the casting and then passed through the gathering ring. All chain ends were made fast with pins and links. The gathering ring was made fast to the cable-attachment pin, as shown in Fig. 1. The piece was then lifted and swung into position over the compartment. Bars were used to force it into approximate position between the guides, since the length of the chains would not permit the piece to assume a vertical position. It was next lowered onto a greased plate supported upon two 12x12-in. timbers placed across the compartment. Hydraulic jacks were then used to place it in exact position. The chains were next adjusted

by the U-bolts until, by trial, the piece swung vertically. The guide shoe was bolted in position and a 4x6-in. strut wedged between the free end of the shoe and the upper timber. Two lanterns were suspended from the shoe, and, with two

to 8 ft. The side clearance was 1 $\frac{1}{2}$ in. on each side.

The proposed method of handling was to lower the piece until it just cleared the planks and then by the aid of a chain block to swing the lower end into the sta-

THE METHOD OF LOWERING THE PUMP-FRAME IN THE SHAFT

men riding, the piece was lowered to the station.

METHOD OF HANDLING THE FRAME

The conditions at the 2,475-ft. station are shown by Figs. 4, 5, 6 and 7. The position of the wall plate at the station gave a clearance of 8 ft. 10 in. Two 6x12-in. planks on 4-in. rollers were placed across the compartment reducing the clearance

to 7 $\frac{1}{2}$ ft. A 7-ton weight on the end of 7 $\frac{1}{2}$ tons of steel cable and controlled by a single engine at the surface would hardly admit of nice adjustment of position, and in consequence the greater part of the weight was thrown upon the planks. An attempt to swing the lower end caused the planks to slip off the edge of the opposite wall plate and the piece to assume the position shown in Fig. 5. Two chain

*Professor of mining and metallurgy, Mac Kay Mining School, University of Nevada, Reno, Nevada.

blocks and a pulley tackle were required to partly lift and partly swing the piece into the position shown in Fig. 6. At this point the chain blocks and rope tackle were adjusted, as shown in Fig. 6. Then, by simultaneously pulling on all three blocks and lowering with the main cable

lower the piece 2475 ft. required 38 min., with two men at the hoist and two men riding; to land the piece at the station required nine men and a foreman $3\frac{1}{2}$ hours; to move from station to pump chamber required five men 2 hours. The total time required: Shaftmen, 82 man-hours; enginemen, 16 man-hours; or a total of 98 man-hours. With wages at the prevailing rate of \$4 per eight-hour shift and \$6 for foreman, the labor cost for lowering amounted to \$55. A counterbalance was used in lowering and consisted of the cage and loaded ore car in the adjoining compartment.

I wish to acknowledge the courtesy of Leon Hall and Superintendent McCormick in permitting me to be present and to take the above notes.

Calumet & Arizona Mining Company

The report of the Calumet & Arizona Mining Company, March 20, 1909, shows that for the year ending Dec. 31, 1908, the production of refined copper was 28,048,000 lb. In addition to this there was produced \$234,358 in gold and silver. The average price received for the refined copper delivered in 1908 was 12.948c. per lb. During the year \$800,000 in dividends were paid. The average number of men employed at the mines was 567. The number employed at the smelter was 484.

MINE

The policy of the management has been to treat as low a grade of ore as can be handled at a reasonable profit. This has resulted in a somewhat lower production for the year, but at a satisfactory cost. The market and industrial conditions have not been such as to justify any attempt to increase the production, and it is believed that the ultimate profit to the stockholders will be increased by the conservation of the ores.

The company still holds options upon claims amounting in all to \$530,000, payments of which are spread over the next 12 months. The amount expended in developing lands under option in 1908 was \$274,721, and for payments on options \$99,000. Development work done during the year at the Oliver, Irish Mag and Wagner shafts was as follows: Drifts, 18,444 ft.; raises, 2072; sinking, 135; total, 20,680 feet.

The company has options on 23 claims in the Courtland district. During the year 530 ft. of development work were done, 317 ft. of which were on the Germania No. 1 claim. The principal development, and that which resulted in showing the most ore has been from the 260-ft. level of this shaft. On this same claim a diamond-drill hole was put down to the depth of 1007 feet.

SMELTER PLANT

During the year a new converter stack was erected, using the material from the former 150x5-ft. boiler stack. A new dust flue leading from the converters to the stack was installed, and all of the converter stands were moved to the south side of the converter room. One new converter stand was added. This change was necessary to make room for the construction of a new furnace and the lengthening out of some of the old furnaces.

A new 25-ft. by 44-in. furnace was built, which has a nominal capacity of 500 tons per day, but which has averaged 557 tons per day since it was put in operation. The operation of this furnace has proved satisfactory and has effected material economy.

During the latter part of the year one of the old furnaces was rebuilt, making it the same size as the new one.

ASSETS AND LIABILITIES

The balance sheet Dec. 31, 1908, compares with 1907 as follows:

ASSETS.		1907.	1908.
Cash and copper on hand	\$1,240,474	\$1,230,783	
Ore in stock	46,060	87,310	
Supplies on hand	694,560	470,980	
Accounts receivable	380,141	336,914	
Notes receivable	917,245	1,382,055	
Stock in other companies	105,250	167,500	
Total	\$3,883,732	\$3,675,530	
LIABILITIES.		1907.	1908.
Accounts payable	\$277,908	\$252,280	
Excess of assets	\$3,105,823	\$3,423,270	

Operating expenses at the mine and smelter were \$2,089,158; construction, \$158,107. General expenses, including salaries, freights, refining and marketing, \$523,504.

The *Cleveland Marine Review* says that the first shipment of Lake Superior iron ore was made in 1852, and regular commercial shipments began in 1856. In that year there were brought down 11,597 tons; in 1857, 26,184 tons; in 1858, 31,035; in 1859, 65,679 tons; in 1860, 116,998 tons; in 1861, 45,430 tons; in 1862, 115,721 tons; in 1863, 185,257 tons; in 1864, 235,123 tons; in 1865, 195,256 tons; in 1866, 296,872 tons, and in 1867, 469,320 tons. From these figures can be seen the state of increase in shipments in each year. Coming on down to the year 1872, was a period of 18 years in which the iron ore business had slowly grown in volume, until the total number of tons brought down that year was 948,553. In 1907, the year of largest shipments, the total was 42,266,668 tons.

A discovery of tin is reported (*So. African Min. Journ.*, Jan. 23, 1909) on the Umfusi river, Melmoth. The pegmatite formation carrying the tin is 30 ft. in width and has been traced for several miles.

THE METHOD OF LANDING THE PUMP-FRAME AT THE STATION

at the same time, the piece was landed upon the floor of the station, as shown in Fig. 7. It was then blocked up and by means of rollers and jack-screws moved into position to be handled by the 8-ton crane of the pump chamber.

The cost of lowering this piece of machinery and the time consumed are shown by the following: To place engine frame in position ready for lowering required nine men and a foreman, $3\frac{1}{4}$ hours; to

Copper Mining in New Jersey

By HENRY B. KÜMMEL*

Many attempts to mine copper have been made in New Jersey, but so far they have been economically unsuccessful. The most persistent attempt, and one which best promises success, is that of the company operating the mines along the base of First mountain, three miles north of Somerville.¹ Here underground workings, comprising several thousand feet of drifts and tunnels, demonstrate the presence of a very considerable body of low-grade ore. Beyond the first 600 ft. the ore is practically all native copper. Numerous side drifts show the continuation of the same kind of ore beyond the line of the main slope, which has a length of about 1400 ft. on a 10-deg. dip. Many openings for several miles along the face of the mountain at the same geological horizon demonstrate the occurrence of ore at these several points similar to that found in the shallower workings at the main mine. There are many facts, therefore, to warrant the conclusion that the ore can reasonably be expected to continue beyond the areas in which it has been actually revealed by the workings. There is nothing in the geologic structure, so far as known, or in the theories regarding the origin of the ore, which is opposed to the supposition that it extends far beyond its observed limits. Although its occurrence over wide areas beyond the actual workings has not been established by actual development, nevertheless from a geological point of view the inference that there is a large amount of ore available and that the present workings could, in all probability, be very considerably enlarged without reaching its limits, is a safe one.

The ore occurs chiefly in a sheet of altered shale (1 to 3 ft. thick) immediately beneath a thick sheet of trap rock, the lower few inches of which is also frequently mineralized. The trap sheet and underlying shales have a gentle dip to the northeastward. The ore can be easily undercut by the removal of the underlying soft red shale and then shot down in large masses. Most of the shale can be left in the mine to fill work-out chambers. The firm trap sheet affords a solid roof, which needs no timbering. The ore can be blocked out by slopes and gangways, as is done in coal mines where the beds are horizontal or nearly so, so that many feet of working face can be readily obtained. Under these conditions mining costs ought to be low.

The copper occurs native in thin sheets, nuggets, flakes and minute particles irregularly diffused through the ore. Owing to its irregular distribution, the per-

centage of copper cannot be accurately determined by any system of sampling. Such results as have been obtained have led to the belief that it would carry 2 per cent. copper. Accurate determinations made after careful mill runs on quantities of ore from different parts of the mine may show a somewhat lower percentage.

Since the ore is native copper, the problem of its successful working reduces itself chiefly to one of economic and effective concentration. The old experimental mill has recently been entirely rebuilt and enlarged to a daily capacity of 350 tons. Concentration is effected by means of jigs and Wilfley tables; five of the former and three of the latter now being used. After

in power and equipment necessary to these changes, the mine has recently been equipped with an electric-lighting circuit.

For the first time conditions seem to be favorable for a thorough test of these New Jersey copper ores, and there is apparently good reason for hoping that the test will be economically successful. Credit is certainly due to the owners of this mine for their perseverance in the face of many disappointments. If the mill runs demonstrate that the ore averages 1½ per cent. of copper, or better, and if the great body of ore which it seems reasonable to infer exists here, shall be proved and its grade established by actual exploration, it would seem as if efficient management only was necessary in order to put this mine on a paying basis.

MERRILL CLASSIFIER

The Merrill Classifier

Charles W. Merrill describes (U. S. Patent 907,387, Dec. 22, 1908) an improvement on the forms of classifier previously patented by him (U. S. Patent 728,487, May 19, 1903). The classifier, one form of which is shown in the accompanying illustration, has either an inverted cone or pyramid-shaped receiver, with comparatively steep sides, the latter construction being adopted to reduce the velocity of the ascending pulp and promote the gradual descent of the heaviest particles of the pulp. An upward feed is used and the casting at the truncated apex provides not only the inlet or feed pipe, but also a pipe for wash water.

In describing his patents Mr. Merrill points out that in practice there are many classifiers provided with a downward feed, and that the overflow of particles from such classifiers have to make a complete turn in their direction before they can be overflowed. While such classifiers make a rough separation of fine slimes and coarse sands, the construction is not well adapted where a close separation between fairly heavy or coarse material and the very coarsest or heaviest material, such as concentrates, is to be effected. The patent letter states that "if an upward feed be substituted for the downward feed and the classifier provided with an outlet space adjacent thereto and preferably surrounding same but without the zone of the feed, it is possible to separate the concentrates or heaviest particles and overflow not merely the slimes, but also comparatively coarse sand, for the reason that there is no change of direction involved in the upward flow," as there is in the case of the downward feed.

The production of pig iron in the United States in 1908 required the handling of approximately 56,000,000 tons of raw material—ore, fuel and flux. A considerable part of the ore used was carried over 1000 miles

*State geologist, Trenton, N. J.

¹Annual reports of the State geologist of New Jersey for 1902, p. 129, 1906, p. 145.

breaking, the ore is hand-cobbed as it passes along a belt elevator, the best material going directly to the smelter. Of the remainder, that under 1 in. goes to the first jig, while the coarser material is re-crushed. The second and succeeding jigs receive successively finer material, the tailings from each being re-crushed before going to the next. The tailings from the fifth jig are classified before going to the Wilfley tables, so that each table deals with material of a different size. From 12 to 20 tons of ore are by these means reduced to one ton of concentrates. It is stated by the management that experimental runs made during the latter part of 1908 show that the low-grade concentrates carry from 6 to 10 per cent. of copper, that the high-grade concentrates reach 60 per cent., and that the final tailings contain not more than 0.1 per cent. of copper. A small reverberatory furnace has been completed, but it is not in operation. In addition to the improvements

The Present Status of the Tariff Question

The passage of the Payne Bill by the House, and the introduction of the amendments of the finance committee of the Senate enable us to see more clearly what the enactment is likely to be. Even after the bill now before Congress becomes a law, no one can say with absolute precision what it will accomplish. As usual, there will be many matters for the courts to decide. A good deal will depend, moreover, upon the nature of the administrative law. Finally, after all is said and done, it will remain for time to tell what will be the effect upon industry. Mr. Payne and Senator Aldrich with their comparatively few associates, who have been really instrumental in framing the tariff legislation, do not possess the precision to name justly the rates upon thousands of substances, as to any one of which even the experts in that particular field will not agree. As matters stand, however, the position of the metals, in which the mining industry is particularly interested, is as follows:

Aluminum—Ingot will be dutiable at 7c. per lb., or 1c. less than at present. Inasmuch as the price in this country is now practically the European price, plus freight and duty, consumers will gain a trifle.

Antimony—The present duty of 3/4c. per lb., on the metal, which rate was retained by the House, has been increased to 1 1/2c. by the Senate. The latter also imposes a duty of 1c. per lb. on the antimony content of ore and matte, at present free and also free in the House bill. The effect of this will be to increase the price of antimony in the United States, which will be chiefly to the advantage of the producers of antimonial lead (which may be the "joker"). The gain will not be enough to help the domestic producers of antimony ore and the smelting interest will be at a little disadvantage as compared to now. The Senate amendment as to the antimony schedule shies into the ring a new subject of dispute, which the courts will doubtless be called upon to decide.

Iron and Steel—The Senate proposes to have a duty of 25c. per ton on iron ore, which the House put on the free list. Pig iron remains at \$2.50 per ton, but the rate on scrap is raised to the same figure as a substitute for the House proposal of

50c. per ton. On bar iron, blooms, billets, etc., the Senate has made a further reduction; on beams, girders, etc., an increase. The duty on iron ore penalizes by just so much the manufacturers on the Atlantic seaboard who obtain supplies from Cuba, etc., without being of particular advantage to any of the American miners. The iron and steel industry can easily stand all of the reductions that have been made, the chief effect of which, as we have remarked before, will be to restrain an excessive rise of prices at a boom period.

Lead—The Senate has restored the rate on pig lead to the present figure. The House had maintained the rate on lead ore, but had reduced that on pig lead. This would have continued to deprive the smelters of ability to obtain foreign raw material, but would have advantaged consumers a little by preventing excessive rises in the price for the metal. In other words the average over a series of years would probably have been a little less. The leaving of this metal in *statu quo* will please both miners and smelters.

Quicksilver—This remains unchanged at 7c. per lb.

Tin—This remains on the free list.

Zinc—The Senate leaves the House proposal unchanged. The rates as to this metal have been sadly bungled, and serious industrial disturbance is inevitable. In deference to the wishes of the miners, who desire to obtain a higher price for their ore, a tariff of 1c. per lb. on the zinc contained in imported ore (now duty-free) has been imposed, but the rate on spelter has been reduced to 1c. per lb. and on sheet zinc to 1 1/4c. per lb. The differential between spelter and sheet zinc is less than the cost of rolling. The rate on zinc in ore is relatively higher than on the metal, because the smelter has to pay on the 15 to 20 per cent. that he loses in the process (unless the administrative law shall make allowance for this) besides paying on the lead in such ore which he may not recover at all. The effect of this will be to exclude largely the foreign ore, create a scarcity in the supply for our smelters, and boost the prices of both ore and spelter. The latter will be limited to the point at which it will be profitable to import spelter. There will be even more danger of imports of sheet zinc. The manufacturers of sheet zinc will, moreover, feel more keenly the competition of substitutes. The rather large quantity of

cross that is exported will doubtless remain in this country for smelting. The upset in conditions will be so complete that it is difficult to predict how the industry will readjust itself. It is even conceivable that the change will not work out to any great advantage to the operators in the Joplin district. Under existing conditions 5.40, New York, or 5.25, St. Louis, may be considered a normal price for spelter, at which the base price for ore at Joplin would normally be about \$39. At 5.50-5.35 ore would be about \$40. At that point, according to the tacit understanding, the wages of miners increase to per cent., which adds about \$2 to the cost of a ton of concentrates, so the price for spelter must rise above 5.70-5.55 before the operator begins to reap any further advantage, but long before that the European smelters may be delivering spelter in the Eastern market. Anyway it is certain that our smelters are confronted by a calamitous prospect. As between miners and smelters the advantage in the market ordinarily is sometimes one way, sometimes the other, but in the long run their interests are the same, and what hurts one is apt to hurt the other.

The Copper Statistics

The statistics for March, reported on the 12th inst., together with those for previous months, are as follows:

	March.	February.	January.
Production.....	117,058,661	103,700,817	112,135,200
Deliveries.....	108,063,007	74,546,614	90,362,421
Balance.....	8,995,654	29,154,203	21,772,779
Prov. sur.....	173,284,248	144,130,945	122,357,366
Surplus.....	182,279,902	173,284,248	144,130,045

The deliveries include the copper sold for both domestic consumption and for export. Deducting the exports gives the following:

	March.	February.	January.
Deliveries.....	108,063,000	74,546,000	90,362,000
Exports.....	46,646,760	31,104,040	42,985,600
Difference.....	61,417,237	43,441,974	47,376,821

It appears from the above that the deliveries for domestic consumption increased 18,000,000 lb. in March, but any such inference would be obviously incorrect inasmuch as it would indicate a consumption in excess of that of 1906, when it was 608,570,330, or about 55,000,000 per month. The explanation is, of course, that some copper shipped from the refineries for export had not been entered in the export statistics, being either on lighters or on the docks, etc., while perhaps some manufacturers, buying cheap metal,

took into their yards something in excess of their requirements. However, there is no question that the statistics indicate a healthy domestic consumption and reveal a turn of the tide in that respect, especially when we recollect the substantial buying that took place in March. Exports also appear to be rising to nearly the normal rate.

The disquieting feature is the continuing increase in production. So long as this goes on at undiminished rate we can hardly expect a higher level of prices (of course, disregarding slight and temporary fluctuations). The production in March was 3,776,000 lb. per day, compared to 3,703,000 in February and 3,617,265 in January. But it is worth while to point out that in March the refineries were still working on blister copper produced in December, when there was general ignorance as to the real situation in copper, and producers were operating at full capacity, believing that the prospect was for the maintenance of the rather fair price that existed then, if not for some improvement. Since then there has been some material curtailment by the closing of several high-cost mines, while only Ely, Cananea and Cerro de Paseo have been increasing materially. It would not be surprising if the production of refined copper should show a decrease in April and if the accumulated stock would begin to wane.

The Two Leading Steel Producer

The make of pig iron and steel in Germany, like that in the United States, reached its maximum point in 1907. From that point there was a considerable recession in both countries during 1908, though the drop in German production was moderate in degree. The total output of pig iron and steel in both countries for two years past is given below; American figures being in long tons, and German in metric tons:

	United States		Germany	
	1907	1908	1907	1908
Pig Iron.....	25,781,361	15,936,018	13,015,760	11,813,611
Steel.....	23,362,694	14,007,627	12,061,632	11,186,379
Prop. steel to iron, 90.6	87.9	87.9	92.6	94.7

In the United States the decrease in pig iron last year was 9,845,343 tons, or 38.1 per cent.; in steel, 9,355,067 tons, or 40 per cent. In Germany the changes were much less marked, the decrease in pig iron having been 1,232,240 tons, or 9.4 per cent.; and in steel, 877,253 tons, or 7.8 per cent.

These decreases are large for Germany, where the iron and steel production had increased steadily for a series of years; and where the changes in either direction are always much slower and less marked than in this country. The extent of the difference is shown by the statement that the German pig-iron production in 1907 was only 50.6 per cent. of that in the United States; in 1908 it equaled 74.1 per cent. In both countries by far the larger part of the pig iron made is converted into steel, from which most of the finished products are manufactured.

The details of the steel production of the two countries in 1908 were as follows:

	United States		Germany	
	Tons.	Per Ct.	Tons.	Per Ct.
Acid Converter..	6,116,755	43.6	374,100	3.3
Basic Converter.....	...	...	6,510,754	58.2
Total Converter	6,116,755	43.6	6,884,851	61.6
Acid open-hearth	196,304	5.0	224,211	2.0
Basic open-hearth	7,084,568	50.6	3,969,595	35.5
Total Basic.....	7,780,872	55.6	4,193,806	37.5
Crucible and Spec.	110,000	0.8	107,719	1.0
Total.....	14,007,627	100.0	11,186,379	100.0

Of the steel made in the United States 49.4 per cent. was acid and 50.6 basic; the proportions in Germany being 6.3 per cent. acid and 93.7 basic. The basic converter, in which more than half the German steel is made, is not used in the United States at all. It is to be noted that the German report includes, for the first time, electric steel; the quantity made in the electric furnace having been 19,536 tons.

The use of the various processes is, of course, largely determined by the character of the supplies of raw material. The German industry is based upon ores which are for the most part too high in phosphorus to make pig iron amenable to conversion by the acid process. In the United States there is a large supply of ores which are below the so-called bessemer limit in phosphorus, and will, therefore, make pig iron suited for the acid converter. Nevertheless, the reserves of low-phosphorus ores are smaller and are being drawn upon more heavily than those of basic ores; for which reason the basic open-hearth process in the United States is the branch of the steel industry which has grown most rapidly in recent years, and is sure to grow most in the future.

REPORTS ARE now becoming more frequent of copper mines that are being closed to make necessary repairs, or are letting a part of their furnaces go out of blast "while copper continues so low," etc.

California Oil Companies

The Anthracite Situation

For the last two years the production of the hydrocarbons, including petroleum and asphaltum, in California, has been of greater value than the gold output of the State. In 1907, according to State statistics the combined value of the hydrocarbons and gases produced reached \$18,029,937 against \$16,727,928 for gold, and the 1908 oil output is estimated as valued at \$23,000,000.

The accompanying table published in the San Francisco Call of April 2, 1908, shows

The anthracite labor situation is still entirely uncertain. At the conference which began April 7 the operators made a final offer to renew the old contract for three years. In reply the miners submitted a counter-proposition which carries with it moderate requests. One was that in all instances where wages were reduced during the last three years for any cause, the operators should restore them to comply with the scale fixed by the Strike Commission; the other was a stipulation that

operators present also. An official statement of the proceedings says: "The action of the operators' committee of seven in the conference with the mine-workers' representatives was unanimously approved. It was not decided to reduce the wages of the mine workers at the present time. A committee of 11 was appointed and instructed to formulate a policy to be followed by the operators. This committee will report at another meeting on April 22."

The special committee is made up as follows: W. A. Lathrop, Lehigh Coal and Navigation Company; W. J. Richardson, Philadelphia & Reading Coal Company; S. D. Warriner, Lehigh Valley Coal Company; R. A. Phillips, Delaware, Lackawanna & Western; Robert Quin, Susquehanna Coal Company; C. C. Ross, Delaware & Hudson; W. A. May, Pennsylvania Coal Company, and the following individual operators: W. L. Connell, Frank Borden, T. M. Righter, and John R. Bryden.

Meantime work continues at the mines as usual, neither side, apparently, wishing to take the responsibility of a stoppage of production. In this respect the situation is altogether an unusual one.

Total dividend paid to date. \$19,154,058 89

Total dividends paid by the above companies for March, 1909, \$402,509.21.

Coalinga Pacific paid two dividends in March, dividend No. 10 of 10c per share on March 1 and dividend No. 11 as above noted. Lucile paid dividends No. 8 and No. 9, of 10c each, on March 15.

the dividends paid (amounting in all to \$19,154,058) by the active listed oil companies up to April 1, 1907.

According to *Echo des Mines*, a company styled the Banque de Radium has been founded by Henri Farjas for the purpose of purchase and sale of radium salts. The capital is 1,000,000 francs, to be subscribed entirely in cash. Mr. Farjas has promised to supply the company within a period of two years, dating from the day of its formation, with a minimum of three grams of pure radium bromide at the price of 400,000 francs per gram. During the first year he will deliver one gram, and in the next two grams. In remuneration for this, 3000 beneficiary shares, giving the right to 15 per cent. of the profits, are presented to Mr. Farjas.

any miner who is discharged shall have the right to appeal, and if it is shown, after an investigation, that the dismissal was not justified, he shall be reinstated. The third request was in the nature of a concession on the part of the miners. In it they gave up their demand for recognition of the United Mine Workers of America, and substituted the suggestion that the operators sign the new contract with the delegates as representatives of the "United Mine Workers of Anthracite." This counter-proposition was rejected and the conference adjourned without result. Another general convention of the mine workers in the anthracite field is to be called by the committee.

A general conference of operators was held in New York April 12, at which all the large companies were represented, and there was a large number of individual

The suggested removal, by both Canada and the United States, of the existing duty on coal interests western Canadian coal-mine operators chiefly in regard to the latter, for there is little present probability of coal from either Washington or Oregon coming into competition in either British Columbia or Alberta with that produced from mines in those provinces. From a Dominion point of view, though the question presents serious difficulties, for, while it would benefit both the coal producers of western Canada, who already have a market for much of their product in the northwestern States and Alaska, and the consumers of Ontario, who buy from the States, to have reciprocity in connection with the sale and purchase of coal, coal-mine owners in eastern Canada would find the competition of the eastern States very harmful to their trade interests of the former. It is, therefore, thought by many in the West that, notwithstanding the considerable increase in the export of coal from western Alberta and British Columbia that would result were the United States duty removed, the eastern Canadian interests that would be disadvantageously affected by the removal of the corresponding duty on coal from other countries brought into Canada are so important that the Dominion government will be slow to take action prejudicial to the coal trade of the eastern maritime provinces of Canada.

Canadian Duties on Coal

SPECIAL CORRESPONDENCE

Questions and Answers

Inquiries for information are answered in this department as promptly as possible, but more or less delay is often unavoidable. Many inquiries involve a good deal of investigation and these can be answered only when the general interest in the subject is conceived to justify the expenditure of the time required. Correspondents should refrain from asking for advice that ought to be obtained by professional consultation with an engineer. We will not answer questions pertaining to the value of specific mining enterprises. Inquiries should be framed concisely.

MANUFACTURE OF BLASTING POWDER

I shall be obliged if the JOURNAL will inform me respecting the manufacture of blasting powder by coal miners. I understand that in some parts of America the coal miners themselves manufacture blasting powder to some extent. Some fellow will come along with a recipe which he sells, usually at about \$1. He assures the miners that they can make their own powder very much cheaper than they can buy it. Accordingly they begin the manufacturing process, ordinarily using the kitchen stove to prepare their concentrated sugar water, which serves as a binder to hold together the other ingredients.

E. H.

We are unaware that this practice is indulged in. Perhaps some of our readers can throw light upon the subject. We surmise that the fakirs who sell such recipes give simply a formula for mixing sugar and chlorate of potassium. It is dangerous for the ignorant to make any experiment of this kind.

IRON ORE RESERVES OF THE WORLD

I have here an extract of a report by Professor Tornebohn for the Swedish government, with relation to the available supply of iron ore of various countries. The figures shown in Professor Tornebohn's report are as follows:

United States	1,100,000,000	tons
Great Britain	1,000,000,000	"
Germany	2,200,000,000	"
Spain	500,000,000	"
Russia	1,500,000,000	"
France	1,500,000,000	"
Sweden	1,000,000,000	"
Austria Hungary, etc	1,200,000,000	"

I have consulted all available records here, such as libraries, etc., with a view of checking or confirming these figures in connection with certain data which I am preparing, but have not been successful in securing any data that gives the iron-ore resources or reserves of the above countries. I am, therefore, writing to you to see if you can advise me of any publication which will give this information. I would like to add Mexico to the list. I am very anxious to secure the data for Mexico as the iron-ore resources of that country are not shown in the abstract of the report above given.

C. J. H.

The question of iron-ore supplies is a very large one, and cannot be answered

readily with any approach to definite figures. Even with regard to ore deposits more or less definitely proved, the opinions of experts differ widely. With those known to exist, but not explored nor worked, the quantity is a matter of conjecture. Moreover, there are known deposits not considered available under present conditions, which may be utilized hereafter when proper methods of concentration, or of freeing the ore from impurities are devised. It would not be safe to neglect these in any estimate of the future of the iron industry in the various countries.

As to the various European countries, where iron ores have been mined for many years and where the deposits are well known and have been more or less thoroughly explored, Professor Tornebohn's estimates appear to be fairly correct. The possibility of further discoveries is comparatively small in view of the thorough prospecting which has been done. The only new finds of iron ore of importance in Europe in the last 10 years were those in Briey basin in France, which increased the known ore reserves of that country by nearly 50 per cent.

As to the United States, however, the figures are manifestly too low, and it looks as if the author had taken as a total some current estimates of the ore reserves of the Lake Superior region, made a year or two ago, which placed the total between 1,000,000,000 and 1,100,000,000 tons. This estimate has since been extended by explorations on the western Mesabi and by discoveries of ore at greater depths on the Gogebic and Menominee ranges in the Lake region. Moreover, the inclusion of lower-grade ores, down to 40 and 35 per cent. iron, would increase the known reserves by at least one-third. Besides the Lake reserves, the known iron-ore deposits in South are conservatively estimated at 700,000,000 tons. In addition to these there are deposits in the East, as in New York where the Adirondack region has large reserves, which will be increased when means are devised of utilizing the titaniferous ores not now classed as available. Other large ore deposits known to exist, but not now available on account of their situation and lack of transportation, are in Virginia and West Virginia; in northern and western Texas; in southern Utah, and in Wyoming. It is hardly going too far to say that the Tornebohn estimate for the United States should be multiplied by four, if not by five.

As to Mexico, to which the question applies especially, the only large deposit of iron ore worked so far is in Durango; but others have been discovered, though not worked nor explored enough yet to give any reliable estimate of their probable contents. An estimate of the Mexican ore reserves at present would be very largely conjectural.

Canada is also omitted in the table. But Canada already mines a good deal of iron ore in the Lake Superior region, at Moose mountain and in other sections of northern and western Ontario, and in Nova Scotia. In all these sections there are large reserves, and others remain to be developed in Ontario and in British Columbia. Outside of these there is undoubtedly iron-bearing territory as yet little explored, but having many indications of possible value.

Some deposits now worked which Professor Tornebohn does not include are those of Algeria and Tunis in northern Africa, from which considerable exports are made to France and England; and those of Cuba, which are extensive, and which supply some furnaces in the United States. Others known to exist, but not explored to any extent are on the Orinoco in Brazil; in Venezuela; in Peru and possibly in Argentina.

It is apparent that the iron-ore resources of the future already definitely known are very much larger than the Swedish authority would lead us to suppose. Beyond this there are possibilities, above outlined, which may extend the supply for many generations. There is no need of anticipating the failure of the world's supply of iron and steel because of a failure of the raw material.

The data on this subject must be sought in many reports and other publications. There is no one publication in which they can be found.

In a report on the metallurgical plants of China, M. de la Batie, French Consul at Han-Kow, describes in *l'Echo des Mines* an ore-dressing plant at Wou-tchang. The mill was erected by a Swiss company, which transferred it to Carlowitz & Co., a German corporation, that has operated it since 1903. The plant has a complete equipment of crushing and concentrating machinery, with the necessary motive power, and a stone pier on the Yang-ste-kiang. Lead and zinc ores from Hunan and Kuei-teheu are treated, at the rate of about 12,000 tons per year. Ore containing 34 per cent. zinc is concentrated to 55 per cent., and lead ores with 42 to 45 per cent. metal are dressed to 78 per cent.; the concentrates are shipped to Europe.

It is announced that the asbestos deposits in the Urals, near the Bajenovo station on the Perm railway, are about to pass into the control of a German company, with headquarters at Ekaterinburg. The company has already secured the Poklefsky-Kozel mines and works and the Girard de Soukanton mines, the two leading producers in the district. The Korevo mines, according to *l'Echo des Mines*, are included in the negotiation. The asbestos resources of this district are said to be second only to those of Canada.

Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Tamping Shot Holes in Coal Mines

I have been reading carefully and with much interest the articles relating to tamping shot holes. There seems to be quite a divergence of opinion on this subject, and it is apparent that some recent writers have had little actual experience in tamping and firing shots. Some authorities contend that it is necessary to tamp the hole completely and tightly with some adhesive substance, such as damp fireclay, while other engineers are equally positive that just as good results can be obtained by partially filling the shot hole with slack or fine coal.

I have had 25 years practical experience at such work and have been a shot-firer for several years; in the performance of such duties it was necessary to tamp hundreds of holes. My observation leads me to believe that it is not so much a matter of how much or how little tamping is used, or the kind of stuff that is used for tamping, as it is in the preparation of the shot. Where the shot is well balanced and the hole is not drilled in the solid, making what is termed a "dead" hole, and the right amount of powder is used, one will get just as good results by using a few inches of tamping as if he tamped the hole tightly clear out to the mouth. Of course, where the antiquated style of using a needle and exploding the shot with a squib is in vogue, then the hole must be tamped completely and tightly so as to leave an orifice for the flame from the squib to reach the powder in the hole. But where fuse or a blasting barrel is used, no such precaution is necessary.

In driving headings or entries, it is common occurrence to encounter some very wet holes. In such cases I have made the cartridge as nearly water-proof as possible, inserted the blasting barrel, pushed the cartridge into the hole, run the tamper in on it, lighted the squib so that the shot would explode in a few seconds and got just as good results as if all the hole had been tamped tightly to the mouth.

AN ACTUAL CASE

One incident that happened in southern Illinois, where the coal was being shot off the solid, and where heavy charges of powder were required to dislodge it, proved to me conclusively that tamping has little to do with it. The coal was scarcely 5 ft. thick. The hole was 4 in. in diameter, 8 ft. deep, and was fully 5 ft. on the solid, but was well balanced, being about the

same thickness at the toe as at the heel. The miner had just inserted the cartridge, which contained 8 lb. of standard grade black powder. Just as he had pushed the cartridge to the back of the hole, using a small iron scraper for that purpose, he raised his light a little too high and ignited a small pocket of gas just over the hole. He became alarmed and immediately ran away fearing the shot would explode and kill him.

Now there was not a particle of tamping on the shot, not even the scraper, for he jerked it out of the hole in his haste to get away. The flame from the gas ignited the fuse at the outer end, which burned as usual and caused the shot to explode. I stood within 100 ft. of the shot when it exploded and was not harmed. After waiting until the smoke had cleared away, I returned to see what the effect had been, and was certainly surprised to see that the shot had done its work well, having dislodged the coal from one end of the hole to the other end. It made nice, chunky coal and laid it over in a pile. Since this occurrence I have been convinced that lots of tamping rammed in tightly is not necessary under proper conditions. Of course, I believe it is advisable to use some tamping in every hole.

JOHN E. WILLIAMS.

Springfield, Ill., March 25, 1909.

Tungsten and Vanadium

The article of Professor Baskerville on tungsten in the JOURNAL of Jan. 23, 1909, and that on vanadium in the issue of March 6 contained some errors, and there are also some omissions. In discussing tungsten, he fails to mention Boulder county, Colo., as a source of the ore. Hübnerite is not "abundant" in the mines at Osceola, Nev. On the contrary, the Osceola mines are of but little, if any, commercial value as a source of this metal; the orebodies have not been at all persistent. The district near Nederland, Boulder county, Colo., is admitted by all authorities to be the most important tungsten field that is known, not only as to extent, but also as to the richness and purity of the ore. Colorado is not worth mentioning as a source of scheelite.

With respect to vanadium, Professor Baskerville makes no mention of the most important ore of that metal, viz., "patronite" (vanadium sulphide). This ore is found in Peru and is unquestionably the most important source of vanadium so far discovered. Irrespective of the discovery

in Peru, roscoelite is not the most important vanadium mineral. The vanadate of lead found in Spain has been an important source of vanadium. The slag from the iron works at Creusot, France, was for many years one of the most important sources of vanadium.

Tungsten and vanadium are now two of the most important metals in the manufacture of "alloy steel" and the makers of that class of steel throughout the world are very much interested in these two metals and their occurrences. Tungsten gives hardness to steel, and also the peculiar property of cutting metals when the tool is at a "red heat." Tungsten steel is one of the poorest "shock" resisting steels known, but it has great crushing strength. When it comes to turning surfaces where the "cut" is interrupted, such as the teeth of a gear, tungsten steel has but little advantage over ordinary carbon tool steel.

A. H. HALE.

Denver, Colo., March 15, 1909

Suggestion for a Fuse Spitter

Different miners, and especially different mining districts, have different ways of spitting a round of fuses. When one miner is to spit, for example, 12 fuses, probably the best method in use is to hold the fuses in one hand between the fingers, in the order they are to "go," and run over them with a "spitter" (a short piece of notched fuse).

This method, like every other one I know of, has its drawbacks. If one fuse will not spit it will be necessary to stop and cut it again. This is difficult to do. Sometimes one fuse has been overlooked. It is not easy to find it after the rest have "gone," and when finally spit is liable to spoil the round by "going" out of its turn.

In spitting a round I like to have both hands available for an emergency, so have finally developed this system. I keep a clothespin in my pocket, and after splitting the fuses I put them into the clothespin in the reverse order in which they are to "go," i.e., so that the first to be spit can be pushed out if desired, the last one to be spit being in the crotch of the pin. With a "spitter" I run over the fuses in the order they are to "go." After they are all spit the clothespin is removed.

This method does away with all the disadvantages of other methods except one; that is, that the fuses must be held or tied in the pin until they are all spit, or they

will fall out. In a case where a dozen or more fuses must be spit in a wet place, and where they must be spit at the moment when the signal is given by other miners—which may be one or 20 minutes hence—this method works very well.

As stated, the difficulty is the tendency of the fuses to drop out unless held in place. To make a perfect device for this purpose, combined with a crimper and fuse cutter, would be a simple matter, and perhaps a profitable one. A pair of ordinary crimpers could have handles made of rigid metal such that when crossed they would have their inside faces parallel and just a little closer together than the thickness of the fuse.

By putting proper teeth on the inside faces of the handles and an easily closed and opened clasp, it would be possible to put a dozen or more fuses in this device, clamp it so as to hold them, and whenever desired, to split and spit them in their order, and then unclasp the crimper and release the fuses. A crimper made to hold the fuses for spitting would probably save many missed holes, or rounds spoiled by the holes going in the wrong order. This is offered as a suggestion for those who may be in a position to manufacture such a device.

ARTHUR O. CHRISTENSEN.

Dorchester, Colo., April 9, 1909.

Ammonia Cyanide Process

I note with interest S. E. Bretherton's letter on the "Extraction of Zinc from Mixed Ore," in the *JOURNAL* of March 27, 1909. The extraction of both zinc and copper with incidental precious metals from complex ores by means of ammonia-cyanide methods now promises to become of importance to the mining industry. Both myself and Mr. Ludlow have worked hard for many years to put the technical side of the process on a practical basis. Instead of the expensive potassium or sodium salt in my recent U. S. Pat. 911,254, cheap calcium cyanide dissolved in ammonia is to be used in the extraction of gold and silver when present with zinc or copper in an ore.

Calcium cyanide is prepared from the new and cheap product, calcium cyanamide, by exposing the latter at a red heat to generator gas or acetylene for several hours, or until the conversion of cyanamide into cyanide is complete.

In the *Electrochemical and Metallurgical Industry* of March, 1908, the ammonia-cyanide process, including the Mosher-Ludlow continuous boiling-out still was described in detail. The main value of ammonia in the extraction of zinc from ores is in its refining feature, a snow-white product consisting of almost pure zinc oxide being obtained from complex ores without difficulty.

D. MOSHER.

San Francisco, Cal., April 5, 1909.

Submarine Petroleum

In the *JOURNAL*, of Jan. 2, 1909, there was published a view of the Summerland oil wells, accompanied by the statement that, "as far as we know the situation of these wells is unique." I beg to call attention to the fact that at Zorritos, on the northern part of the coast of Peru, there are several wells on the beach and one in the sea at the end of a pier built to facilitate the drilling of the well.

Manila, P. I. GEORGE I. ADAMS.

Wallaroo & Moonta Costs

In the statistical number of the *JOURNAL*, Jan. 9, 1909, page 125, the cost of producing copper at the Wallaroo & Moonta mine has been inadvertently doubled owing to the actual total cost of \$261 having been inserted between "shipping and other charges," and the total cost per ton of fine copper has thus been made to read \$522. I regret the error in my manuscript and hasten to make this correction.

F. S. MANCE.

Sydney, N. S. W., Feb. 24, 1909.

A Volumetric Method for the Determination of Barium

A new volumetric method for the determination of barium (E. A. Hill and William A. H. Zink, in *Journal*, Am. Chem. Soc., Jan., 1909) depends upon the precipitation of the barium as iodate and upon the oxidizing action of this compound upon an iodide solution, with subsequent titration of the free iodine with sodium thiosulphate. A series of experiments showed that in a neutral or alkaline solution, with an excess of potassium iodate the precipitation is so complete that the filtrate shows no turbidity upon being warmed with sulphuric acid.

The properties of precipitated barium iodate are almost ideal for analytical work. It forms a white granular substance, settling quickly, leaving a perfectly clear liquid above. The precipitation is complete in five minutes, if the mixture is thoroughly stirred. The precipitate filters easily.

Since barium iodate is soluble in water, the critical point in the analysis of barium iodate is its treatment after filtration. A series of experiments showed that it could be washed with concentrated ammonia at least three times, and this followed by three to five washings with 95-per cent. alcohol without any appreciable loss.

The solutions required for the analysis are approximately one-sixth normal solution of potassium iodate and one-tenth normal sodium thiosulphate. The soluble

barium compound to be analyzed is taken in an amount that will contain about one gram of barium, rendered faintly alkaline by addition of ammonia.

Calculate amount of potassium iodate required, and then add about 25 c.c. in excess. The precipitate is then washed with concentrated ammonia and alcohol. Transfer to Erlenmeyer flask, add 50 c.c. 10-per cent. solution of potassium iodide, the iodate content of which is known. Add 10 c.c. concentrated hydrochloric acid, and allow to stand five minutes; wash down sides of flask, and titrate the free iodine with standardized thiosulphate solution, using starch as an indicator.

The method as given may be applied to solutions of barium as hydroxide, chloride, bromide, iodide, nitrate and acetate, or other soluble salt of an organic acid. Sodium salts may be present in any amount, and magnesium, ammonium, or potassium salts in amounts up to one-half gram, calculated as chlorides. Calcium and strontium must not be present.

An Unusual Pump Installation

A horizontal centrifugal pump, performing a somewhat unusual service, is used to withdraw the water from the hot well of a surface condenser against a vacuum of 28 in. on the suction side. This vacuum of 28 in. would be equivalent to a 32-ft. lift which would not be advisable for a pump of this small size if operating against this suction lift. That the pump operates successfully is due to the fact that it is placed lower than the hot well of the condenser and for this reason the water flows by gravity to the pump, notwithstanding that there is a vacuum on the surface.

The pump is a 3 in. class A, centrifugal type, manufactured by the Buffalo Steam Pump Company and is driven by a 10-h.p. 100-volt, vertical shaft Crocker-Wheeler motor operating at a speed of 1200 r.p.m. The pump has a normal capacity of 213 gal. per min. against a total head of 78 ft. including a discharge lift against which the pump handles the water.

A brass impeller machined all over is used in pumping this hot water. At the top of the main frame is mounted the motor which drives the vertical pump shaft by a flexible coupling. About midway of the main frame the removable thrust bearing housing is suspended from a heavy rib of the main frame. This pump is fitted with ball bearing type of thrust, and the stuffing box on the pump shaft bearing is sealed to the vacuum by water pressure obtained through a small pipe. Owing to the careful design and the machining of the pump runner, there is said to be little loss by slippage and a high combined efficiency.

illustrated. $6 \times 8\frac{3}{4}$ in.; cloth, \$3. New
York, 1909: John Wiley & Sons;
London, Chapman & Hall, Ltd.
- Contents: Qualitative tests for chro-
mium, vanadium, copper, titanium, nickel,
molybdenum and tungsten in steel. Analysis
of vanadium steel and ferro-vanadium.
Analysis of titanium steel and ferro-titan-
ium. Analysis of tungsten powders. Analy-
sis of tungsten steel and chrome tungsten
steel. Analysis low per cent. tungsten
steel. Analysis of molybdenum powders.
Analysis of tungsten-molybdenum steels.
Analysis of ferro-chrome, chrome ore
and carbonless chrome. Determination
of aluminum in steel. Determination of cop-
per in steel and pig iron. Separation of
nickel and copper from iron and vanadium
by potassium ferricyanide. Determination
of copper in metallic copper. Rapid de-
termination of nickel in the presence of
chromium, iron and manganese. Analysis
of ferro-manganese. Rapid volumetric
method for manganese in the presence of
iron, calcium and magnesium. Determina-
tion of carbon in iron and steel by direct
ignition with red lead or litharge. De-
termination of carbon in steel, ferro-al-
loys and plumbago by means of an elec-
tric combustion furnace. Also by gas
and blast. Carbon in steel by color. Phos-
phorus in steel, pig iron, bar iron and
wash metal. Sulphur in steel, bar iron,
pig iron and wash metal. Manganese in
special steels, bar iron and wash metal.
Silicon in iron and steel. Analysis of
graphite and graphite crucibles. The an-
nealing of plain and special steels. Per-
centage reduction of acids. A practical
automatic steam water still. A simple
laboratory method for making clay com-
bustion boats.

The Pittsburg Coal Company

This company owns and leases a large area of coal lands in the Pittsburg and Hocking valley districts, and is the largest miner and shipper of bituminous coal in those districts. It also controls the Monongahela River Consolidated Company, which operates most of the river mines in the Pittsburg district.

The capital stock is \$32,000,000 common and \$32,000,000 preferred. The debt includes \$20,602,000 first-mortgage bonds; \$1,423,451 bonds of subsidiary companies; \$1,799,572 mortgages and purchase money obligations. The depreciation reserve fund amounts to \$1,006,283; pension fund to \$86,243. Dividends on the preferred stock have accrued since March 1, 1905. Of the stock there are 49,282 shares preferred and 38,954 common held in the company's treasury. The net current assets, or working capital, amounted to \$3,355,561 at the close of the year.

A comparative income statement for two years is as follows:

	1907.	1908.	Changes.
Net earnings.....	\$5,731,983	\$3,924,921	D. \$2,707,062
Depreciated coal lands.....	\$ 725,937	\$ 564,062	D. \$ 161,875
Dopr. plant, etc.	964,809	952,346	D. 12,463
Bond interest.....	1,082,644	1,042,797	D. 39,847
Total charges.....	\$2,773,390	\$2,559,205	D. \$ 214,185
Net surplus.....	\$2,958,593	\$ 465,716	D. \$2,492,877
Special adjustments.....	59,001	433,284	I. 374,283
Balance.....	\$2,899,592	\$ 32,432	D. \$2,867,160
From previous year.....	4,089,211	6,988,803	I. 2,899,592
Total surplus.....	\$6,988,803	\$7,021,236	I. \$ 32,432

The net earnings are the results obtained after deducting all operating and general expenses and taxes.

The coal statement for two years is as follows:

	1907.	1908.	Changes
Pittsburg district.....	18,005,382	13,217,545	D. 4,787,837
Hocking district.....	1,348,112	1,064,586	D. 283,526
Total mined.....	19,353,494	14,282,131	D. 5,071,363
Coke made.....	458,933	55,099	D. 401,834

Coal mined includes coal used in making coke. The decrease in Pittsburg coal last year was 26.6 per cent.; in Hocking, 21; in total coal mined, 26; in coke, 88 per cent.

The coal-land statement for the year is as follows, in acres:

	Owned.	Leased.	Total.
Pittsburg District:			
Hold Jan. 1.....	185,838	23,917	209,856
Bought or leased.....	1,001	2	1,003
Mined out or sold.....	1,643	408	2,051
Hold Dec. 31.....	185,196	22,611	207,807
Hocking District:			
Hold Jan. 1.....	8,127	1,943	10,070
Bought or leased.....	87	—	87
Mined out.....	71	207	278
Hold Dec. 31.....	8,113	1,736	9,849
Total Dec. 31.....	193,309	24,347	217,656

Of the Pittsburg district lands 141,735 acres are on the Pittsburg vein and 43,461 on the Freepoint vein.

The report says, in part: "The total tonnage for 1908 was the lowest in the history of the company, excepting that for the year 1901; but maintenance of the

tonnage proportion of the company in former years, from the district, was preserved. Three mine plants were abandoned during the year, reducing the number of separate coal-mining plants to 76 owned and leased. Of this number 26 plants, or 34 per cent. of the whole, were idle throughout the year; the remaining 50 plants, by reason of loss in running time, due to delays at all of the plants, were reduced to an equivalent of 38 plants running full time throughout the year. The 76 coal-mining plants were used to the extent of but 49.41 per cent. of the full coal-mining capacity of the company, and 29.11 per cent. below such use for 1907. That the tonnage loss was but 26.2 per cent. below 1907 was due to better work on the part of labor and improved facilities at the plants worked.

"The company experienced unfavorable trade conditions practically throughout the year. The falling off in demand for coal, due to the general decline in business, which set in during the latter part of 1907, continued as to the general trade during the year, and still continues; and as to the Lake trade, the same cause was added to by an open winter. The unusually large dock stocks carried over from 1907, the heavy falling off in demand everywhere, better labor supply, and the great stimulus to coal production in other fields through release of railroad facilities from general business, were the main causes of the large decrease in tonnage.

"The average selling price of the product fell off 3.52c. and the cost of production increased 4.53c. per ton run-of-mine coal, compared with 1907. The coke ovens were practically idle during the year, and at a net loss. The decrease in selling value was due to a weakening in general market prices, brought about by the conditions of lessened demand and unusual competition, the latter chiefly from the more distant fields of cheaper production, and which had to be accepted to some extent; and the increase in cost was wholly due to the effect of so large a decrease in the output, as costs of labor and supplies, the condition of the plants and the efficiency of the organization in charge, would have held the total cost on at least the level of 1907, on the same tonnage.

"The suspension of dividends upon the preferred stock occurred as of March 1, 1905. The net earnings of the company since then have been \$6,242,001. This money has been used for the payment of:

Advance royalties.....	\$ 454,088
Bonds of subsidiary companies.....	339,242
Car trust notes.....	439,443
Monongahela River Consolidated preferred stock.....	1,496,229
Preferred and common stocks of this Co.	1,383,397
Property purchase money mortgages.....	322,956
Stocks and bonds of other companies.....	533,510
Dividend on preferred stock for Jan. and Feb., 1908.....	843,273
Deductions from 1908 earnings.....	197,312
Property and equipment purchases.....	115,588
Total.....	\$6,242,001

"The obligations as above discharged

were all incurred prior to 1905, and the paramount interest of the shareholders was regarded in meeting them. The payment of them has given additional value to the stock.

"The amount of taxes other than for local special improvements, for the year 1908, paid to the State of Pennsylvania, and to the different municipalities, was \$466,354, being about 13 per cent. of the gross, and more than the whole net earnings of the company. The results of the year show that of the cost of production nearly 70 per cent. was labor, 5 per cent. was the assumed value of the coal in place, and after the company had been cleared of all costs and charges, that there was an average net gain of 3 3/4c. per ton of run-of-mine coal mined and sold.

It would seem that State taxation should be more on a parity with corporations engaged in manufacturing, and whose capital and labor are thereby preferred; and that local taxes should be laid with more regard to the coal actually mined during the tax period, together with the value of the plants and equipments actually in use to produce the same, and as is done with others minerals.

"The Darr mine disaster of Dec. 19, 1907, cost the lives of 238 men, all there were in the mine at the time of the explosion. There are now pending 60 suits for damages. The cost of rescue work, interments and relief, amounting to \$82,407, has been charged to the personal injury fund; and the cost of restoration of the mine property, in the sum of \$60,866, has been charged to the depreciation reserve fund. The heavy money loss is of little note as against the loss of life, which occurred after all the safety provisions believed possible, and in addition to those under law and custom of the district, had been taken by the operating department officers."

Wages at Broken Hill

In the Broken Hill labor dispute, Justice Higgins, the arbitrator, has fixed the rate of wages for unskilled labor at Broken Hill and Port Pirie at 8s. 7 1/2d. and 8s. 3d. a day, respectively. Miners are to receive 10s. a day. This award will remain in force until the end of 1910. The hours of labor are fixed at 48 a week. The arbitrator declined to interfere with the contract system or to compel the Proprietary Company to continue work. Justice Higgins' award provides for wages on the same scale as heretofore. The Proprietary Company has appealed from this decision.

According to the *Queensland Government Mining Journal*, Dec. 15, 1908, the highest mine in the world is the Santa Bolivia, South America, which is at an altitude of 18,000 ft. above sea level.

The National Lead Company

The report of this company, which is the largest consumer of lead, for the year ended Dec. 31, gives the following comparative statement of conditions at the close of 1907 and 1908:

	1907.	1908.
Common stock.....	\$20,855,400	\$20,855,400
Preferred stock.....	24,367,600	24,367,600
Surplus.....	4,294,204	4,458,455
Accounts payable.....	176,470	222,797
Total liabilities.....	\$49,493,674	\$49,704,252
Investments.....	\$38,062,111	\$38,269,377
Stocks on hand.....	5,700,865	7,262,231
Accounts receivable.....	3,506,334	3,258,368
Cash.....	1,224,364	933,676
Total assets.....	\$49,493,674	\$49,704,252

The company holds unissued \$4,334,600 of its common and \$632,400 preferred stock. The net earnings and payments for 1908 were:

Net earnings.....	\$2,902,753
Dividends, 7 per cent. on preferred stock.....	\$1,705,732
Dividends, 6 per cent. on common stock.....	1,032,770
Total.....	\$2,738,502
Surplus for 1908.....	\$ 164,251
Previous surplus.....	4,294,205
Total, Dec. 31, 1908.....	\$4,458,455

As compared with 1907 the net earnings showed a decrease of \$39,493. Expenditures for maintenance and repairs were \$239,193, which was charged to current expenses.

The report says: "The volume of business done suffered a shrinkage in the aggregate of but 2 per cent. in comparison with the year 1907, which was the largest in your history. The protection afforded by the varied character of your output was demonstrated most forcibly in a year of general depression and the early expectations of the management were more than realized in both tonnage and profit. The properties which you have from time to time acquired have also generally contributed to your prosperous condition and in no instance failed to pay, not only fixed charges, but some additional measure of profit. Inventories at all points and of every character have been as usual taken at protective values and lower than any raw material prices yet quoted.

"Business for the current year exceeds that of last but this was to be expected. It halts in some features and we do not look for confident trade until all doubt as to the future tariff is dispelled. Competition is increasing but your position will be maintained by such conservative activity as may be necessary to protect trade. New articles are added to the list of your manufactures of lead in its various forms as its uses are extended or when it is found useful and profitable to conserve existing tonnage. One of the companies in which you are interested, and which makes shot on a large scale, has prepared plans for the manufacture of metallic and shot gun ammunition, but these are held in abeyance for the time being. Your mining and smelting interests have a

plant in process of erection for the manufacture of sublimed lead, a product which now enters into a variety of uses, including ready mixed paints."

High Stamp Duty on the Rand

In the light of American practice the statements published in the *South African Min. Journ.* of Feb. 6, 1909, regarding milling methods on the Rand are of interest. According to that publication there are now on the Rand 120 tube mills in operation, hundreds of stamps dropping which weigh between 1250 and 1800 lb., the average stamp duty for the whole Rand during December, 1908, having been 6.64 ton per stamp per 24 hours. Three mills are engaged in construction work which will result in duties of 10 tons per day or week. At the West Rand Consolidated 1800-lb. stamps to deal with 12 tons of ore each per day are being installed.

That the economic value of stamp duties is generally appreciated in South Africa is, shown by the fact that over 28 com-

deep. The principal development work during the year has been confined to the 1300- and 1400-ft. levels, where large bodies of high-grade sulphide ore have been opened. This ore occurs in lenses up to 30 ft. in thickness and 180 ft. in length. The Hoatson shaft was sunk 252 ft. during the year, and is now 1680 ft. deep. Most of the development work at this shaft was on the 1300-ft. level, and ore has been opened up that meets with the management's highest expectations.

The production of refined copper for the year 1908 was 21,924,359 lb., as compared with 9,602,553 lb. for the year 1907. The increase in production during 1908 was due to both an increase in amount of ore treated and through a better grade of ore.

Sectional Gin Poles

At mines, mills and smelters it is often necessary in construction work to have a long gin pole. Usually these gin poles are in one piece, even if very long, because there is a prejudice against spliced

SPlice FOR 12x12-IN. SECTIONAL GIN POLE

panies use stamps giving duties of over 7 tons, and during 1908 the average duty for the whole region was increased in each month. At the opening of 1908 there were 72 tube mills in operation and the average stamp duty was 5.8 tons per day. By January, 1909, the average duty had been increased to 6.56 tons per 24 hours, and 118 tube mills were in operation.

Superior & Pittsburg Copper Company

The report of the Superior & Pittsburg Copper Company, March 20, 1909, shows that for the year ending Dec. 31, 1908, the operating expenses at the mine and smelter were \$2,490,858; construction, \$30,939; salaries and general expenses, \$36,049; freights, refining and marketing, \$264,868; total assets, \$1,216,193; liabilities, \$1,695,775. Balance, assets, \$459,581. The development work during the year at the Cole, Junction and Hoatson shafts consisted of drifting, 24,666 ft.; raises, 3388 ft.; winzes, 42 ft.; stations, 1016 ft.; or a total of 29,572 ft. The Junction shaft was sunk 206 ft. during the year, and is now 1555 ft.

or sectional rigs. Sometimes it is difficult to obtain the long timbers necessary and then a spliced pole similar to the one described in *Eng. News*, Jan. 28, 1909, by W. E. Boldsworth can be used. These sectional gin poles, which the Dover Boiler Works, Dover, N. J., uses in raising heavy iron chimneys, have a total length of 92 ft. and a lifting capacity of 10 tons. They are so made that if they should fail rupture will take place outside the splices. The poles are made of 12x12-in. long-leaf yellow pine and each pole consists of two 36-ft. lengths and one 20-ft. length. The splices are made with angles arranged as shown in the accompanying illustration; each splice is in four duplicate parts joined by 3/4-in. bolts spaced at 6-in. centers along the splice plates. This manner of splicing is especially applicable for timbers of smaller size.

The features which commend this form of splices are that no holes are bored in the timbers, the ends of the timbers need not butt, any splice plate is interchangeable with any other, and, if any loads beyond the normal capacity of the poles are to be raised, truss bars can easily be attached to the splices.

Personals

Mining and metallurgical engineers are invited to keep THE ENGINEERING AND MINING JOURNAL informed of their movements and appointments.

C. Colcock Jones is in the Tintic district in Utah, on professional business.

W. M. Brewer was in Victoria, B. C., recently, after having spent some time in southeast Alaska.

W. S. Keith, of Seattle, Wash., is making an examination of copper properties in Douglas county, Oregon.

C. Willard Hayes and David T. Day, of the United States Geological Survey are investigating the oilfields of Mexico.

J. W. Bryant, one of the Tyee Copper Company's engineers, has returned to Victoria, B. C., from a trip to Mexico.

R. B. Brinsmade expects to reach New York about April 27 from San Domingo, where he has been exploring a mining concession.

George H. Garrey, Mexican representative of Spurr & Cox, has recently been engaged in geological work in the vicinity of Mapimi, Durango.

J. D. Hurd, of Fernie, B. C., general manager of the Crow's Nest Pass Coal Company is on a business visit to Chicago, St. Paul and other cities.

Charles Emmerson, manager of the mines of the West Canadian Collieries, Ltd., recently left Bellevue, Alberta, on a three months' trip to England.

William M. Gibson, assistant superintendent of the Calumet & Hecla mines, has returned to Calumet, Mich., after spending three months in Europe.

John C. Brydon has been elected president of the Isabella-Connellsville Coke Company. He is now general manager of the Western Kentucky Coal Company.

John Hampson, formerly superintendent of the Brown-Alaska company's Mamie mine, on Prince of Wales island, Alaska, recently left British Columbia for Arizona.

Juan Felix Brandes has been examining mines in the Harz Mountain district in Germany. He will shortly return to Colorado and Mexico, after an absence of six months.

Bradley Stoughton has opened offices as consulting metallurgical engineer in the City Investing building, 105 Broadway, New York, and in the Betz building, Philadelphia.

J. E. Johnson, Jr., has resigned his position as superintendent of Princess Furnace at Glen Wilton, Virginia. He will be for some months at Wilmington, Del., engaged on special work.

H. F. West, having spent the winter inspecting the Cobalt district in Ontario, is proceeding to El Oro, Mexico, to join the staff of R. M. Raymond, general manager of El Oro Company.

J. M. Ruffner, manager of the North Columbia Gold Mining Company, of Cincinnati, O., has gone north to operate the company's hydraulic gold mines in Atlin, B. C., for the ensuing season.

Superintendent Lawton, of the Quincy mine at Houghton, Mich., is visiting various mining and milling plants in Utah. He is accompanied by James Shield, superintendent of the Quincy stamp mill.

J. E. Spurr, who for the last three months has been engaged in geological examination work in various mining camps in Mexico and also in Arizona, has returned to his headquarters in New York.

J. Morgan Clements, mining geologist, and Frank Klepetko, metallurgist, have taken offices together at No. 42 Broadway, New York City. Mr. Clements has gone to Cananea, Mexico, on professional business.

James W. Paul, now connected with the Government testing station in Pittsburgh, sailed for England April 10. He will spend some time studying mining methods and safety appliances in England, France, Belgium and Germany.

Godfrey D. Doveton, metallurgical engineer for Spurr & Cox, Inc., has returned to Mexico City from Guanajuato, where he has been, for the last three months, in charge of extensive cyanide and other milling tests for the Guanajuato Development Company.

Obituary

William H. Sayre died in Bethlehem, Penn., April 7, aged 78 years. He had lived in Bethlehem practically all his life and had been for 57 years connected with the Lehigh Valley interests. He was an officer of the Lehigh Valley Coal Company from its organization, and for a number of years had been second vice-president and in charge of the sale and distribution of coal. He was a brother of the late Robert H. Sayre, who was chief engineer and afterward president of the Lehigh Valley Railroad Company.

Dr. Persifor Fraser died at his residence, Philadelphia, April 7, aged 64 years. He was born in Philadelphia and graduated from the University of Pennsylvania in 1802. After serving two years in the army, he went abroad and studied three years at Freiberg in Saxony. Doctor Fraser held many important positions in geological and chemical research work. At different times he was lecturer in chemistry, assistant professor of natural philosophy and chemistry and professor of chemistry at the University of Pennsylvania. In 1874 he was appointed assistant geologist of the second Geological Survey of Pennsylvania, in charge of the southeastern section of the State. He was an editor of the *Franklin Institute Journal*

from 1882 to 1894, and in 1889 was made professor of horticultural chemistry by the Horticultural Society of Pennsylvania. He was the author of several books and of many technical papers. In recent years he had devoted much time to the study of handwriting, and published a book on that subject.

Societies and Technical Schools

American Institute of Chemical Engineers—The semi-annual meeting will be held in Brooklyn, N. Y., at the Polytechnic Institute, June 24 and 25. The program will consist of papers, excursions and an exhibit of chemical engineering apparatus.

Institution of Mining and Metallurgy—The annual dinner will be held at the Hotel Cecil, London, April 30, 1909. The secretary of the Institution has prepared an exhaustive index to the first 15 volumes of the *Transactions*, comprising about 250 pages (in double columns) of references and cross-references. The cost is 7s. 6d. per copy.

Utah State School of Mines—The Senior class of mining engineers will take an extended trip this spring through the mining districts of Colorado, Nevada, Arizona, New Mexico, Mexico, California, Idaho and Utah. This is the most extensive trip ever undertaken by any technical-school graduates. Arrangements have been made for the inspection of the most important mines, mills and smelters.

The John Fritz Medal—The John Fritz medal for 1900 has been awarded by the board of award specially selected for the purpose and consisting of four members of each of the national engineering societies, to Charles T. Porter, for his work in advancing the knowledge of steam engineering, and in improvements in engine construction. The public ceremony of the presentation of the medal to Mr. Porter took place in the large auditorium of the Engineering Societies building, No. 29 West Thirty-ninth street, New York, at 8:30 p.m., on Tuesday, April 13, 1909. Besides the simple ritual of the presentation of the medal, in the presence of invited guests and distinguished representatives of engineering, there were addresses by representatives of the four groups of the profession most concerned, as follows: "The Debt of Modern Industrial Civilization to the Steam Engine as a Source of Power," Dean W. F. M. Goss, University of Illinois; "The Debt of the Modern Steam Engine to Charles T. Porter," Prof. F. R. Hutton, Columbia University; "The Debt of the Era of Steel to the High-speed Steam Engine," Robert W. Hunt, Chicago; "The Debt of the Era of Electricity to the High-speed Steam Engine," Frank J. Sprague, New York. Henry R. Towne was chairman of the committee of arrangements.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at San Francisco, Butte, Denver, Goldfield, Indianapolis, Toronto, Berlin, Mexico

REVIEWS OF IMPORTANT EVENTS

San Francisco

April 7—Arrangements have been made by a firm of local shipping men to place a fleet of seven vessels on the service between this city and New York. Three vessels are already at sea, and now four new four-masted steel sailing vessels are to be added, the largest sailing ships afloat, each with a cargo capacity of 5500 tons. About 120 days will be allowed for the trip, which will make about six round trips a year. The minimum freight rate is to be 30c. and the maximum 35c. Two steamships are in the line, each of 6000 tons. Not only is this an important matter for shippers of many kinds of California products, but for certain mining interests as well. The freight rates by rail from this city to New York have been for years virtually prohibitive for certain mineral products, notably asphalt, chrome, magnesite and manganese. When there was a fleet of sailing vessels carrying freight to New York years ago, chrome and manganese ore were mined here and shipped, but of late years most of the mines have been closed for want of a market. Magnesite cannot profitably be shipped under present railroad rates, nor can the other substances named. Only one or two chrome mines are being worked in California, and scarcely any manganese mines. The greatest benefit to be derived from these new lines of vessels will be for the California asphalt industry.

Large quantities of asphalt are made at the oil refineries not only in Los Angeles, but around San Francisco bay. Some of the California oil carries as high as 20 per cent. asphalt, and so much is made that there is not enough local demand to consume it. For this reason thousands of tons are made into coke. If there is an outlet by sea at reasonable rates, such as is now to be established, this asphalt can be shipped to New York and other cities.

The Camminetti bill to create a consulting board looking to a more general resumption of hydraulic mining in the central part of the State failed to become a law. It passed the Senate, but was defeated in the Assembly. The valley people looked with suspicion upon the proposed measure, fearing that too many hydraulic mines might be permitted to start up. This is another evidence of the fact that hydraulic mining will never again become an industry of great prominence in this State.

The Mercantile Trust Company, of San Francisco, has commenced suit to foreclose on the property of the San Francisco

& San Joaquin Coal Company under a deed of trust for \$500,000. The coal company gave the deed of trust to secure the payment of a bond issue of that amount. The agreement also provided that the coal company was to pay the bank 5c. for every ton of merchantable coal mined and to put in escrow 4975 shares of the capital stock of the Alameda & San Joaquin Railway Company. Neither of these provisos was carried out. The coal mines are those sometimes known as the Treadwell mines, in Alameda county. The Treadwells—of Alaska fame—put a fortune into these properties, but the coal was of poor quality and there was not so much as supposed. They tried briquetting the product but that failed. There was several subsidiary companies, one for the manufacturing of window glass from the glass sand, brick and pottery from the clay, etc. A manganese property was also included. The brick and pottery works are still active.

The Keane Wonder mine, in Inyo county, one of the large producers of the State, has put into commission a new 100-ton cyanide plant, which begins work on an accumulation of about 20,000 tons of tailings. There is a 20-stamp mill on the property, which is kept in constant operation on high-grade ore. The capacity of this mill is to be doubled, to keep up with the cyanide tonnage.

The United States grand jury at Carson, Nev., has returned indictments against L. L. Partick and M. B. O'Farrell, two Goldfield "brokers," charging them with using the mails fraudulently in connection with the promotion of mining stock. It is understood that this is the first of a series of indictments to be considered by the grand jury, and a general hunt for fraudulent stock transactions is expected in Nevada.

Tonkins, Sanford and others have sued W. H. Remington and J. D. Barber for possession of the Patricia, Marie and Sanford mines near Columbia, Tuolumne county. The defendants made an agreement to do certain work under an option and to put in certain machinery to unwater the mines, to make certain payments, and to pay 50 per cent. of the net proceeds of operation. The plaintiffs say these things were not done as agreed and ask that the mines be returned to them.

At Salome, in Ellsworth district, Inyo county, on the Arizona-California branch of the Santa Fé railway, where discoveries of high-grade ore were recently made, things are quite lively just now. Eastern people have purchased a half in-

terest in the Bonanza mine and made a substantial payment, thus giving the new camp a good start-off.

Butte

April 8—Judge Hunt, of the Federal district court handed down his decision last week in the case of the United States against the Northern Pacific Railway and its subsidiary companies. The suit was brought for the Government by Special Attorney T. J. Walsh for the purpose of securing to the Government certain coal lands in the Red Lodge district, Carbon county, of the value of \$2,012,000 now held by the railroad. Years ago the railway took this land from the Government in exchange for land along its right of way. At the time it was supposed that the land was non-mineral in character but it was later found to contain coal deposits of great value. By the decision the Government is given the lands in question and the court holds that, even though the Government engineers had previously classified the land as non-mineral in character, yet this classification was not conclusive, and when proof was made that the lands were in truth valuable for their mineral deposits the title of the railway to the lands must of necessity fail. In view of the amount involved the case will in all probability be appealed to the United States circuit court of appeals.

The monthly report of the United States assay office at Helena states that there has been a gain of \$108,378 in the amount of gold received during the first quarter of 1909 over that received during the first quarter of 1908. The total amount of precious metals received at the office for the first quarter of the current year is \$458,574. For the month of March, Madison county leads with a production of \$42,081.

E. W. Beattie, of Boston, has instituted action in the Federal district court for the purpose of securing a receiver and winding up the affairs of the Bald Butte Mining Company. In his petition he states that the company is indebted to him in the sum of \$20,145 and that its other debts are of such amount that a sale of the entire property will be necessary before payment can be made.

J. A. Murray has begun an action in the local district court against the Monitor-Tunnel Mining Company, W. S. Switzer and James H. Maloney, for the purpose of compelling the transfer on the company's books of 2,146,650 shares of stock

which plaintiff alleges he is the owner of. In his complaint Murray states that he advanced money to Switzer and received the stock as collateral and that the latter has never paid the money borrowed and that therefore the plaintiff is entitled to the transfer.

Work on the new Gilmore & Pittsburg Railroad between Armstead, Montana and Salmon City, Idaho, is being pushed with all possible speed. Attorney Wheeler, of Pittsburg, who has been securing the right of way for the company, states that between 3000 and 4000 men will be put to work on the road within two weeks' time.

The Monida Trust Company has recently brought suit against the Red Metal Company for the purpose of securing the partition of the Mountain Chief lode claim, situated in the Butte district. The complaint states that the trust company is the owner of an undivided one-third and the mining company of the remainder.

The Davis-Daly has been the topic of much speculation during the last several weeks. At the Colorado shaft a crosscut on the 1400 level, which recently intersected a large vein of low-grade ore, is being pushed ahead, and it is expected that another vein will be cut in a short time. A new 22-drill Nordberg compound compressor, electrically driven, and ore bins of 500 tons capacity are being set in place.

Oscar Rohm, of the Pittsmtont company, has left for the East, and an official announcement is expected in the near future concerning the reported consolidation of the Pittsmtont and East Butte.

Denver

April 9—It is stated in the daily press here that the president of the International Smelting and Refining Company, John D. Ryan, is coming here soon in the interests of his company for the purpose of determining if it shall enter Colorado, and if so, where its plants shall be built. He is to be met here by Dennis Sheedy of this city, the vice-president of the company, and they will make a tour of inspection together.

The Portland Gold Mining Company now proposes to build a mill at the mine on Battle mountain to treat its enormous dump and its low-grade ores, and in view of this expenditure the directors have decided to reduce the quarterly dividend from 4 to 3c. per share. The March production of the Vindicator mine is given at 2000 tons of ore, averaging two ounces of gold per ton. The Elktion Consolidated Mining and Milling Company has declared a dividend of 1½c. per share, payable April 24. The Union Leasing Company is credited with a production in March of nearly 3000 tons of gold ore, of a gross value of about \$75,000. This product came from the Gold Dollar, El Paso, Pinto and Deadwood mines.

After a year's idleness the mill of Strat-

ton's Independence, Ltd., is now running on the low-grade ore of the dumps, this enforced shut down being due to financial reasons; the company was, however, re-organized last fall and ample capital provided to pay off all indebtedness and provide for future needs; in fact the published report of the company shows that \$250,000 of new capital was put into its coffers, and it is well known that the debts were about \$100,000. The dump mill was so far completed last spring that it could be operated in ordinary weather, but the winter has been so severe that no attempt was made at operation until March, and even then they had to shut down a few days on account of freezing in the concentrating department. It is hoped that the mill will soon be in continuous and successful operation as it is a bold attempt to treat the low-grade ore by fine grinding, concentrating the sulphotelluride ores, and cyaniding the tailings. The dump is said to average \$3.70 per ton, and at best the profits cannot be large in a 100-ton mill. However, the company has the funds to treble the plant whenever success is demonstrated, and should it be shown that ores of \$3.50 gross value can be treated at a profit, it will add greatly to the value of the Cripple Creek district, and the operation of this mill is consequently followed with much interest.

In the San Juan region, Silverton has been relieved from the snow blockade and over 7000 tons of concentrates have been sent from the neighboring mines to the Durango smelter during the month ending April 8.

The Sigafos, one of the many boring machines used for rock tunneling without the use of explosives, has been installed on Columbia mountain, near Georgetown, and is scheduled for a practical test as soon as ample water is available to insure a steady run. The demonstration will be watched with interest by mining engineers of this State.

The Mohican, supposed to be an extension of the Gold Coin vein, just above the town of Victor, also reports a strike of five feet of \$20 ore at the 700 level. The leasing company operating the mine is now prospecting for the same shoot on the 1000 level. The Friday, an adjoining parallel vein to the Hoosier, one of the early big producers of Tenderfoot hill, reports a new ore shoot discovered at the 200 level. The values are said to run from one to four ounces per ton. A 5-ft. vein of shipping ore is also said to have been discovered on the Ocean Wave, on Battle mountain. An aerial tram three miles in length will be built from the Midget mine, owned by the Gold Issue Company, on Gold hill, to the mill of this company between Mineral and Carbonate hills. The mill has been remodeled, and will treat 100 tons per diem.

A report has just come to hand of the discovery of a shoot of that phenomenally

rich telluride of gold product in the W. P. H. on Ironclad hill, Cripple Creek district, and which in 1904 was a spectacular producer, ore worth as high as \$6000 per ton in gold being then produced from the 245-ft. level, and \$315,000 was taken out. The new vein is said to be four feet wide. The ore is being sacked for an initial shipment and the orehouse and workings meantime are patrolled by watchman day and night. The ore is mainly silicified breccia and occurs near the contact with the outlying schist.

In Leadville, the Garbutt mine, which adjoins the Ibox group (locally known as the Little Johnny), on the south, has made a strike of rich gold ore. It is worked by lessees, and owned by the Cheesman estate. There are upward of 150 leasers working on the Little Johnny, and all of them are doing well.

In closing out a loan in New York, a sale of securities at auction recently resulted in the transfer of nearly 10 per cent of the stock of the United Rico Mines Company, 276,832 shares being sold, together with 1000 shares of King Edward Silver Mines Company, of Cobalt, and \$55,000 in 6-per cent. bonds of the United Rico company.

Goldfield, Nevada

April 6—The estimated value of the output of the Goldfield mines for March is: Consolidated Mines, \$1,074,000; Goldfield Florence, \$95,000; Combination Fraction, \$88,000; Daisy, \$17,500; other mines and leases, \$20,000; aggregating \$1,294,500.

Tonopah ore shipments for the week ending March 27 were: Tonopah Mining, 3250 tons; Montana Tonopah, 775; Belmont, 300; MacNamara, 270; Jim Butler, 200; West End, 130, and Midway, 100 tons; total estimated value, \$125,000.

As a result of the visit to Goldfield of James F. Calbreath, Jr., secretary of the American Mining Congress, Oct. 11 has been chosen for the date of the Goldfield meeting. Various committees were appointed and a strong effort will be made to secure low railroad rates. The mint at Carson was unable to treat a \$300,000 bullion shipment from Goldfield last week, owing to insufficient facilities. The shipment in question was forwarded to San Francisco. The superintendent of the mint has appealed to Washington for additional help, but thus far has been unsuccessful.

The Nevada-California Power Company has let contracts for extending its lines from Millers to Manhattan and Round Mountain; the material is now arriving at Millers and construction will start at once. The introduction of electric power in these camps will do away with a great handicap that has faced operators heretofore and will serve to make possible the operation of many properties now lying idle. The output of the Goldfield mines for the week

ending March 27 was 6400 tons, estimated value, \$330,000.

Grading has begun for the car shops to be erected at Las Vegas, Nev. This is to be a division point on the Clark road. It is claimed that the shops when completed will furnish employment for about 400 men.

In a decision for the defendant, Judge Peter J. Somers, of the District Court, holds that the good faith of the owner of mining claims in expending money for the annual assessment work, is all that is necessary if he, the owner, can prove that the money actually went into the ground. The action was based upon the question of sufficiency of labor performed on a group of four claims east of Goldfield, on three of which shafts 4x6x10 ft. deep were sunk, and on the fourth a shaft of similar dimensions already existing was deepened 8 ft. The owner, a nonresident of Goldfield, arranged by letter to have the work done, a contractor agreeing to do the annual assessment work for the sum of \$400. The work was performed and the money paid. Later the claims were jumped by men who claimed that shaft of the above dimensions was not worth \$100, and was an evasion of the United States statutes, the court holding the contrary.

Governor Dickerson has appointed Edward Stewart, of Manhattan, as State mine inspector at a salary of \$3000 per year. Mr. Stewart will assume his duties at once and will name his assistant who will receive \$2400 per year.

The executive board of the American Mining Congress in accordance with the plans of that organization to appoint a vice-president in each of the Western mining States, recently appointed George Wingfield to that office for Nevada.

Indianapolis

April 12—That the big steel mills at Gary, Ind., are preparing to get a large part of their soft coal from southern Indiana is shown by contracts now being written—and there is every reason to believe that they will be signed—for the delivery, beginning not later than May 1, of 3000 tons of coal daily to that point. Most of the coal, according to advices, will be produced by the mines in Sullivan, Clay, Green and Vermillion counties, but there are indications that a part of it will come from the Gibson and Warrick county fields.

The supply of Indiana coal which the Steel Corporation will take will mean at least 50 carloads a day. The Corporation is interested in some mines and coal lands near Terre Haute, and may also secure some fuel from that field. The news is welcomed by operators and miners alike, since it assures steady and increased work for miners.

Toronto

J. M. Laing, president of the Gowganda Board of Trade, publishes a statement to the effect that there is now no danger of a shortage of food supplies in the camp on the break-up of winter communications, as was at one time feared. There are, he states, 1050 tons of supplies in the hands of merchants, while 600 teams on the road from Charlton and 200 teams on the road from Sellwood to Gowganda are busy hauling in additional supplies, mostly provisions.

Mexico City

April 4—There is much interest in Mexico in special and improved ore-treatment processes to meet the conditions of the metal market, and to utilize the large deposits of complex low-grade ores. The most extensive dry-concentration experiments have been carried on at the Tiro General mine, at Charcas, S. L. P., using the Sutton-Steele method, and the result has been a commercial success. The ore here is mixed sulphides of copper, iron, lead and zinc, finely crystallized, and with the individual crystals interwoven in the mineral so as to make the application of the ordinary gravity concentration methods of no avail. The di-electric process was also applied at this mine as an adjunct to the pneumatic concentration method. The San Francisco del Oro mine, near Parral, has also been working on the application of the pneumatic concentration method. A modification of the dry-concentration tables was developed at the mine and it is reported that the ore could be successfully treated by this method. However, there has been a change of management and a new manager is now on the ground to try some of the Australian methods for the treatment of the ores.

The Avino mines in Durango have tried oil concentration unsuccessfully, and now the London board is talking of smelting the ore. At the Calera mine in Chihuahua the Sutton-Steele pneumatic tables are being used in separating zinc-lead ore. A testing plant, to demonstrate the Potter flotation method, is being erected in Mexico City by an English and Australian company that has been instrumental in developing these processes at Broken Hill and at other Australian camps. The company will also introduce a new electro-magnetic process from Germany. In the Parral camp the treatment of the zinciferous ores by magnetic methods is in use successfully and extensively.

The beneficiating of the complex ores is a new feature in the development of Mexican mining and it is likely to be far-reaching for there are many localities containing important ore deposits that cannot be marketed or treated by any of the ordinary methods. The problem is

being taken up in the same spirit as was the cyanidation of the silver ores a few years ago, and it is expected that with the experience gained in the United States and in Australia that the men at work on the complex ore problems of Mexico, will meet with a measure of success that will materially benefit the industry.

The Mexican congress will take up the consideration of the new mining law at the session which is now convened. The law as submitted by the government and indorsed by the executive department, eliminates the objectionable clause 144, and the other clauses which were considered unfavorable. The law is mainly a codification of the existing statutes, decrees and rulings of the departments, and is very much needed, as there has been no general mining legislation enacted since 1892. Some of the points in it are considered favorable to the industry and in the main the enactment of the law, with the objectionable clauses removed, will be advantageous to the interests of foreign investors.

During the first half of the fiscal year, 2150 title deeds to mining lands were issued covering 39,987 hectares, a decrease from the corresponding period of last year of 28 per cent.

The Institute of Geology of Mexico has just published a complete bibliography of Mexican mining and geology to 1904, prepared by Sr. José G. Aguilera, director. The Geographical Exploration Commission has completed a large map of the state of Tamaulipas and will shortly issue some sheets of the Puebla and Tlaxcala map. Field work is being carried on in Sonora, Chihuahua, Morelos, Oaxaca and Yucatan.

The International Smelting & Refining Company, according to reports, has dropped negotiations for the Torreon smelter owing to a disagreement as to price, and so far the new company has not made any direct move in the Mexican field, although it is known to have made some general investigations here recently.

Berlin

April 2—It is reported that Prussian government has introduced a bill in the Diet forbidding foreigners from acquiring mineral properties and operating mines within Prussia without the especial permission of the King or the authorities representing him.

It is assumed that this bill is largely due to the discussion which has been going on for some weeks among those interested in the potash industry, regarding the probable purchase of potash mines in Prussia by American fertilizer combinations, so as to render themselves independent of the German potash syndicate.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Alaska

The latest news from the old Koyukuk diggings on Nolan creek are encouraging. A big clean-up for the season is anticipated. Mining activity at Circle City has again revived and some pay streaks have been encountered. It is reported that wages are \$10 per day and men from the neighboring towns are being urged to accept employment.

KLONDIKE

There is renewed activity here and a good output of gold from lode and placer claims is anticipated. On the Dome last year a large amount of prospecting was done and an air compressor and drills have been installed. Lode mining from now on will go hand-in-hand with placer mining in the Klondike country.

TANANA

Brumbaugh, Hamilton & Kellogg have just completed the installation of the first stamp mill in this district. A second stamp mill will be installed very soon and is now being hauled in by sleds over the trail from Valdez. The installation of these two mills has given quite an impetus to lode mining.

Empire—A tunnel is being driven on this property and a number of good quartz lodes are reported in the immediate vicinity.

VALDEZ

Tacoma Copper Company—The property is at the head of Cordova bay. A plant for the treatment of ore, a large dock, and buildings for the accommodation of employees will be erected at once. The company proposes to spend \$150,000 in development work.

Galena Bay—With the tunnel in 1500 ft. a diamond drill, at a depth of 300 ft. farther, struck an orebody 40 ft. in thickness. The ore contains a fair percentage of copper.

Arizona

COCHISE COUNTY

Phelps, Dodge & Co.—At the annual meeting held in New York, James Douglas, Cleveland H. Dodge, Arthur C. James, James McLean, George B. Agnew, E. Haywood Ferry, Francis L. Hines, George Notman and William Church Osborne, all of New York, were elected directors.

Swisshelm Development Company—The property is about 16 miles southeast of Courtland. The shaft is now 80 ft. deep and is in rock that carries both gold and silver.

Heffern Mining—The company has fifty claims in the Swisshelm district, thirty miles northeast of Bisbee. Thirty-two men are employed. The two-compartment shaft is now 320 ft. deep. Native gold, silver and copper can be panned from the lead ore in the bottom of the shaft.

Copper Queen—A power house, 45x70 ft., is being built at the company's workings, in Courtland. The building will contain an air compressor, which will furnish air for the several working shafts. All the power used will be on an electric basis.

Courtland—A post office was established recently and the town is growing rapidly. The Southern Pacific and El Paso & Southwestern railroads will both be in the camp within a few weeks and ready to haul ore to the smelters at Douglas.

GILA COUNTY

Old Dominion—Drifts on the 1000, 1200 and 1400 levels in the United Globe ground are being driven to strike below the workings of the old Hoozier mine. Another furnace was blown in at the smelter recently, and in the future four furnaces will be kept in operation.

Gibson—A winze from the 400-ft. level has encountered a rich body of chalcopryrite. The property was sold recently to a Boston syndicate.

Inspiration—Two crosscut adits, and one drift are in low-grade sulphide ore. Two shafts are being sunk. Gasoline hoists are being installed. Churn drills will be used to prospect portions of the ground.

Superior & Boston—Shipments are being made to El Paso at the rate of 50 tons per day. February shipments averaged 0 per cent. copper, with some silver.

National—A 3-compartment shaft has been started. The new shaft is for the development of the Black Hawk vein.

GRAHAM COUNTY

Arizona Copper—March production was 297,000 lb. as compared with 2,546,000 lb. for February.

California

ALPINE COUNTY

Nevada-Hercules—The Loope prop-

erties at Loope have been started and the company will begin operations in both mine and mill.

AMADOR COUNTY

Garibaldi—After extensive surface stripping by hydraulic process, the gravel channel has been opened and is proving rich in both coarse and fine gold.

BUTTE COUNTY

E. Gunn has sold the old Gunn or Blue Hog mine at Magalia to D. Casterline for \$20,000. A company will be formed in Los Angeles to work it.

Magalia Consolidated—This company was organized by S. P. Moody and Mc Cubbin Brothers, of Oroville, to work the old Mineral Slide mine south of the Mammoth Channel Company's mine.

CALAVERAS COUNTY

Mike Tisher—Porteous & Oliver have sunk a shaft on this mine and have bottomed the old workings. The ore is heavily sulphureted, but is of high grade.

EL DORADO COUNTY

Alpine—Since George Wingfield and associates gave up the bond, Mr. Lane and his associates have kept at work on a wide vein of \$8 rock. Twenty men are employed.

Manhattan - California—Development work has been renewed. A heavier surface plant is to be put in. W. P. Hyatt is superintendent.

INYO COUNTY

Casa Diablo—The mill has been started with ore enough for a 40-day run.

Skidoo Mines Company—The 15-stamp mill is turning out bullion.

MONOC COUNTY

Hess—A good grade of ore from the 3-ft. vein in this mine is being milled.

NEVADA COUNTY

Giant King—The machinery for the new 20 stamp mill is on the ground and will be set up as soon as possible. The lower tunnel is expected to cut the vein in a few days.

Peck-a-Boo—In this mine, Grass Valley district, a small ledge of high-grade ore has been struck.

PLACER COUNTY

Begole Mines Syndicate—This Gold-field company, holding a bond on the

Annie Laurie and Alameda group of claims, six miles from Colfax, is about to install a 150-h.p. electric plant. An air compressor has been installed.

Cash Rock Dredge—The Long Beach-Los Angeles company, owning the dredge which was at work in the north fork of the American river near Forest Hill is being reorganized with a view to building a new dredge. The old one was damaged in the winter floods. So far the dredging work in that section has not been profitable.

Colorado

LAKE COUNTY—LEADVILLE

Penn—Two hundred tons of ore are being shipped daily from this Breece hill property and development work is being pushed in new territory. The ore is obtained mainly from the lower levels.

Grabutt—In recent development work near the Little Johnny, a body of high-grade gold-bearing quartz was encountered. About 20 tons per day are now being shipped. Several years ago this property shipped mainly copper ore.

Iron Silver—It is announced that Mark Woodruff, of Detroit, Mich., one of the officers of this company, is to take charge of the property until the successor to Waldemar Arens is appointed. Only a limited force of men are to be employed on the company account until Mr. Woodruff's arrival. Lessees, however, are working to full capacity.

Butte—Lessees on this claim in the south Mosquito district recently opened a 2-ft. vein of gold ore.

Houston—The tunnel is now in 93 ft. Several promising streaks have been encountered.

Dinero Tunnel—Regular shipments are being made from the orebody recently opened in this tunnel and the bore is being driven ahead to develop claims farther north under control of the same interests.

Fanny Rawlings—In the lower workings on Breece hill a good body of ore has been opened and the mine is shipping 20 tons daily.

GILPIN COUNTY

Ann Rutledge—The Mann lode in the Vermilion district has been sold to the Ann Rutledge Gold Mining Company, of Youngstown, O. This property produced high-grade ore in the early days and is now to be unwatered and the shaft sunk deeper. The upper workings will also be prospected.

East Pewabic—A lease for two years on this mine in the Russell district has been granted to M. Edwards and associates. It is announced that the shaft will be sunk 200 ft.

TELLER COUNTY

Ophir—The new oreshoot opened on the 1000 level has been exposed for a distance of 65 ft. and stoping will be commenced at once. Two cars of ore have already been shipped.

Doctor-Jackpot—A suit for \$2,245,000 for ore alleged to have been unlawfully taken from the Doctor-Jackpot properties has been filed against the Work Mining and Milling Company. This ore is alleged to have been taken from veins Nos. 1 and 2 and the Timber Drift vein.

Iron Clad Hill—The recent rich discovery on the W. H. P. has resulted in considerable activity on Ironclad hill. Lessees are sinking on the Teutonic, Seven Thirty and other properties in that section.

Prince Albert—The Union Leasing Company has begun shipping ore from this Beacon hill property. The tunnel is now in 1150 ft. and is to be driven an additional 400 ft. to the north end line.

Idaho

IDAHO COUNTY

Reports from Elk City are discouraging. The camp is 70 miles from the railroad and supplies are high in price. Only one mine is at work, employing 10 men. There are a number of idle 10-stamp mills. All of the work is in the prospecting stage.

Indiana

GREENE COUNTY

Vandalia mine No. 3 has been closed. This is the oldest mine in the district, and employed nearly 100 men. The mine is not all worked out, but the remaining coal will be taken by the men of mines Nos. 2, 4 and 6, which are connected with No. 5.

A company has been formed at Linton to take over the city electric light plant. The company proposes to open a new mine and erect a plant at the mouth of the mine and furnish electricity to a number of cities in the territory.

VIGO COUNTY

Plans and arrangements are being made as rapidly as possible, to erect a safety device station near Terre Haute. A number of coal operators, mine superintendents, officials of the United Mine Workers and Terre Haute city officials will go to the Illinois State University at Urbana, April 12, to witness a demonstration of the safety device for which it is intended to establish a station in Terre Haute.

Louisiana

The production of petroleum in March was 273,500 bbl., being 24,800 bbl. less than in February. Shipments were 91,542 bbl. by rail and 18,829 by pipe-line; a total of 110,362 bbl. In March 19 new

wells were completed, of which 13 were producers. There were 32 new wells under drill at the end of the month.

Michigan

COPPER

Calumet & Hecla—Twenty Chilean mills and about 40 Willey tables are in service, and in the course of about a month the complete regrinding mills will be ready to go into commission. At No. 10 shaft a decided improvement in the copper contents of the rock was encountered in the south drift from the 73d level. A continuation of this strike will not only be of benefit to this company, but will afford great possibilities for the Osceola. The southern portion of the property has carried but little copper.

Isle Royale—At the annual meeting of the stockholders the Calumet & Hecla interests entered the directorate. The following were elected: George A. Flagg, A. R. Agassiz, R. L. Agassiz, O. A. Shaw and C. N. King.

Mass—The same mineralized condition continues that was first exposed by means of the crosscut from the 17th level. This lode is entirely new and its further opening may mean much to this company. Drilling is under way from the upper levels of "A" shaft to cut this formation.

Atlantic—Sinking continues at this company's Section 16 shaft at a depth of about 2200 ft. Drifting and crosscutting from the shaft toward the north are under way from the various levels. The shattered and broken formation continues.

Ojibway—A crosscut has been started to cut the formation on the 800-ft. level of No. 2 shaft. No. 1 shaft is sinking close to this same level. This company will in all probability run a mill test during the coming summer, utilizing the Phenix mill which is now idle. The lode, so far, has more than come up to the expectations of the management.

IRON—GOGEIC RANGE

Seven diamond drills are at work in the Copps district, near Marenisco. This is in new territory, on the eastern end of the range.

IRON—MARQUETTE RANGE

Portland—Contractors have begun stripping at this mine near Michigamme, on the western end of the range, which is to be worked by steam shovel. The mine belongs to the Buffalo & Susquehanna Company. The ore is a rather low-grade non-bessemer, but can be cheaply worked.

IRON—MENOMINEE RANGE

M. A. Hanna & Co. have several diamond drills at work on sections 28 and 34, 46-33, a few miles north of Amasa, and west of the Hemlock. This is new territory, and if ore is found it will extend the western limit of the range.

Minnesota

IRON—MESABI RANGE

Adams—That part of the ground formerly mined from Nos. 1 and 2 shafts at Eveleth is being stripped for mining by steam shovel.

Kellogg—Arrangements have been completed to work actively at this mine. There is some ore on the stockpile already. The mine belongs to the New York State Steel Company.

Perkins—Stripping is well advanced on this property, two miles northeast of Aurora. It is owned by Joseph Sellwood.

Sparta—The town of Sparta is being moved or torn down, and the work of stripping will soon be begun. Prospecting showed a large orebody under the town. This property is being opened by the Oliver Iron Company.

Missouri

ZINC-LEAD DISTRICT

Silver Moon—This company has made its initial turn-in from its new mill with 40,000 lb. of jack and 18,000 lb. of lead.

Continental Zinc Company—The workings at Prosperity are still shut down and the company is installing new pumps to recover the ground lost by a cavein over the pumps.

Black Cat—This company, three miles west of Joplin, has completed a shaft to the sheet ground and will erect a 250-ton mill. B. H. Poindexter is manager.

Endeavor—The new mill of this company at Prosperity has been destroyed by fire.

Symmes—This company has struck rich ore in open ground on the Riesling land west of Joplin. Seven drill holes show the ore at from 62 to 84 ft. depth.

Joplin Separating Company—This company is enlarging its plant to handle a larger amount of ores containing an excess of iron.

Ruby Jack—This mine and lease have been sold to J. A. Wettich, of Nowata, Okla., for \$20,000. A 300-ton mill will be erected.

Pinnacle—This company at Oronogo has started its mill on its 42-acre lease. J. H. Tonkin, of Joplin, is manager.

Herald—This company, at Cave Springs, will install an electric hoist of large capacity at the incline shaft and is sinking a shaft from the upper to lower levels to facilitate loading the skips

Montana

BUTTE DISTRICT

Davis-Daly—A new vein has recently been intersected in the Colorado mine by the crosscut on the 1400-ft. level at a point about 400 ft. west of the shaft. Another vein was recently cut on the same level and showed a width of about 17 ft.

Both of these veins were located by means of diamond drilling, and a third, also located by that means, will not be reached for another month at least.

La France Company—Shipments from the Lexington mine have been stopped and the work confined to development. It is not known at what time the mine will resume shipments.

MISSOULA COUNTY

Saltese District—Work is being carried on with a large force of men at the Iron Mountain, where new machinery has been installed. The Carter properties are also in operation. The Swastika has recently made a shipment of copper ore. At the Iron Mask a large shoot of concentrating galena ore has been opened up, and a concentrator is being built. The Monitor, which has been in constant operation during the past winter, has been forced to discontinue work on account of the lack of wood for use in the boilers. Enough fuel has been reserved, however, to keep the pumps going and the workings free from water. As soon as the weather breaks a fresh supply of fuel will be secured and work resumed.

SILVER BOW COUNTY

Pittsmt—This mine is said to be developing well, and at present is yielding about 150 tons daily of first-class ore and 200 tons of second-class. The smelter, at present of 200 tons daily capacity, is being enlarged to 500 tons; probably the concentrating mill will be enlarged also. Plans are in hand for refinancing the company.

Nevada

CHURCHILL COUNTY—WONDER

Nevada Wonder—It is definitely decided that the company will erect its own mill, and J. B. Daniel is now in San Francisco with a view of securing bids on the material and machinery necessary for a 15-stamp mill.

ESMERALDA COUNTY—GOLDFIELD

Combination Fraction—This property is maintaining an average daily production of 90 tons of ore averaging \$40 per ton, in addition to some high-grade ore which is being shipped to the smelter.

Daisy—The daily production is about 10 tons, averaging from \$35 to \$40 per ton.

Goldfield Star Mining and Leasing Company—Walter Stopford has purchased Ernest Kennedy's interest, and has made arrangements to sink the vertical shaft, now 250 ft. deep, another 100 ft., and then crosscut for the orebody.

Goldfield Consolidated—Senator Nixon has disposed of his entire interest in this company, amounting to 308,000 shares, at a price of \$7.50 per share, according to the common report. His holdings were

purchased by George Wingfield and Bernard M. Baruch and associates. Net earnings of the company in March are said to have been \$950,000 against \$450,000 in February.

ESMERALDA COUNTY—LUNNING

Daniel E. Storms, B. F. Baker and L. K. Gregory are now building a cyanide plant to treat an old tailings pile about 10 miles west of Mina.

ESMERALDA COUNTY—RAWHIDE

Dromiae—This company, operating the old Bradshaw lease, made a shipment of 10 tons to the sampler at Hazen last week, returns from which show a net value of over \$400 per ton.

Bethania Mines, Incorporated—Daniles & Bridges, lessees, have opened up ore at a shallow depth, from which about a ton of high-grade ore is being sacked per day.

Gold Reef—This lease operating on the Bethania estate is working in a good grade of milling ore. The lessees are under contract to have a power hoist in operation by April 15, in which case they will be granted an extension of two years.

Marigold—This lease on the Coalition estate is reported as having opened some rich ore in a winze sunk from the 300-ft. level. The face of the north drift on the 130-ft. level shows 4 ft. of good ore. Daily shipments of about five tons are being maintained.

Rawhide Coalition—Victor lease is now being developed, but not much ore is being taken out, owing to the poor milling facilities. The Rawhide Truett lease continues to sack ore and make shipments to the different mills in Rawhide and Salt Lake City.

Golden Hour—This lease, on the Consolidated Mines estate, has the largest gallowes frame in the district, and expects to sink to a depth of 500 ft. Milling ore is being extracted.

Black Eagle—This property is now under bonds to Chicago mine operators for \$110,000.

Rawhide Western Railway—This company is now being financed in New York by its president, Charles Wesley Reed. He has taken an option for 90 days on the Rawhide Coalition and Rawhide Queen properties.

ESMERALDA COUNTY—STIMLER

Nevada Cottonwood—There are now six sets of leasers working on this property. Several are saving ore, and are doing systematic development work. Barnes & Collins, lessees, recently sent out an 18-ton shipment which returned \$78 per ton.

EUREKA COUNTY—EUREKA

Windfall—In the east crosscut on the 200-ft. level a body of high-grade lead-carbonate ore was recently encountered. The orebody has been penetrated 6 ft. with the wall not yet in sight and gives

high assays in gold, silver and lead. The ore-shoot is a new one and is entirely distinct from the main gold-bearing orebody being blocked out west of the shaft. A station is being cut at the 325-ft. level and crosscuts will be run at this depth to further prove the orebodies. The 200-ton mill will be completed May 15. A 50-h.p. hoist will replace the present 25-h.p. hoist.

HUMBOLDT COUNTY—SEVEN TROUGHS

Wihuja Lease—Another shipment will be made to the Kindergarten mill. Cross-cutting is being carried on from the 375-ft. level to explore the southern part of the holding. A winze is being sunk from the 275-ft. level for the purpose of an air connection with the 375-ft. level. The shaft will be put down an additional 100 ft. making it nearly 500 ft. on the incline.

Mozuma Hills—This property was closed down for two weeks on account of internal dissension in the company as to the proper method of development. Manager John Harnan is expected at the mine any day and it is reported that he will start a vertical working shaft which will be sunk to a depth of at least 600 feet.

LINCOLN COUNTY—INDIAN SPRINGS

Pioneer Oil—The machinery for drilling is now arriving and is being hauled to the seat of operations, about three miles from the station.

NYE COUNTY—BULLFROG

Crystal Bullfrog—Machinery for the construction of the mill has been received and the foundations are in place. At a late date the Bullfrog chamber of commerce called a meeting to endeavor to secure for Rhyolite the location of the mill instead of South Bullfrog as now proposed. The result of the conference has not yet been made public.

NYE COUNTY—HELENA

Broken Hills—W. H. Whitmore and Thomas G. Murphy, leasing on Block No. 4, made a shipment last week of 15 tons, the ore coming from a raise from the 70-ft. level.

New Mexico

GRANT COUNTY

Last Chance—Work has been resumed by the newly organized Sutton Consolidated Mining Company.

Viola—The Lordsburg Mining and Reduction Company is working this old mine. It is reported that a 100-ton concentrating plant will be built.

Penn—The property is best known as the Aberdeen. The Malachite shaft is being repaired in anticipation of sinking from the 367-ft. level to the 600, where crosscuts will be made.

Eighty-Five—Two carloads of ore are shipped weekly. The ore carries copper, silver and gold.

Clemmie—Returns from the first carload shipment of ore to the Douglas smelter gave \$30.40 per ton.

Buena Vista—J. H. Chamberlain is manager. Good ore is reported at the bottom of a 40-ft. shaft.

SOCORRO COUNTY

Mistletoe—A 50-ton dry concentrator is being built to treat zinc ore.

Oklahoma

According to the *Oil Investors' Journal*, petroleum production in Oklahoma in March was 3,504,609 bbl., 300,027 bbl. more than in February. Shipments in March were 3,159,414 bbl., and 345,195 bbl. were added to stocks. The total stocks of Oklahoma oil reported on March 31 were 54,356,947 bbl. In March 327 new wells were completed, of which 305 produced oil and four gas; while 18 were dry. There were 272 new wells in progress at the end of the month.

OTTAWA COUNTY

Miami-Yankee—This company has leased 18 acres of land from the Emma Gordon Company at Miami, and will develop it at once.

South Carolina

LANCASTER COUNTY

Haile Gold Mine—By order of the district court on April 2, Charles D. Jones, of Lancaster, S. C., and L. W. Amerman, of Bayonne, N. J., were appointed receivers for this company, and will at once resume operation of the mines. The application for a receivership was made by Harry S. Seeley, of New York, trustee for the bondholders, the bonded indebtedness of the company amounting to \$224,000. The mines were closed during the financial depression last year.

Tennessee

POLK COUNTY

Ducktown Sulphur Copper and Iron Company—It is expected that the first section of the sulphuric-acid plant will be completed about Sept. 1. The company is said to have contracted its acid for a period of five years at a price which will show a profit of more than 11 per cent. on the capital stock of the company, including the new issue.

Texas

The production of petroleum in the Southeast Texas district in March is estimated at 772,797 bbl., an increase of 1422 bbl. over February. Shipments by water were 270,477 bbl.; by rail 400,261; total, 671,738 bbl. During the month 54 new wells were completed, of which 36 were producers and 18 dry holes. There were 72 wells in progress at the end of the month.

Utah

JUAB COUNTY

Chief Consolidated—The stock of this company, which purchased the Little Chief and other properties, has recently been listed on the Boston curb. The capitalization is \$1,000,000 of which 692,030 shares of par value of \$1, each, have been issued.

Plutus—A 3-ft. vein of lead carbonate ore was recently encountered in the one of the old Tetro stopes near the Godiva lines.

May Day—This mine will soon be operating an additional depth of 200 ft., or a total depth of 1000 ft. At the recent annual meeting the old directorate was re-elected. The report shows that during the year 5218 tons of crude ore were sold, bringing \$83,192, and 1768 tons of concentrate, bringing \$44,026. The operating expenses for the year were \$86,410. Dividends were paid amounting to \$44,000.

Opohongo—A body of arsenical copper ore of shipping grade has been opened at a depth of about 700 ft. The work is being conducted from the 300-ft. level of the Black Jack mine.

Iron Blossom—An initial dividend of 8c. per share is announced payable April 25. The Colorado and Sioux Consolidated have also posted dividends of 8c. and 7c., respectively.

TOOELE COUNTY

Boston-Sunshine—The new cyanide mill has been started and it is expected that it will be running at full capacity as soon as the damage caused by a slight accident in the vacuum filter department is repaired.

Western Utah Copper—A crew of men has been taken to the properties near Gold in the Deep creek district where development will be continued under the direction of Sup. J. E. Bergh.

International Smelting and Refining Company—The price paid for the Raritan works is said to have been \$6,500,000. The earning capacity of the plant is said to be \$1,000,000 per annum. The company has so far issued \$10,000,000 of its capital, the remaining \$3,500,000 being for the construction of the Tooele smelter and working capital.

Virginia

MONTGOMERY COUNTY

Virginia Iron, Coal and Coke Company—The Laura furnace at Radford has resumed work.

Washington

OKANOGAN COUNTY

Penn-Wash—Fifty claims in the Mineral hill district, including properties controlled by the Washington Consolidated Copper Company, have been sold to

the Penn-Wash Consolidated Mines Company, composed of Pennsylvania and Minnesota people. President, William Baines.

SNODHOMISH COUNTY—SILVERTON

Dahl—J. Newhall has lately financed a company in London to develop this property upon which a strike of gold ore, reported to run \$80 per ton, was made two weeks ago.

Canada

BRITISH COLUMBIA—BOUNDARY

Dominion Copper Company—In the Supreme Court of British Columbia an order has been issued for the sale of those of this company's properties as were mortgaged by it to secure the bond issue. Justice Clement upheld the contention of the liquidator of the company and the unsecured creditors that the property acquired by the company after the mortgage had been given should not be included in the order for foreclosure and sale applied for by the National Trust Company, of Toronto, trustees for the bondholders. This decision of the court is expected to result in the unsecured creditors being eventually paid in full.

British Columbia Copper Company—The first payment of 10 per cent. has been made on a group of mineral claims in Wellington camp, bonded last September. Development work done during the six intervening months has shown the occurrence of ore in quantity and of good grade.

BRITISH COLUMBIA—NELSON

Eureka—L. B. Reynolds, manager, has obtained capital for further development of this property, situated on Eagle creek. Copper ore, with some gold and silver occurs in considerable quantity.

Silver King—Shipment of ore has been resumed, with an output of about 50 tons per day. The ore is conveyed to Nelson by aerial tramway, and thence about 50 miles to the Trail smelter by railway. The mine is under lease and bond to the Kootenay Development Syndicate, and Louis Pratt, of Nelson, is directing operations.

Second Relief—A syndicate of Wisconsin men has bonded the Second Relief gold-quartz mine, near Erie. There is a 10-stamp mill, mine and mill have been employing 25 to 30 men.

BRITISH COLUMBIA—PORTLAND CANAL

Portland Canal Mining Company—Financial arrangements have been made for the construction of an aerial ropeway from the group of claims on Glacier creek to Bear river, which flows into the Portland canal. A concentrating mill and water power plant are also provided for. C. H. Dickie, who is at the head of the enterprise, is conferring with W. J. Ehlenberg, of Spokane, Wash., who twice re-

ported on the property, as to class of equipment to be put in.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ended April 3 were: Buffalo, 55,520 lb.; Coniagas, 65,800; Crown Reserve, 123,476; Chambers-Ferland, 60,000; Kerr Lake, 55,040; La Rose, 260,070; McKinley-Darragh, 55,160; Nipissing, 218,090; O'Brien, 127,970; Right-of-Way, 119,800; Trethewey, 129,000; total, 1,270,826 pounds.

La Rose—Net earnings during the first quarter of 1908 are said to have averaged upward of \$75,000 per month.

QUEBEC

Amalgamated Asbestos Corporation, Ltd.—This company has been organized as a consolidation or combination of the principal asbestos mining concerns in Canada. The capital authorized includes \$10,000,000 in stock and \$15,000,000 in debentures, though not all of these will be issued at the present time. The mines included now produce about 80 per cent. of the Canadian output of asbestos, or over 70 per cent. of the world's supply. The companies named as entering into the consolidation are the Beaver Asbestos Company, the Bell Asbestos Mines, Ltd., the British Canadian Asbestos Company, the Dominion Asbestos Company, King's Asbestos Mines, Ltd., and the Standard Asbestos Company. Some smaller mines also will be taken in. The directors of the Amalgamated company are: Thomas McDougall, Quebec; Hugh A. Allan, E. B. Greenshields, Robert Mackay, William McMaster, Montreal; H. H. Melville, Henry M. Whitney, Boston; Richard V. Mattison, Ambler, Penn.; H. A. Berwind, Theodore W. Crump, C. Hartman Kuhn, Howard E. Mitchell, Philadelphia; James M. Beck, R. H. Martin, New York.

Mexico

BAJA CALIFORNIA

Boleo—The 1907 output was 24,530,000 lb. refined copper. When the Greene Cananea property shut down, this company secured many Greene laborers, as a result of which its operations were materially increased, and its production for 1908 is placed in excess of 30,000,000 pounds.

CHILICAHUA

Batopilas—The silver production for the first three months of the current year was, Jan., 210,500 oz.; Feb., 205,810 oz. and March, 114,200 oz. bullion.

Negrita Carmen—Walter MacLachlan, managing director of the San Francisco del Oro Mines, Ltd., closed a deal here this week for the purchase of the Negrita Carmen group of mines of 10 pertenencias in the Sta. Eulalia district, 15 miles from Parral.

COAHUILA

Mexican Coal and Coke—It is reported

that a coal bed 8 ft. thick has been penetrated at shaft No. 8.

SONORA

El Tigre—It is reported that the Lewisohn engineers will examine this property in the near future, with the view of purchasing the mine.

Nacozari District—An important copper deposit is reported as having been discovered by R. L. Van Dusen and Fritz Kohlmeier. It is 3 miles from Pilaes, and 500 ft. of development work has been done.

El Globo—It is reported that \$80,000 will be spent to install machinery to develop gold-bearing claims.

Barrigan—Telluride of gold has been found here. About 200 denouncements have been made.

Santa Fe—P. J. Tehaney has acquired this property. The ore carries gold and silver.

Santa Rosalia—Clancy Brothers have purchased this mine, and are equipping it with modern machinery.

Chispas—An 8-mile tramway was installed recently.

Belen—A body of bismuth-gold-silver-ore was opened a short time ago.

ZACATECAS

Zacatecas Smelter—A new 350-ton furnace was completed March 31. It will be supplied with ore from the Magistral Mining Company. The plant is said to have cost \$100,000, and is 4 miles north of Zacatecas.

Africa

NATAL

The report of the Mines Department for the year 1908 shows a gold production of 442 oz., or 436 oz. less than in 1907. Other productions were 10 tons of copper ore, 20 tons manganese ore, 3 tons graphite and 770 tons lime. Coal production was 1,600,774 tons, an increase of 133,731 tons. The coal was disposed of as follows: Exported overland, 100,242 tons; exported by sea, 446,915; sold to steamships, 710,777; used in colony, 405,840 tons. Labor employed in mines included 400 whites, 3310 East Indians and 4741 negroes; total, 8460. The number of persons killed in mining accidents was 93, and the number injured 87; the death rate per 1000 employed either above or below ground being 10.37 and the death or injury rate 20.08.

Peru

Cerro de Pasco—The enlargement of the smelting works has been completed, and on April 15 the output of the plant will be increased from 2,500,000 lb. of blister copper to 4,000,000 lb. per month. The company employs between 5000 and 6000 men.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, April 14—The coal trade in the West continues to show some improvement, the demand for steam coal apparently increasing as spring opens. The Steel Corporation has closed some large contracts for coal for its Gary plant, and other interests have also closed contracts for the year.

The Eastern bituminous trade shows a slight improvement, but is still rather quiet. Manufacturers have not recovered from the habit of buying for immediate needs, and seem to be still uncertain about the future.

The anthracite trade is quiet and steady, so far as current business is concerned. Of course, the chief topic of discussion in this trade is the possibility of a strike, and we are as far from knowing anything definite on this point as we were a week ago. Negotiations have halted and the future is entirely uncertain. A fuller statement of the situation in the anthracite field will be found on another page.

The Anthracite Coal Trust Case—The United States Circuit Court of Appeals has granted an extension of time until July 1 for the taking of testimony by the defendants in the Government suit against the companies in the alleged Anthracite trust.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to April 3, short tons:

	1908.	1909.	Changes.
Anthracite.....	1,306,946	1,284,300	D. 22,646
Bituminous.....	8,780,011	9,009,892	I. 219,881
Coke.....	1,847,418	2,70,164	I. 725,746
Total.....	11,934,375	12,994,356	I. 1,019,981

Total increase this year to date was 8.5 per cent.

Coal and coke tonnage, Chesapeake & Ohio railway, eight months from July 1 to Feb. 28, short tons:

	Coal.	Coke.	Total.
New River.....	4,285,613	162,380	4,447,993
Kanawha.....	3,424,734	19,879	3,444,613
Kentucky.....	236,428		236,428
Connecting lines.....	173,171	52,187	225,358
Total.....	8,119,946	234,396	8,354,342
Total, 1907-08.....	7,508,097	251,203	7,759,300

Deliveries this year to points west of mines, 4,247,117 tons coal and 137,584 coke; points east, 1,019,974 tons coal and 96,812 coke; tidewater, 2,846,888 tons coal; anthracite to line points, 5967 tons. Total increase in shipments this year, 595,042 tons, or 7.7 per cent.

Anthracite coal shipments in March were the largest ever reported, reaching a total of 6,332,474 long tons, an increase of 1,566,316 tons over March, 1908. For the three months ended March 31 the totals were, in long tons:

	1908.	1909.	Changes.
Reading.....	2,734,146	3,328,316	I. 594,170
Lehigh Valley.....	2,400,503	2,627,560	I. 227,057
N. J. Central.....	1,859,752	1,971,090	I. 111,338
Lackawanna.....	2,356,281	2,330,991	D. 25,290
Del. & Hudson.....	1,702,599	1,655,509	D. 46,990
Pennsylvania.....	1,428,504	1,429,888	I. 994
Erie.....	1,732,719	2,032,334	I. 299,615
N. Y., Ont. & West.....	679,659	736,334	I. 62,675
Total.....	14,888,253	16,091,823	I. 1,203,570

The total increase this year was 8.1 per cent. The Delaware & Hudson and the Delaware, Lackawanna & Western had small decreases; all the other companies made gains. The large March tonnage was due to the desire of the companies to accumulate stocks in case of a stoppage of work.

New York

ANTHRACITE

April 14—Current trade in the hard-coal market is good, dealers being inclined to put in stocks. There was a report that the April discount would be suspended owing to the strike situation, but no action of this kind has been taken. Prepared sizes are in good supply, but steam sizes are scarce.

Prices are \$4.25 for lump and \$4.50 for egg, stove and chestnut f.o.b. New York harbor points. For small steam sizes prices are nominally unchanged as follows: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@1.72; barley, \$1.35@1.50; all f.o.b. New York harbor points. Advances of 10 to 25c. are asked by commission merchants.

BITUMINOUS

The market continues irregular, business being done still in bunches, while shippers are unwilling to keep any considerable stocks at tide. Contracts continue to be closed slowly, and are not as generally coupled with immediate orders as is usually the case. The only feature this week has been some inquiry for off-shore business, especially for the West Indies and South America.

The far East has been quiet, but is showing some signs of waking up. The Sound is taking small but rather regular quantities. All-rail trade is still improving. Transportation is fully up to schedule and there is no question about car supply.

New York harbor trade is irregular,

customers apparently watching for bargains. Steam coals of fair grade can be had at \$2.40@2.50; better kinds at around \$2.60, and George's Creek at \$3@3.40, all f.o.b. New York harbor points. Gas coal has sold very low, 3/4-in. bringing 90@95c., run-of-mine, 70@75c. and slack 55@60c. all at mine.

The Coastwise vessel market is dull and captains are hunting for trade. Rates are very low as follows, for large vessels from Philadelphia: Boston, Salem and Portland, 60c.; Portsmouth, 65c.; Lynn, 65@70c.; Newburyport, 70c.; Providence and the Sound, 50c. per ton.

Birmingham

April 12—The coal-market conditions in Alabama continue quiet. The coke demand is a little improved and the larger iron concerns are accumulating stock for an emergency. The coal operations are as dull as they have ever been. Reductions in price have had no influence. A cargo of Alabama coal went from Pensacola, Fla., recently to Mexico, but a steady trade to that country is not anticipated. Coke prices are up a little and the output is somewhat better than it has been.

Chicago

April 12—The coal market continues quiet, with fine sizes strong, from Eastern and Western mines, and domestic in much less demand except for anthracite, sales of which at April are reported good. Recent cool weather has aided domestic sales a little, but lump is in general in lessening demand and should be shipped lightly to the Chicago market if demurrage sales are to be avoided. Under existing conditions Western coal is frequently sold for 10 or 20c. below its fair price because of overshipments. Steam coals are in steady demand, though the slow increase in consumption disappoints many dealers.

Contract making shows no great change from a year ago. Perhaps more large consumers are holding off in the hope of continued depression of prices and a satisfactory open market. The number of small- and medium-sized contracts entered into, however, is probably greater than a year ago. Contract prices are in general low.

Eastern coals are fairly firm, with the tendency of shippers to caution about overshipments continuing, especially with regard to smokeless. Hocking is still on the weak list, but is improving through

lessened shipments, the list price being cut 10 to 30c. Smokeless holds well up, lump bringing \$3.20@3.45, and run-of-mine \$3.05@3.15. Illinois and Indiana bring \$1.05@2.25 for lump, \$1.65@1.75 for run-of-mine and \$1.45@1.05 for screenings.

Cleveland

April 13—Better accounts come from the head of the Lakes. Coal is being taken from the docks there at a more rapid rate than for some time past, so that there is a prospect for storage room when the Lake trade opens. A few small cargoes have been loaded here, but not much will be done till ore begins to move.

Steam coal is rather quiet. The best demand is for slack, which is not in plentiful supply. This will probably be the case till Lake coal begins to come in large quantities, which will increase the quantity of slack made.

Pittsburg

April 13—A meeting of large producers of coal in this district is being arranged for the purpose of reestablishing firmly the prices of coal on the basis of \$1.15 for mine-run at the mine. Lately a number of contracts have been taken at \$1.10 and lower. Slack is quoted at 65c., but sales this week of fairly large tonnages were made at 55c. Lake shipments are increasing, but no shipments have been made to points in the Northwest. All shipments have been confined to ports on Lake Erie. It is estimated that production in the Pittsburg district this week is about 55 per cent. of normal. A number of large contracts have been taken and the tonnage this season promises to be greater by Lake than last season. The rivers were navigable for a few days but no coal was sent out. A number of empty barges and flats were brought up from southern ports and sent to the mines. All the river mines are in practically full operation.

Connellsville Coke—Conditions continue dull and prices low. Some sales of furnace coke said to be of an inferior quality are reported to have been made as low as \$1.35. The market for spot furnace coke is around \$1.50. Some producers are holding furnace coke for deliveries running to July 1 or Oct. 1 at \$1.75, but contracts covering requirements for the rest of the first half are being made at \$1.60. Foundry coke for spot shipment may be had at \$1.80@1.90 and on contract from \$1.90@2.10 at oven.

The *Courier* gives the production in both regions at 245,450 tons. The shipments were 9193 cars as follows: To Pittsburg district, 3496; to points west of Pittsburg, 4726; to points east of Connellsville, 971 cars.

Foreign Coal Trade

French Coal Consumption—The consumption of coal in France for the full year is officially estimated as below, in metric tons:

	1907.	1908.	Changes.
Production.....	36,753,627	37,622,556	I. 868,929
Imports.....	14,868,967	14,732,530	D. 136,437
Total.....	51,622,594	52,355,086	I. 732,492
Exports.....	1,163,286	1,092,310	D. 71,176
App. Cons.....	50,459,308	51,262,776	I. 803,668

In this estimate no allowance is made for stocks on hand, which did not vary greatly during the two years.

Transvaal Coal—Coal production in the Transvaal is officially reported at 2,883,342 tons in 1907, and 3,012,692 in 1908; an increase of 129,350 tons. This coal is practically all consumed at the gold mines and mills of the Witwatersrand.

Welsh Coal Prices—Messrs. Hull, Blyth, & Co., London and Cardiff, report current prices of coal as follows, on April 3: Best Welsh steam, \$3.54; seconds, \$3.42; thirds, \$3.30; dry coals, \$3.48; best Monmouthshire, \$3.12; seconds, \$3.06; best small steam, \$2.46; seconds, \$2.16. All per long ton. f.o.b. shipping port.

Iron Trade Review

New York, April 14—Notwithstanding the delays and cross currents in the tariff work at Washington, the iron and steel markets have been much stronger and more active than certain interests would like to have it supposed. Orders are coming forward quite liberally on several lines and many buyers seem to be realizing the advantage of the lower range of prices which has now been generally established.

In finished material the ordering of structural steel and the closing of building and fabricating contracts continue to furnish a large amount of business. A number of contracts have been concluded and others are pending, with a probability that they will be closed soon. New building projects are coming forward on rather a large scale, and the mills seem to be assured of a good amount of work for some time. Other lines are not quite as active, though much business has been done in bars and plates. Wire has rather lagged behind, owing to the general expectation that lower prices will be made by the leading interest, which has so far made very few concessions. The demand for nails and other iron work used in general building continues good.

The rail question is still unsettled and orders are generally held up, with the exception of a few small ones. It is understood that there will be sharp competition on some heavy orders for Canada and also upon some South American orders which are pending. The railroads are in the market for a good deal of bridge work and some equipment.

Pig iron is the weakest end of the market, but foundries are ordering more freely, especially in Seaboard and New England territory. Some furnaces are rather inclined to hold back in this business, being unwilling to take much at current prices, but others are meeting the market freely. Some transactions in basic pig are reported, but of moderate size.

Pig Iron Production—The reports of the blast furnaces, as collected by the *Iron Age* shows that on April 1 there were 224 coke and anthracite stacks in blast, having a total weekly capacity of 409,200 tons. This is a decrease of 9600 tons from the March report. Making allowance for charcoal furnaces, the production of pig iron in March was, approximately, 1,880,000 tons; for the three months ended March 31, it was 5,427,000 tons.

Baltimore

April 13—Exports for the week included 183,123 lb. spelter and 4,999,200 lb. steel billets to Great Britain; 2000 tons steel rails to Buenos Aires. Imports included 100 tons ferromanganese and 1000 tons manganese ore from Rotterdam; 3806 tons iron pyrites from Huelva, Spain; 5350 tons iron ore from Cuba.

Birmingham

April 12—The Southern pig-iron market shows improvement as to demand and some stiffening of price. The greater portion of the sales being made are at \$11 basis, No. 2 foundry, though some of the larger companies are holding for \$11.50. The production is being held up well. There is a little accumulation of iron to be noticed throughout this section. The foundries and machine shops have a little spurt on in their business and the cast-iron pipe makers are busy. The announcement is made that the American Radiator Company, of Chicago, has leased the little works of the Birmingham Pipe and Casting Company. There are rumors again of the shutting down of the steel plant at Ensley.

The announcement that Birmingham was now practically on a basis point for steel selling was a piece of cheering news. Heretofore all sales of steel by the Tennessee company have been on Pittsburg price, plus freight. There has been a demand for some time for a Birmingham basis for steel and the statement that it had been granted caused good feeling. There is plenty of room for improvement in the steel market.

Chicago

April 12—The pig-iron market shows some encouragement to furnacemen in a number of inquiries for large amounts of iron to be delivered in the second half of

the year, and an increased number of sales for current use by foundrymen generally. The average consumer of iron is still buying for the needs of 30 to 90 days in the future. Local producers of iron are holding firm to \$16@16.50 for Northern and find no temptations to cut prices as Southern interests have done, the demand for Northern being steady and chiefly for special uses.

Southern iron sells in general for \$11 Birmingham, or \$15.35 Chicago, with some contracts made at \$10.50, but a tendency to hold more firmly than formerly to \$11 as the bottom price. A number of large contracts are said to be hovering about the \$11 mark with a prospect of their being closed at once on any decided tendency of the market to improve. Everything dependent on agricultural interests shows prospective need of a large tonnage of iron in the last half of the year.

Cleveland

April 13—The first long contract of the season has been closed and is at 65c. per ton from Duluth to a Lake Erie port. The price question for the season is still unsettled, and no ore is being sold.

Pig Iron—Sales have been in small lots only, and contract iron is being taken slowly. On new sales the price is on the basis of \$15@15.25 for No. 2 foundry.

Finished Material—There is a good deal of inquiry for steel bars. A number of structural contracts are under negotiation, and a few have been closed. There is a demand for sheets in small lots.

Philadelphia

April 14—There is no perceptible change in the pig-iron situation. Several good sized orders have been placed for future delivery, Southern furnaces having secured the business. There is very little disposition to buy even at present low prices. Iron is accumulating at several furnaces. Buyers look for further shading because of outside competition. Basic has not weakened; agents of makers say no further shading is probable. About the same volume of foundry work is being turned out and the demand for forge iron is at a low ebb.

Steel Billets—No sales have been definitely closed this week.

Bars—The mill output has not increased during April. Hardware material and all material entering into it are more active in consequence of increasing building activity.

Structural Material—Large requirements are before the trade and bids will be submitted this week. Quite a number of orders for a few hundred tons each have been placed.

Scrap—No business has been done outside of the usual small sales. The large dealers are keeping a close watch on cer-

tain holders of large quantities of scrap. The dealers want to be well stocked with cheap scrap when the upward turn comes.

Pittsburg

April 13—More new business has been booked during the past week than in a similar period since the opening of the year, chiefly, however, in small tonnages. The outlook is regarded as greatly improved. There is considerable new business pending, but is held back in anticipation of more favorable prices and also until the new tariff measure is definitely settled. The greatest activity is in the Youngstown district where practically every manufacturing plant is in operation, some at capacity.

The Ohio works of the Carnegie Steel Company are running almost at capacity. In this district the Carnegie company has increased production to a certain extent at its Homestead and Duquesne plants, but the Edgar Thomson rail mills are not running more than one-third. The company is operating 26 of its 59 blast furnaces and its general operations are something over 60 per cent.

An announcement of a stiff reduction in wire prices is likely to be ordered by the American Steel and Wire Company within the next few days. It has developed that one producing interest has cut the price, not openly, however, of nails 15c. a keg and plain wire about \$2 a ton. In merchant pipe trade has been entirely satisfactory for a dull period. The Southern Pacific likely will close in a short time for about 200 miles of 8-in. pipe and the Busch-Everett Syndicate for 260 miles of pipe for a line from its gas wells near Shreveport, La., to New Orleans. Structural-steel trade is dull and prices are so low that large concerns refuse to accept some of the business offered. There are a number of good tonnages being held up on account of failure to reach terms on prices. The tinsplate trade continues active and the leading interest is still operating 202 of its 213 active mills.

Pig Iron—There is absolutely nothing doing. The only inquiry in over a week was for 1000 tons of basic iron for the United Steel Company, of Canton, O. Valley furnaces bid \$14.50, but did not get it, the order going to a Canal Dover furnace which has a 40c. freight rate, while the Valley rate is 90c. The price is said to be \$15, delivered. Quotations are about as follows, but not based on actual transactions: Standard bessemer, \$14.75@15; malleable bessemer, basic and No. 2 foundry, \$14.25@14.50, and gray forge, \$13.25, all at Valley furnaces.

Steel—No sales of billets at the market price of \$23, Pittsburg; some billets have been sold on sliding-scale contracts. Sheet bars and tinsplate bars are still quoted at \$25.50 delivered. Merchant-steel bars are being sold on contract up

to Jan. 1 at 1.20c. and on all material ordered now and taken out before July 1 a concession of 5c. per 100 lb. is made. Plates remain at 1.30c., but this has been shaded.

Sheets—The sheet trade shows some improvement and prices are being maintained. Black sheets are quoted at 2.30c. and galvanized at 3.30c. for No. 28 gauge.

Ferro-Manganese—The market is quiet, but prices firm at \$43.50@44. Pittsburg.

Foreign Iron Trade

The production of steel in Germany for the year 1908 is reported as follows, in metric tons:

	Acid.	Basic.	Total.
Converter ingots.....	374,100	6,510,734	6,884,834
Open-hearth ingots.....	146,768	3,854,155	4,000,923
Direct castings.....	77,443	115,440	192,883
Crucible steel.....	88,183		88,183
Electric steel.....	19,536		19,536
Total.....	706,030	10,480,349	11,186,379
Total, 1907.....	685,161	11,378,471	12,063,632

The decrease in 1908 was 877,253 tons, or 7.8 per cent. Acid steel was 6.3 per cent. of the total in 1908, and basic 93.7; against 5.7 and 94.3 per cent., respectively, in the previous year.

German Iron Production—The German Iron and Steel Union reports pig-iron production in February at 949,667 metric tons, being 72,054 tons less than in January. For the two months ended Feb. 28 the make was, in metric tons:

	1908.	1909.	Changes
Foundry iron.....	383,652	376,554	D. 7,098
Forge iron.....	116,944	114,732	D. 2,212
Steel pig.....	177,253	182,067	I. 4,814
Bessemer pig.....	76,243	72,671	D. 3,572
Thomas(basic)pig.....	1,301,423	1,226,364	D. 76,059
Total.....	2,055,516	1,971,388	D. 84,127

Total decrease this year, 4.1 per cent. Steel pig includes spiegeleisen, ferro-manganese, ferrosilicon and all similar alloys.

Metal Market

New York, April 14—The metal markets generally are still inclined to be quiet, but show rather more strength in some directions.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Feb. 1909.....	\$ 8,869,814	\$ 3,676,413	Exp. \$5,284,401
" 1908.....	1,967,697	2,847,133	Imp. 879,636
Year 1909.....	16,726,170	6,996,596	Exp. 9,729,674
" 1908.....	2,411,797	13,646,617	Imp. 11,234,820
Silver:			
Feb. 1909.....	4,852,649	3,508,881	Exp. 1,343,668
" 1908.....	4,108,774	3,451,766	" 667,019
Year 1909.....	9,394,643	7,173,633	" 2,221,020
" 1908.....	8,256,918	7,079,622	" 1,186,296

Exports from the port of New York, week ended April 10: Gold, \$525,000, chiefly to Argentina; silver, \$1,116,655, principally to London. Imports: Gold, \$114,103; silver, \$73,402, both from Central and South America.

So far this year this the United States Mint has bought only 450,000 oz. of silver, all in January. The purchases and prices were: 125,000 oz., at 51.734c.; 100,000 at 52.096c.; 125,000 at 51.882c.; 100,000 at 51.920c. The average price was 52.133c. for the whole quantity.

Gold and silver movement in Great Britain, two months ended Feb. 28:

	Imports.	Exports.	Excess.
Gold, 1908.....	£ 7,976,765	£ 8,458,778	Exp. £ 482,013
Gold, 1907.....	7,972,149	6,580,042	Imp. 792,107
Silver, 1908.....	2,105,465	2,330,456	Imp. 65,000
Silver, 1907.....	1,507,664	2,643,964	Exp. 1,136,300

Of the silver imports this year a total of £1,886,323 is credited to the United

Gold—The price of gold on the open market in London continues unchanged at 77s. 9d. per oz. for bars and 76s. 4d. for American coin. There is no pressure to secure gold, and most of that arriving has gone to Austria and Germany. In New York an additional \$1,000,000 has been shipped to Argentina on London account, but none has gone to Europe.

Platinum—Business is reported to be a little better, demand being apparently on the increase. Dealers' prices are unchanged at \$23@24 per oz. for refined platinum, \$20 for hard metal and \$19@21 for scrap.

Our St. Petersburg correspondent writes under date of April 1 that business is dull. At Ekaterinburg crude platinum, 83 per cent., is quoted at 5 rubles per zolotnik—\$18.87 per troy ounce. At St. Petersburg prices are lower, 10,500@10,600 rubles per pood—an average of \$10.13 per ounce. The financial embarrassment of Prince Demidoff may lessen the offers of platinum on the market.

Silver—The market has been steady the past week on buying by the China banks, and closes strong at 239/16d. in London.

SILVER AND STERLING EXCHANGE

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, banks, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—More business, both for domestic consumption and export, has been done during the past week. Manufacturers report a steady increase in their orders and it is evident that the consumption of copper is creeping up. The demand has been met freely by the selling agencies and the market closes unchanged at 12 $\frac{1}{2}$ @13c. for Lake copper; 12 $\frac{1}{2}$ @12 $\frac{1}{2}$ c. for electrolytic in ingots, cakes and wirebars. The average of the week for casting copper has been 12 $\frac{1}{2}$ @12 $\frac{1}{2}$ cents.

Copper sheets are 16 $\frac{1}{2}$ c. base for large lots. Full extras are charged, and higher prices—up to 18c.—for smaller quantities. Copper wire, 14 $\frac{1}{2}$ c. base, carload lots at mill.

Owing to the Easter holidays, there was only three days' business in the London market since our last report, during which the market was strong and advancing. It closes at £57 12s. 6d. for spot, £58 6s. 3d. for three months.

Refined and manufactured sorts we quote: English tough, £62; best selected, £61@62; strong sheets, £73@75.

The statement of the Copper Producers' Association for March, and the figures for the three months ended March 31, are as follows, in pounds:

	March.	Three Months.
Stocks in U. S. March 1 and Jan. 1	173,284,218	122,357,266
Production for period	117,058,661	332,894,678
Total supplies	290,342,909	455,251,944
Deliveries, consumption and export	108,063,007	272,972,012
Stocks, April 1	182,279,902	182,279,902

The increase in stocks during March was 8,995,654 lb.; during the three months it was 5,022,630 lb. As exports were approximately 47,400,000 lb. in March and 1,20,253,000 lb. for the three months, the deliveries for consumption would be 60,663,007 lb. and 143,710,012 lb. for the two periods, respectively.

Exports of copper from New York and Philadelphia for the week, 6718 long tons. Our special correspondent gives the exports from Baltimore at 516 tons copper.

Imports and exports of copper in Germany, two months ended Feb. 28, metric tons:

	1908.	1909.	Changes.
Imports.....	29,817	23,207	D. 6,610
Exports.....	1,413	1,987	D. 326
Excess, imports.....	28,404	22,120	D. 6,284

Of the imports this year 21,660 tons were from the United States.

Tin—On account of the intervening holidays the London market was rather dull, but firm. Quotations close at £133 5s. for spot, £134 7s. 6d. for three months.

The domestic market shows no new features, business still being confined among dealers and traders. Spot tin can be bought at the close at about 29 $\frac{1}{2}$ c. per pound.

Supplies of tin in March are reported by A. Strauss & Co., London, at 6082 long tons, consumption, 7270 tons; visible stocks on April 1 were 10,715 tons, or 1197 tons less than on March 1.

The suit of Th. Goldschmidt against the Vulcan Detinning Company, for alleged infringement of patent on the process for removing tin from tinplate scrap has been withdrawn, having been settled out of court, on terms not made public.

Lead—There has been a good business done in this metal at somewhat higher prices and the market closes at 4.15 New York, 4.05 St. Louis.

The London market has been quiet during the week and prices have eased off. Spanish lead being quoted £13 5s., English £13 7s. 6d. per ton.

Spelter—There was a considerable business done at advancing prices. Stocks in the hands of smelters are decreasing and in view of the proposed tariff changes, they are not disposed to press sales. The market has advanced to 4.82 $\frac{1}{2}$ @4.85c., St. Louis, 4.97 $\frac{1}{2}$ @4.95c. New York.

New York quotations for spelter, April 8, was 4.82 $\frac{1}{2}$ @4.85c.; 9 and 10, 4.85@4.87 $\frac{1}{2}$ c.; 12, 4.87 $\frac{1}{2}$ @4.92 $\frac{1}{2}$ c.; 13 and 14, 4.97 $\frac{1}{2}$ @5 cents.

The London market is firm, good ordinaries being quoted at £21 10s., specials at £21 15s. per ton.

Base price of sheet zinc is now 63 $\frac{1}{2}$ c. per lb., f.o.b. La Salle-Peru, Ill., less 8 per cent. discount.

New York Metal Exchange—The quotations committees for the coming year are as follows: Copper, R. Hoehschild, L. Vogelstein, H. W. Hendricks, Paul Koning, W. P. Todd. Tin, Paul Koning, E. Baerwald, A. B. Hall, E. A. Caswell, Edwin Groves. Lead, R. Hoehschild, J. H. Lang, Frederick Steiner. Spelter, L. Vogelstein, R. Hoehschild, R. Elkan.

Other Metals

Antimony—Prices unchanged at 8c. per lb. for Cookson's, 7½c. for Hallett's and 7½c. for ordinary brands. There is some discussion over the duty of 1½c. per lb. proposed in the new tariff bill, and business is rather in suspense.

Aluminum—No change. No. 1 ingots are 22@24c. base. Wire, 31@32c. base, and sheets, 33@34c. base.

Quicksilver—The market is quiet, with only a moderate business doing. New York prices are unchanged at \$45@40 per flask of 75 lb. San Francisco, nominal at \$44@45 for domestic orders and \$42@43 for export. The reported reduction in London was not made; the price is still £8 7s. 6d. per flask, but 5s. less is quoted by jobbers.

Nickel—Large lots, contract business, 40@45c. per lb. Retail, spot, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. The price for electrolytic is 5c. higher.

Cadmium—Current quotation 75c. per lb., in 100-lb. lots, at Cleveland, Ohio.

Magnesium—Quotations for this metal are \$1.25 per lb., New York, in 100-lb. lots; for 5-lb. lots, \$1.40 per pound.

Zinc and Lead Ore Markets

Platerville, Wis., April 10—This week \$39.50 was the highest price paid for zinc ore; the base price was \$38 per ton of 60-per cent. zinc. A base of \$50 was paid for 80-per cent. lead; one choice car brought \$53 per ton.

SHIPMENTS, WEEK ENDED APRIL 10.

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.

Total	1,918,940	151,700	141,700
Year to April 10	28,160,874	779,280	2,371,550

In addition to the above there was shipped to the American Zinc Ore Separating Company 303,200 lb., and to the Joplin Separator Works 437,000 lb. zinc concentrates.

Joplin, Mo., April 10—On a base price of \$38 per ton of 60-per cent. zinc the highest price paid for sulphide ore was \$41, the base ranging down to \$36. The market was no stronger, ore selling at \$36 @38 base, same as previous week. Zinc silicate sold on a base of \$17@19, with the high price at \$22. The average price of zinc ore, all grades, was \$35.70. An enormous demand developed for lead ore, the St. Louis Smelting and Refining Company purchasing several of the large bins that have been accumulating for months. The

base price was \$54@54.50 per ton of 80-per cent. lead, and some ore is said to have sold as high as \$56. The average price, all grades, was \$54.32 per ton.

Zinc prices averaged higher on account of the small amount of silicate shipped compared to the previous week. The general shipment was a decrease of 1011 tons. In lead the shipment was increased 534 tons.

NOTE.—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

Chemicals

New York, April 14—The chemical market is dull and prices are practically stationary.

Copper Sulphate—There is a little activity in this line, but prices hold at \$4.60 per 100 lb. in carload lots and \$4.85 per 100 lb. in smaller quantities.

Arsenic—Owing probably to the large stocks on hand, prices hold low at 2½c. per lb. for white arsenic.

Nitrate of Soda—Spot and futures are both quoted at 2.15c. The market is dead for the present.

A despatch from Santiago, Chile, says that at a meeting held in Iquique to consider the continuation of the present combination of nitrate producers, a majority voted against it. This means the breaking up of the present agreement for limiting and apportioning production, so that

each producer will be free to mine and sell nitrate as it can.

Sulphur—Messrs. Emil Fog & Sons write from Catania, Sicily, under date of March 26: "Eighty of the smallest mines—those worked by the most primitive methods, the ore being carried on the shoulders of men—have been closed during the year, thus reducing the total number working to 500. Of big mines producing over 10,000 tons there are only six, which are responsible for about one-third of the total production. The remainder are by no means in a flourishing condition, and a strict enforcement of the law now in force prohibiting the employment of boys for the carrying of the ore would compel many of them to close down. It will, therefore, be seen that the much debated proposal to reduce the production could be carried out without much difficulty. Another matter which awaits attention is that of the disposal of the stocks which were taken over from the Anglo-Sicilian Sulphur Company. Apart from the expense of storing, interest, renewal and even increase of the government mortgages, one must take into consideration that the sulphur will not improve in quality by keeping it in the open for some years exposed to the rain and dust.

"The members of the Consorzio in Palermo having disagreed among themselves, the ministers in Rome dismissed the board and sent down a commissioner to take over matters.

"The erection of a large American refinery at Marseilles is nearing completion, and in the course of three or four months this new competition will have to be reckoned with. That some arrangement will be necessary with Mr. Frasch is very apparent. His representative is already in Rome discussing the matter, and we think one may take it that the formation of a sulphur trust is but a matter of time."

Mining Stocks

New York, April 14—The week on the Stock Exchange has been a short one, being broken by a two-day holiday. The Exchange adjourned from Thursday over to Monday. In London Monday was a holiday also, which was a matter of some importance in view of the recent large buying of American securities there. Notwithstanding this break, the market had been generally strong and there has been little or no interruption to the bull movement, to which reference was made last week. On the open days sales were large and prices showed a tendency to advance.

On the Curb trading was good, but not to any unusual extent. The copper stocks were moderately in demand, but with no special large selling movement. Cobalt stocks continued in demand at good prices. The excitement of the week was a break in Rawhide Consolidated, a stock which has been quiet for some time. It was

brought out again this week and was hammered down to a pretty low point on large sales.

Boston, April 13—The mining-share market has backed and filled, and the net results are general declines in the week's time. Activity has been in spots and in some cases drives have precipitated sharp declines. The two days' holiday period caused advances to carry over the week end, but outside of Amalgamated they have not held. Utah Consolidated broke \$3 to \$3.75 on persistent bear selling. There seems to be a strong bear clique in this specialty which manifests itself from time to time. United States Smelt-ing common has been a weak spot and a low price was made today at \$39.50, a decline of over \$2.

The report of the Copper Producers' Association was at first construed favorably, but later was used as a bear argument. Amalgamated showed good action last week, but weakened after the holiday. Arizona Commercial has been a strong spot, but closes with a net loss of \$1.75 at \$41.50. Mass Consolidated has furnished a strong market, the price reaching \$9.37½ today.

Kerr Lake Mining has been taken from the Curb and placed on the unlisted department of the Exchange. It is worthy of mention that Kerr Lake is the first Cobalt mining company to be so listed. Two new stocks have been admitted to Curb dealings, Chief Consolidated, an Arizona company, and Inspiration, a Cobalt company.

Development of Dredges for Placer Deposits

Size of Buckets Has Increased from 3 Cu.Ft. to 13 1-2 Cu.Ft. in Favorable Gravel. Buckets of 8 Cu.Ft. Capacity Most Common

BY GEORGE B. MASSEY, II *

The gold dredge has taken from placer mining much of the glamour which has surrounded it, but it has elevated it from a haphazard calling of the more adventurous spirits to an industry which demands technical and systematic attention. For the last 25 years the dredge has been

were built in the United States and used in California. As they were found to be too light for the work attempted, development commenced. Much of this development was ill-advised, as the great number of unsuccessful dredges throughout the West will bear witness.

per of the screening and washing apparatus. The trouble experienced was that the dipper deposited large amounts at irregular intervals and so made washing difficult and irregular and also that the water and most of the gold would run out of the crack around the door. No prac-

GOLD DREDGE AT WORK ON BONANZA CREEK, YUKON TERRITORY

undergoing a process of evolution, and it is only within about six years that it has attained the excellence which enables it at the present moment to claim the interest of the investing public.

The first gold dredges were built in New Zealand. They were small, light machines, with inadequate power and of little capacity. Their owners were content with a very small interest on their investment. In the course of time some

TWO TYPES OF DREDGES ABANDONED

Two distinct types have been tried and definitely abandoned. One of these is the dipper dredge which has a crane or boom extending over the bow and carrying a long handle at the end of which is a large dipper. The boom may be revolved and the dipper can excavate all of the material immediately in front of the dredge. The bottom of the dipper is closed by a door which is opened when it is desired to dump the excavated material into the hop-

per means of preventing this have been found.

The other type abandoned was the hydraulic dredge. In this device the water, gravel and gold are sucked up a pipe by a centrifugal pump and discharged into the washing apparatus. But as gold is many times heavier than either gravel or water, it naturally had a tendency to remain where it was while the gravel and water were elevated. This was invariably found to be the case.

*50 Church street, New York City.

THE CHAIN-BUCKET DREDGE

The elevator dredge, or chain-bucket dredge as it is sometimes called, has an endless chain of buckets carried on a long, steel ladder extending from above the hopper on the dredge down into the water. As the chain is pulled upward each bucket slowly fills with gravel and water, all of which is elevated—each bucket being watertight—to the hopper where, in turning to go down again the buckets are inverted one after the other over the hopper, and deliver practically a steady stream of material to the washing apparatus.

Gold will settle very readily in the gravel when it is agitated, but the action of the buckets in filling is so quiet

gravel handled, as the larger output is obtained with practically no increase in labor cost. A 5-ft. dredge is often installed on a placer property to start operations and this followed with 7½-ft. dredges.

OPERATING CONDITIONS SEVERE

It may be safely said that no machinery is called upon to operate under more trying conditions than are present in placer dredging. The gravel, sand and water form an ideal wearing mixture which cuts in a short time anything but the very best of material. Repairs have to be made constantly to offset this action and they form a large part of the total cost of operation. The question resolves itself

more cheaply than it is possible to do elsewhere. The reason for this is that the gravel is somewhat easier to dig and wash than the average encountered in most other districts; in addition, there are in each case several dredges under one superintendent so that the office expenses, superintendence and other fixed charges are less per dredge. Other features which tend toward cheapness are the low-priced electric power and the excellent labor obtainable. There are so many dredgemen who live in the vicinity that the wages are much less than the same men would demand in most other localities.

In almost every prospectus of gold-dredging companies in which the public

SLUICES AT STERN OF A 13 FOOT DREDGE

THE TAILINGS STACKER

and steady that the gold has no chance to settle or get away. The elevator dredge is, therefore, acknowledged as the only satisfactory type for working placer ground. The size of a dredge is given by stating the capacity of each bucket in cubic feet. Seven years ago the most successful dredges had at that time buckets of 3 cu.ft. capacity. They soon gave way to the 5-ft. machine, while at present the dredges with 7½- and 8-ft. buckets are found in greatest numbers. There are two dredges near Folsom, Cal., which have 13½-ft. buckets that are working successfully in a loose gravel which digs easily.

Speaking in a general way, the larger the dredge the less the cost per yard of

not into avoiding repairs, but into keeping them as low as possible in comparison with the amount of material excavated. Breakage is avoided by using only the best machinery and material obtainable.

The first cost of a dredge is small, when compared with the cost of repairs where inferior machinery is used, and it should not form an obstacle in the way of purchasing the best machinery on the market. The best dredges now built will run 21 hours per day out of the possible 24. The three hours lost time are due to repairs and the periodical "clean-up" of the gold.

LOW DREDGING COSTS IN CALIFORNIA

The dredges in California are operating

is asked to join, the California costs are given as average dredging costs. This is far from being the case and is extremely misleading. In the tropics the labor cost may easily be twice that in California, and the fuel cost greatly in excess on account of procuring fuel and putting it on board the dredge. The chances are, too, that the best men cannot be obtained and the poorer labor used results in more expensive repairs to the machinery. In other localities it is impossible to work all the year round and the shorter season reduces the yardage and makes the overhead charges per yard greater. In countries like Alaska and Yukon Territory, it is necessary to thaw the frozen ground be-

fore the dredge can dig it at all. In Burma the season of rain precludes dredging for many weeks each year.

THE DREDGE CREW

In addition to a superintendent, who may attend to several dredges, the crew on each dredge consists of a dredge captain and an "extra man," as he is known in California, who is capable of taking the place of the captain, or of any of the other men who may be off. They work usually 10 hours. The dredging day is 24 hours, divided into three shifts of eight hours each. On each shift is a winchman who occupies the "pilot house" or winch room, where are located levers to enable him to absolutely control every movement of the dredge. There is also an oiler on each shift who looks after the lubrication and the flow of water.

If the dredge is steam-driven a fireman must be added to each shift. In addition to the above, it is necessary to have two deck hands, who work 10 hours during daylight shifting the electric-power cables, grubbing in front of the dredge, planting "dead men" to which to fasten the swinging lines, building dikes to keep the pond level at the proper height, assisting in making repairs and, if a steam-driven dredge, procuring fuel and putting in on board the dredge.

The wages of these men in California are: Captain, \$125 per month; extra man, \$3.25 per day; winchmen, \$3 per day; oiler, \$2.50; deck hands, \$2.50. As a rule, this does not include board or lodging, the men "finding" themselves. Often a bonus is given for good yardage. Logs are as carefully kept as in the engine room of a battleship, with meters to show the amount of power used, and an explanation for each minute of shutdown. The ground is surveyed in front of the dredge and the area worked is put down. A recording device is also in use which records the depth of digging for every moment. In this way the exact yardage is computed.

It is the custom to shut a dredge down for a half day every two weeks to "clean up." This is done by two men who do not usually belong to the crew. The material on the gold-saving tables is washed in a small sluice and the gold recovered. It may not occur to the average reader that a man may be about the dredges for weeks without so much as seeing a "color," since for every pound of gold recovered about 6,000,000 lb. of sand and gravel have to be handled.

TREATMENT OF THE GRAVEL

After the dredged material is dumped from the buckets into the hopper it passes into a revolving screen, or over shaking screens with holes varying from $\frac{1}{4}$ to $\frac{3}{4}$ in. The water for washing is sprayed under pressure on the material as it passes over the holes in the screens. The water, gold, sand and small pebbles pass through the holes and down over the large area of

gold-saving tables where the gold is caught and the water and sand pass on to the stern of the dredge where they flow back into the pond. The larger pebbles and boulders which could not pass through the holes are discharged at the lower end of the screens on an endless rubber belt which is carried on the tailings-stacker frame. This conveys the large material astern and upward to a sufficient height to allow of the disposal of all the material the dredge digs without crowding in upon the stern of the dredge.

The tailings as stacked have a natural slope of about 35 deg. from the horizontal, while the maximum angle at which gravel can be carried up the belt is about half that angle. The water used is furnished by centrifugal pumps of the proper size and speed to deliver the required quantity of water at sufficient head to thor-

BOW OF 13-FOOT DREDGE

oughly disintegrate the dredged material and carry it over the tables.

A large amount of experience is essential in the designing of a well balanced dredge. It involves a complete knowledge of the requirements of the case from both a theoretical and a practical standpoint, and the latter point of view can only be had from a critical examination of the dredges in operation.

Experiments with Broken Hill ore are to be made by Dr. Gustav de Laval, at London, using his cyclone process. The experimental plant to be installed there will also be used for testing ores from other parts of the world.

Since the discovery of chrome ore in Beluchistan in 1903, at least 19 small mines have been developed yielding, according to *l'Echo des Mines*, an annual output of 7000 tons.

Gold Mining in the Transvaal

SPECIAL CORRESPONDENCE

At the annual meeting of the Chamber of Mines, J. J. S. Langerman, of the Robinson group, was elected president in succession to Lionel Phillips. In moving the adoption of the report for 1908, Mr. Phillips said that the year had been marked by extraordinary progress in the gold industry. Never before were the prospects so bright or so stable. He congratulated the industry on the undoubted development of the native labor supply. The output for 1908 rose over two and one-half millions, bringing the total output of gold in the Transvaal since 1884 to £227,084,385. With the exception of £11,360,000, the whole had been produced on the Witwatersrand. The number of tons crushed exceeded those in 1907 by 2,670,000. Dividends had increased by £1,659,670. The total dividends paid by the Transvaal gold mines up to 1908 had amounted to £55,041,587. The profits earned by the producing companies equaled a distribution of 8.79 per cent. on the market value of the shares on Dec. 31, 1908.

The Transvaal in 1908 contributed 34 per cent. of the world's output of gold. The profit per ton milled by all the companies exceeded that in 1907 by 2d., despite the deliberate milling of ore with 2s. 7d. less per ton, hence the working costs had fallen by 2s. 9d. per ton. Owing to a fall of 2s. 4d. per ton in the working cost of sixty-seven of the principal producing mines, these had been enabled to include in their total reserves of payable ore an additional 5,400,000 tons, an increase of 9 per cent., though there was still room for a very considerable farther reduction.

Mr. Phillips emphasized the point that the lower the working cost, the longer was the life of the industry. The development of many of the deep mines during the past year had given such encouraging results that most of the engineers were of opinion that no appreciable diminution in the average yield, down to the present depths, need be predicted. The immense life of the industry was due to the slow rate of increase in the temperature of the earth, only 1 deg. F. being registered for every 255 ft. in depth. At this rate only 92 deg. would be attained at a depth of 7000 ft. vertical, being a much greater depth than any reached in the mining world.

Dealing with the expansion for 1909, he said it was probable that the amount of ore crushed would exceed that in 1908 by 3,500,000 tons. He contemplated an increase in the crushing capacity of the machinery of over 5,000,000 tons per annum.

An Electrically Operated Suspended Railway

BY ALFRED GRADENWITZ*

An interesting suspended railway operated by electric power was recently installed for the blast furnaces of a Belgian metallurgical works. This installation is especially remarkable for the configura-

On each trip about 15,000 kg. (33,100 lb.) of various iron ores are to be transported from the ore bin to the mixing hoppers. It was decided to use trains made up of a number of suspended cars, the motive power to be supplied from an electric locomotive equipped with a motor of 25 horsepower. This locomotive, a good view of which is shown in Fig. 3, is provided with a complete electrical equipment similar to

the motor to be fully utilized, the tractive weight of the locomotive is raised to about six tons by the addition of artificial ballast.

The driving wheels of the locomotive and the wheels of the car trucks run upon the lower flange of an I-beam, 500 mm. in height (19.7 ft.). The lower level of this I-beam is 2.555 m. above the ground. The running rails are fixed on brackets attached to the ore bins or buildings. Wherever such brackets could not be fitted to the walls of the neighboring building, independent bents of structural steel have been provided. In view of the heavy loads, all switches were designed as stub shifting switches, running on idlers like traveling platforms, and having one rail curved and the other straight to connect with the curved or straight sections of the track. These switches, which are illustrated in Fig. 2, are operated from the ground by means of chains acting on the shifting mechanism of the platform.

The cars of the suspended railway are of various designs, according to the requirements of the works, their contents varying between 600 to 1800 liters (21.2 to 63.6 cu.ft.) Those cars which have a capacity of over 1200 liters (42.3 cu.ft.) are self-discharging trucks, the ore being discharged through valves in the bottoms, which are unlocked at destination by the

tion of the tracks and for the exceptional weights of the loads to be handled on an industrial railway of this type. As the track winds about the plant it is made up almost entirely of a number of curves, only a few sections being on straight lines. The shortest radius of these curves being 7 meters, the train frequently describes a complete semi circle.

*Regensburgerstrasse 3, Berlin, W. 50, Germany

that of any electric locomotive running on the ground, viz., controllers, fuses, substantial brakes, sanders, etc. Having no grounded rail the current is carried by a double-wire system, the wires being placed on either side of the rail and collected in the usual manner by sliding bows. Considerable power is required in starting on account of the numerous curves and the weight of the train, and in order to allow the starting torque of

operator and locked automatically by means of a special device designed to strike against a jack, after which the trucks are immediately ready for another charge. Those cars designed for 1200 liters and less are tilted by hand by a releasing lever, but they are also automatically raised and fixed in position for a new charge. The suspended railway illustrated in the accompanying engravings was installed by A. Koppel, Ltd.

Slime Settling before Cyaniding

An efficient and novel method of slime settling has been developed by Horace G. Nichols¹. The principle involved is that of removing the solid matter as it reaches the bottom of the tank in which it is settled. The effect is two-fold. It is found that the solid matter settles very compactly when not allowed to accumulate, and its removal prevents the thickening of the liquid above, which is one of the principal causes of the slow and imperfect settlement of slimes.

It is well known that retardation is a function of the depth measured from the top of the still turbid portion of the liquid, to the bottom of the vessel, and an increase of suspended matter causes a decrease in the rate of subsidence².

When distilled or hot water is employed, there is a noted acceleration in the settlement of slime. This is due, doubtless, to the reduced density of the medium. This indicates the marked effects on settlement which may be produced by very small variations in the specific gravity of the liquid.

It occurred to the author that if, in place of providing a receptacle for settled slimes, such slimes were removed as fast as settled, the specific gravity of the medium would not be allowed to increase toward the bottom of the settler, and the settling would so be accelerated.

Experiments were made in British Columbia on an ore of quartz with argillaceous material containing about 2 per cent. of sulphide of iron, zinc and lead. Particular care was taken to separate out the heavier and coarser portions from the pulp to be used. This was effected by crushing in a stamp battery furnished with a very high discharge, and passing the pulp through a hydraulic classifier.

An apparatus consisting of a pyramidal tank about 4x5 ft. connecting at the bottom through an 8-in. square aperture with a closed box was constructed. A 10-in. belt, *C* in Fig. 1, was made to travel slowly in the closed box. A tank was provided with a trap door just above its connection with the box *B*. This door was arranged so that it could be opened from above as desired and so allow of free passage between the two vessels.

In carrying out the tests a charge of pulp from the agitator vat was run into the tank *A* and the trough *B* was filled with water up to the same level. While all the pulp was still in suspension, air agitation being used, the trap was removed and the belt run in the direction of the arrows at a speed of 4 ft. per minute. The solid matter was removed from the belt by a scraper.

It was found that the finest slime was carried out of the tank and discharged

by the belt. It did not tend to accumulate in the tank and under the belt. In some cases the average discharge of a finely crushed ore did not contain over 25 per cent. of moisture. When a pulp containing 40 per cent. of solid was treated the initial discharge carried only 22.5 per cent. of moisture. Such a discharge is more comparable with that of filters than with the product of settling tanks.

METHOD OF APPLICATION

It is found that in practice this method of slime treatment may be applied in one of two ways: (1) It may be used as an intermittent process in which a charge of pulp from an agitator vat would be run directly to a separator which would be of sufficient capacity to hold the whole of such agitator charge in addition to a residual charge from a previous operation. The object of this provision being to allow of extracting on the belt only such proportion of the solid contents of a separator charge as could be effected with the economic minimum of moisture. The belt discharge from this separator would be delivered into a second similar tank,

made for keeping a filter or screen surface free from accumulated caked slime, which may be done by providing an automatic periodic cutting-off of the suction applied to such filter or screen, and applying a small back pressure it is possible to withdraw continually clear solution from a pulp having as high a specific gravity as 1.4.

When the belt and suction are so correlated with regard to a given supply of pulp that when the one removes the solids the other takes out the proportionate amount of solution, a continuous supply of pulp can be kept running to the separator which would then always contain a charge of uniform specific gravity.

In applying this method to cyanide treatment, it may be noted that in other processes the completeness of washing is dependent upon time and capacity of the plant, inasmuch as each instalment of slime is taken separately and the washed solution passed through it as long as possible. Then it has to be removed, whether perfectly washed or not, to make room for the next succeeding instalment.

In the method described, continual progression through the plant is unimpeded,

FIG. 1. MACHINE FOR SETTLING SLIMES UPON AN ENDLESS BELT

with the addition of a weaker solution or of wash water, or of both. The liquid so added may be sprayed upon the discharging belt in such a way as to loosen and disintegrate the discharged slime, or a mixer may be added for that purpose.

After the withdrawal of the required proportion of the solid contents and classification of the solution left in the tank, the latter would be withdrawn either by decantation or suction, to the original level, thus permitting of the introduction of a second charge. (2) It may be applied as a continuous process by the simple introduction of a suction and filter. The percentage of moisture carried over in the discharge varies inversely with the percentage of solids in the separator charge. The first portions of a discharge from any given separator charge are always better than the succeeding portions. It consequently follows that if the density of a separator charge is maintained at its initial density the percentage of moisture in the discharge will be kept at a minimum and the rate of discharge will be materially increased. It has been found that when provision is

and the slime may be washed with any reasonable amount of weak solution desired, without in any way affecting the time of treatment, the only factor affected being the capacity of the extractor boxes.

The conveyer belt takes the place of the usual means of transference, such as pumps, carrying machinery, etc., which are employed for filtering slime. Gravity alone performs the separation by reason of the possibility of taking advantage of the principle of free settlement.

The separation of sands from slime is not called for. Consequently, the many disadvantages attendant upon attempts to deal with such classes of material as depend upon close classification are obviated. The best results from the treatment have been obtained from charges of high percentages of solids. It is probable that the only limit to the thickness of a charge is the point at which it will not run. This feature is of great importance as it is only necessary to run the charge from the agitator to the first separator and, consequently greater opportunities are afforded for preliminary decantation and thickening of the agitation charge.

Metallurgical Treatment of Mount Morgan Ores

The Chlorination Processes Employed Were Developed to Suit the Peculiarities of the Ores. Copper Ores Are Smelted in Usual Way .

BY J. BOWIE WILSON*

The Mount Morgan Company started with the usual stamp battery, but the poor recoveries soon convinced the management that this method of recovering the gold was quite unsuitable for the ores. The extreme fineness of the gold and the slimy nature of the oxidized material made it impossible to amalgamate a large proportion of the gold. After the battery had been found to be inefficient, experiments were made with Berdan pans, Wheeler pans, arrastres, Watson and

chlorination process was installed and the old lower and upper works were first erected for this method of chlorination.

The ore delivered from the mine was dry crushed in Krom rolls after having first been dried in revolving dryers. The finely ground ore was then calcined in reverberatory furnaces, 11x10 ft., taking a charge of about one ton and requiring about three hours to finish. The hot ore was cooled upon a large floor and then

and the gold precipitated upon charcoal bedded in filters.

About 1892 the barrels were superseded by the Hall-Richard method of chlorinating which consisted in leaching the calcined ore in open vats with a solution of chlorine in water, it having been discovered that the old idea that nascent chlorine was required to dissolve gold was erroneous, and also that an equally good extraction could be made in open vats as under pressure in the barrels. This of

MOUNT MORGAN COPPER WORKS—LOOKING NORTH

Denny pans and Chilean mills, but all without success.

Experiments were then made with different chlorination processes, and it was found that if the oxidized ore was first calcined the gold could be leached out with chlorine. The calcination was necessary to dehydrate the ore and to convert it into a leachable product. Finally a barrel-

trucked to revolving barrels holding about one ton, and water, bleaching powder and sulphuric acid added and the barrel slowly revolved for between two and three hours.

The barrels were made of hardwood and lined with lead. When the barrels had sufficiently treated the ore the charge was emptied into vats placed below and having a sand filter in the bottom, and the gold chloride was leached out with water

course led to a great reduction in the working costs as the barrels were heavy to wash and costly to keep in repair.

The chlorination process as used today was described in a recent issue of the JOURNAL. The description shows the improvements that have been made since the first chlorination plant was erected.

The chlorine for making the solution is generated in stills made of slabs of sandstone from manganese ore, salt, and sul-

*Mining engineer, Sydney, N. S. W.

phuric acid, the mixture being heated and kept mixed by jets of steam entering at the bottom of the sides. The chlorine gas is led in earthenware pipes to the bottom of concrete scrubbing towers where the gas rises against a falling stream of water and is absorbed by it. The strength of the solution used is generally 80 grains per gallon.

tralia where one furnace was erected, and thrown out of commission after a short trial.

These furnaces have given good working costs but their first cost is great and would have been prohibitive if it had not been possible to make firebricks locally. It can readily be understood that finely ground heated ore falling in showers

chute, 3 ft. x 10 in., in its center over which the ore trucks are emptied, so that a proportion of the ore falls through the bottom of the bin on the floor below and is taken as a sample.

The Queensland Government Railway has a siding to the top of these bins, so that all coke and limestone can be discharged directly into the bins. Each bin

WEST CHLORINATION WORKS HANDLING OXIDIZED ORES AT MOUNT MORGAN

The Engineering & Mining Journal, N. F.

MUNCIE WORKS AT MOUNT MORGAN—SECTIONAL ELEVATION

The Engineering & Mining Journal, N. F.

The muncie works was completed in 1900 and is constructed in two sections. The general arrangement of the plant is similar to that of the plant which treats the oxidized ore with the exception that, the ore being a sulphide, Richard's shaft furnaces replace the cylindrical calcining furnace. There are four of these furnaces in each section or eight in all. These furnaces were designed and patented by G. A. Richard, the general manager of the company, and have not been tried on any other works with the exception of that of the Boulder Main Reef Company in West Aus-

tralia where one furnace was erected, and thrown out of commission after a short trial. This is a great defect in the furnace.

The copper-smelting plant was completed in 1906, but it was enlarged in 1907 and now consists of four blast furnaces of which three are kept in blast and one in readiness to blow in. The bins for the storage of ore, iron ore, limestone and flux are built in rows four deep immediately behind the feed floor and parallel to it. There are 64 bins in all and in the first two rows each bin has a sampling

chute, 3 ft. x 10 in., in its center over which the ore trucks are emptied, so that a proportion of the ore falls through the bottom of the bin on the floor below and is taken as a sample.

On the feed floor the materials for the charge are weighed separately upon weigh-bridges in hand charge cars. The cars are tipped upon iron plates (water cooled) at the mouth of the furnace and the mixture is shoveled in.

The furnaces are built of two tiers of mild steel water jackets the bottom jackets being 7 ft. and the top 4 ft. high. There is 8 ft. of water jacketing above the tuyere level. Each furnace has 40 tuyeres spaced 9¼ in. apart and ¾ in. in diameter.

Open-Tank Method of Preserving Timber*

BY HOWARD F. WEISS†

The successful impregnation of wood with preservatives without pressure was first brought before the public in 1867 by Prof. Charles A. Seely, of New York. The principles which Professor Seely then described are the ones mainly followed in the process as it is employed at present, yet, owing to the low price of lumber and the comparatively inexhaustible supply of timber, the open tank process attracted little attention until in 1904 the Forest Service began to test this process at the Louisiana Purchase Exposition. At the same time a similar series of tests were made at this exposition by the promoters of the Guissani process, which is based upon principles almost identical with those used in the Seely process. There are, I believe, two commercial plants in Italy which are successfully treating wood by the Guissani process.

Since 1904, the Forest Service has carried on a number of tests in various parts of the United States in order to develop the open-tank method. Different kinds of wood have been tested, for all sorts of purposes, in cooperation with telephone, mining, lumber and railroad companies. As a result, enough information has been obtained to place this process on a sound, practical basis.

SEASONING WOOD

All wood is more or less porous, and contains various amounts of air and water. As no preservative can be forced into wood while it is thoroughly saturated with water, it is necessary to reduce the amount of moisture in it. In the open-tank method this is accomplished chiefly by air seasoning, but there are drawbacks to this method of seasoning owing to the large storage yards required, the considerable stock of timbers which is tied up, subject to fire risk and accumulating interest, and finally the demands of business often require that timber shall be treated as soon as possible after it has been felled in the woods. Besides, if timber not properly piled is held for a long period in the seasoning yard, it is liable to decay, especially if the atmosphere is warm and damp. On this account quicker methods of seasoning have been adopted especially since the rapid increase in value of lumber. There are two methods for quickly seasoning timber, seasoning by means of steam and seasoning by means of oil. The saturated steam method is practically the only one used now, for the difficulty of preventing

charring of the wood, when superheated steam is used has caused the abandonment of its use. The chief objection to saturated steam is that it does not dry out the wood, but only heats it; consequently a vacuum must be subsequently applied in order to remove the moisture from the wood. In the oil-seasoning method it is different, for when green wood is steeped in oil at a temperature above the boiling point of water, the water is evaporated and driven away. As yet few plants employ oil as the heating medium, but it seems highly probable that this method will come into prominence in the near future.

Oil drying is used in the open-tank method to prepare green timber for the reception of the preservative, but owing to the greater length of time and the greater expense of drying out wood containing 80 per cent. moisture than of drying out wood containing only 20 or 30 per cent., it is recommended for the open-tank process that whenever possible at least partially seasoned wood should be used.

ABSORPTION OF PRESERVATIVE

Wood consists of cells bounded by cell walls composed chiefly of cellulose. As yet all tests made to detect the presence of creosote in cell walls of timber treated with preservative have failed to find it there. If this is the case, then the preservative can only be absorbed into the cellular and inter-cellular spaces of the wood. In the open-tank process impregnation with a preservative is accomplished by heating the air and moisture in the cellular spaces of the wood and then cooling the timber while in a bath of the preservative. A partial vacuum is thus created in the cells, which causes the preservative to be sucked back into the cells. In practice all of the air and water cannot be driven out of the wood by heating, nor can a perfect vacuum be obtained by cooling. The maximum practical absorption, therefore, is always less than the theoretical, but an absorption of 38 lb. of oil per cu. ft., or an efficiency of 83 per cent. based on a theoretical absorption, has been obtained by the open-tank method with loblolly pine.

All parts of a piece of timber are not equally easy of impregnation with preservatives; for instance, sap wood can almost always be much more easily treated than hardwood. This resistance appears to be a problem entirely distinct from the density of the wood and may be due to the lignification of the cell walls, which would be greater in the older cells. It is safe to state that the sap wood of practically any species of timber can be completely impregnated by the open-tank process, but the amount of preservative injected per cubic foot can be varied without affecting the distance of penetration. In other words, a full or empty-cell treatment can be easily obtained. Tests made on loblolly pine props showed a penetra-

tion of $3\frac{1}{2}$ in., while the absorption of the creosote varied in amount from 6 to 18 lb. per cu. ft. The amount of absorption is controlled largely by the degree and duration of the heating and cooling periods. If held for a long time in hot oil and then submerged in cool oil until no further cooling takes place, the wood will be thoroughly saturated. If heated in hot oil and then submerged in cool oil for only a short period, the cells of the wood will be only partially filled with the preservative. This alternate heating and cooling of the wood can be carried on until complete impregnation results.

When it is desired to impregnate the timber with an aqueous solution, such as zinc chloride, it is first heated in oil and then submerged in a cold-water solution of that salt. Poles cut from Western yellow pine were treated in this manner in California, and the zinc chloride penetrated to a depth of 4 in. The absorption of dry zinc chloride varied from $\frac{1}{2}$ to 2 lb. per cu. ft. The amount of the absorption was controlled by the strength of the solution and the duration of the hot and cold baths.

The open-tank process of impregnation is well adapted to treating round timbers of any kind, such as stulls and posts, or for dimension timbers such as are used for other purposes about mines, but in this treatment it must be remembered that the heart wood is very hard to treat. It happens that the woods which are at present the most abundant and cheaper are almost always the ones best suited to preservative treatment. In a great many cases these can be more advantageously used than the more expensive varieties. Tests made in Louisiana without pressure on hot long-leaf-pine ties showed that the creosote had penetrated $1\frac{1}{2}$ in., which is a good treatment for this class of material.

COST OF DIFFERENT SIZES OF OPEN-TANK PLANTS

There are at present two general types of open-tank plants in use. In one, the wood is moved during the bath; in the other, the preservative is moved. The former is a simpler type and the one best suited for the treatment of small pieces of timber when a cheap plant is desired and the quantity of timber to be treated is small. These plants can be built for as little as \$5. Those commonly used by the Forest Service cost from \$35 to \$180 each and have a capacity of from 50 to 200 fence posts per day. When heavy, large timbers, such as mine props, poles, etc., are to be treated, it is cheaper to build a more expensive plant and to move the liquid rather than the wood. These plants are largely patterned after the pressure plants, but can be built at a much less cost on account of the lighter material and machinery used in their construction. A plant, including a treatment cylinder 50 ft. long and 6 ft. in diameter, will cost about \$800. Plants of this type consist

* Abstract of a paper presented at the convention of the American Street and Interurban Railroad Engineering Association, at Atlantic City, N. J., Oct. 12-16.

† Chief, Section of Research, Office of Wood Preservation, United States Forest Service, Washington, D. C.

of a horizontal cylinder of $\frac{1}{4}$ -in. steel, with swinging door locked by bolts. A small dome is fitted on the top of the cylinder and connected with a surface condenser, so that the vapors and oil which distil over during the hot bath can either be turned back into the treating cylinder or run to waste. The cylinder is fitted with a track for running the cars in and out, with steam coils for heating the oil, and with thermometers for recording the temperature. One or more closed measuring tanks are built either directly over or to one side of the treating cylinder, so that the preservative can flow by gravity. These tanks are fitted with a gage which shows the absorption of the preservative. A receiving tank is built in a pit so that the oil can run from the treating cylinder into it by gravity. The oil is then pumped back into the measuring or storage tank.

The open-tank process has been developed very recently and as yet many problems remain to be solved, but this is also true of the various pressure processes. In order to solve these problems the Forest Service is erecting in Washington, D. C., a laboratory which will be the most complete of its kind in the world. In it there will be retorts strong enough to permit of experimenting with preservatives when pressures as high as 500 lb. per sq. in. are used.

Precipitation of Gold and Silver by Soluble Sulphides

In answering the discussion of his article, "Some Futures of Silver Ore Treatment in Mexico," W. A. Caldecott (*Journ. Chem., Met. and Min. Soc. of South Africa*, July, 1908) describes the following experiment to test the possibility of reprecipitation of gold and silver from working solutions by soluble sulphides. A mixture of oxidized and pyritic gold-silver ores from the El Oro, Pachuca, and Guanajuato districts, Mexico, was used. The analysis of the mixed ore is as follows: Silica, 77.89 per cent.; metallic iron, 0.65; ferric oxide, 3.39; alumina, 5.73; lime, 5.52; magnesia, 1.33; sulphur, 1.61; carbonic acid, 1.97; water (loss on ignition), 2.02; total, 100.11 per cent.

The ore assayed 16.3 dwt. gold per 2000-lb. ton (equal to 27.9 grams per metric ton), and 490 dwt. silver per ton of 2000 lb. (equal to 840 grams per metric ton). The metallic iron shown in the above analysis was separated as such by magnet, and was, no doubt, introduced during fine-crushing on the iron bucking board. Part of the iron reported as oxide was probably combined with sulphur as pyrites.

All experiments were made on ore dry-crushed through a screen of 200 holes per linear inch. Hence the crushed ore was practically slimes from a metallurgical standpoint. By long boiling in strong

nitric acid, and then, after washing, in aqua regia, an extraction of 93 per cent. of the gold and 91.4 per cent. of the silver was obtained. Such a treatment would, of course, dissolve any base-metal compounds, as well as the gold and silver, which the preliminary fine-crushing had exposed to the action of these powerful solvents.

To test the possibility, indicated in my original paper, of reprecipitation, by soluble sulphides derived from the ore, of the gold and silver in solution, the following experiment was made: 100 grams of the above finely crushed ore was mixed with 200 c.c. of sodium-cyanide solution titrating 0.05 per cent. KCN and 1 gram lime, and the mixture shaken at intervals for six hours. The pulp was then halved into *a* and *b*. The half *a* had its solution, which contained free cyanide, at once filtered off and assayed. The half *b* was put aside in a small, closed flask, which it almost completely filled, for six weeks and shaken once weekly; at the end of this time the solution, which then contained no free cyanide, was filtered off and assayed. The results are shown in an accompanying table:

THE RESULTS OF EXPERIMENT ON REPRECIPITATION OF GOLD AND SILVER

Treatment.	GOLD DISSOLVED.			SILVER DISSOLVED.		
	Per Ton of Ore.	Per Cent. Extraction.		Per Ton of Ore.	Per Cent. Extraction.	
	Dwt. per 2,000-lb. Ton.	Grams per Metric Ton.	Per Cent.	Dwt. per 2,000-lb. Ton.	Grams per Metric Ton.	Per Cent.
a. 6-hours' treatment.	10.00	17.1	61.3	155	266	31.6
b. after 6 weeks.....	0.50	0.9	3.1	21	36	4.8
